A New Ingot Heating Furnace. *Iron Age,* Vol. 136, Nov. 21, 1935, pages 34-35. Describes furnace developed by Salem Engineering Co. Hole is circular in section, with charging opening 11 ft. in diam. and 7 ft. deep. Pit is fired by gas of about 500 B.T.U./ft.^{3} thermal value. Proper mixture of gas and air, and temperature of furnace are automatically controlled. Gives advantages of this type of furnace. VSP (6)

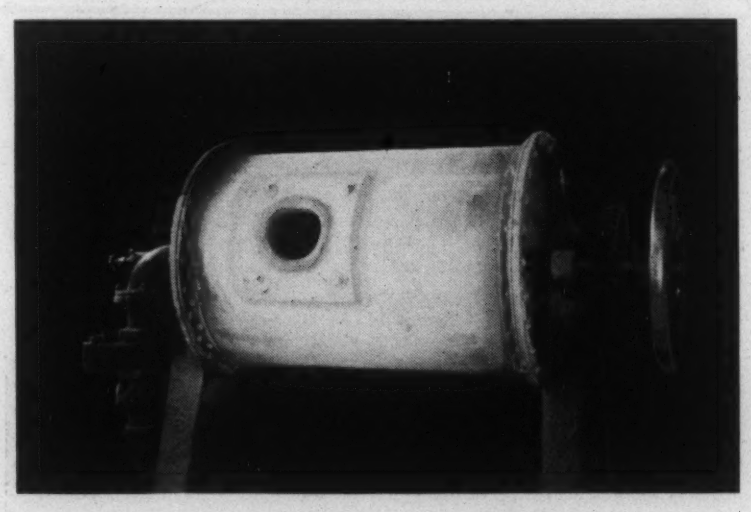
Furnace Design and Operation. *Heat Treating & Forging,* Vol. 21, Dec. 1935, pages 589-592. Discusses principles, advantages, operation and design of the Stevens open-hearth furnace, and gives results obtained in practice. MS (6)

High-Frequency Induction Furnace Steel Plant. *Engineering,* Vol. 140, Nov. 8, 1935, pages 513-514; *Electrical Review,* Vol. 118, Jan. 24, 1936, page 128. Describes furnaces recently installed at the Wicker Works, Sheffield, of Messrs. Samuel Osborn and Company, Limited. There are 2 high-frequency electric induction-furnace steel-melting plants. There are 4 furnaces in all, 2 of ½ ton capacity and 2 of ¼ ton capacity, each with its own tilting gear. The equipment is used in producing special heat- and corrosion-resisting steels and alloy steels such as Ni-Cr air-hardening and oil-hardening steels, Ni steels and Cr-V steels. MS + LFM (6)

Testing Metallurgical Fuel Oils. John H. Hruska. *Iron Age,* Vol. 136, Oct. 24, 1935, pages 20-23, 92. Author contends that an accurate check on the viscosity of fuel oil is more valuable than sp. gr., since gravity determinations give an inaccurate check of the suitability of oils for metallurgical purposes. Describes the Steiner test which is shown to be quicker and simpler in operation and also more accurate than the Saybolt viscosity test. Complete temperature viscosity curve may be obtained quickly even by unskilled worker. Includes table giving technological properties of fuel oils used in iron and steel industry. VSP (6)

Progress in Design and Application of Electric Furnaces. H. Knight. *Metallurgia,* Vol. 13, Dec. 1935, pages 53-56. Describes melting and heat-treating furnaces recently installed in England. JLG (6)

Metallization of Electric Furnace Electrodes. G. F. Morenko. *Domez,* No. 8, 1935, pages 39-45. In Russian. Plant experiments conducted on 5 ton arc furnaces using 225 mm. electrodes coated with Cu and with Al by Schoop process showed that the Al coating did not offer any protection and Cu coating reduced the average electrode consumption from 12.05 kg./ton to 10.67 kg./ton. The figures were obtained as the result of 3 heats in which one of the electrodes was coated, two others being plain carbon electrodes. Al does not protect because it oxidizes too soon and forms an inadhesive oxide. (6)



Hausfeld Barrel Type Open-Flame Furnace for the melting of non-ferrous metals.

Glad to tell about . . .

P. B. SILLIMANITE

RAMMING MIX

"Any inquiries that we receive from your prospective customers will be given our immediate attention," writes The Ohio Pattern Works & Foundry Company.

Many others are finding P. B. Sillimanite Ramming Mix giving unusual satisfaction in **Iron Melting Furnaces**—Complete linings in rocking type, indirect arc electric furnaces. Roofs and side walls in small direct arc electric furnaces. Crucible furnaces. Barrel type furnaces. Also in **Brass Melting Furnaces**—Complete linings in indirect arc electric furnaces. Crucible furnaces. Oil and gas-fired non-crucible or open-flame furnaces.

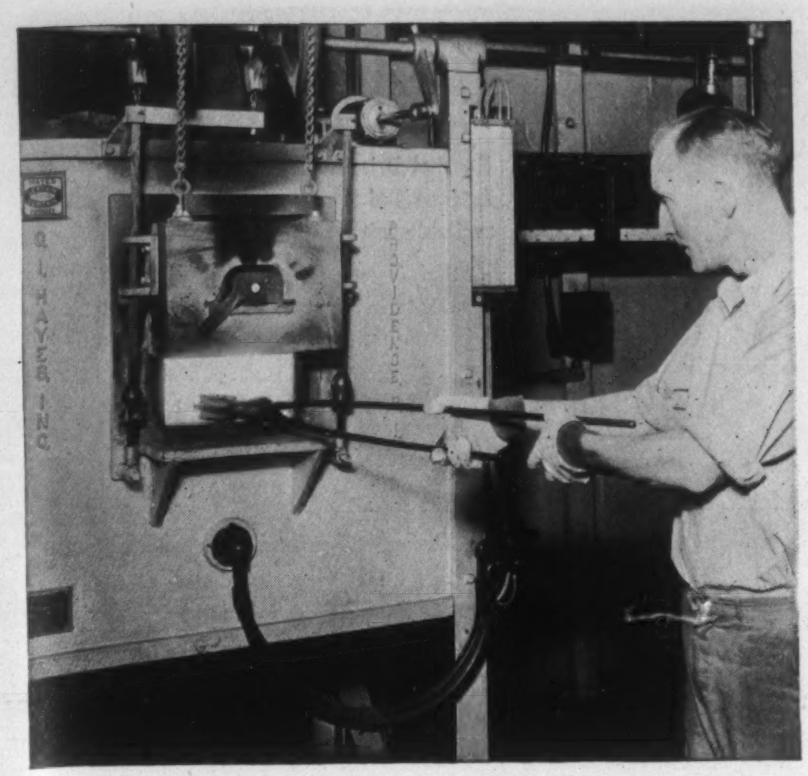
Tell our Engineering Department what you have in mind—it will be to your advantage.

TAYLOR P B SILLIMANITE

Look for this trade-mark on P. B. Sillimanite—your assurance of unusual satisfaction.

It's for you—a handy data and fact file of P. B. Sillimanite proven possibilities—ask for it.

THE CHAS. TAYLOR SONS CO.
CINCINNATI, OHIO



They investigated the LEADER and profited greatly thereby

The John Bath Company, makers of highest-grade ground-thread tools, "had no furnace problem." They had no spoilage trouble, no difficulty with surface defects, their heat treating was up to the very highest standards.

Yet, consistent with their reputation for quality, they are definitely open minded toward new products or processes which can help them safeguard or enhance that quality. They investigated "Certain Curtain" furnaces. Investigation led to installation. Installation soon proved that the furnaces quickly repaid their cost through reduced hardening expense, and paid an extra dividend in the form of a small but definite increase in working quality.

"Certain Curtain" furnaces offer a superior degree of precision in hardening because of their patented atmosphere control. No matter what the nature of a firm's hardening problems, they can best be solved by the furnace which provides the best control—and that is why "Certain Curtain" has become the LEADER in its field.

Continuous Precision Annealing

When you anneal glass, you want precision as well as reliability in the annealing. That is why the large continuous glass lehr shown above in the plant of a large and well known optical company is equipped with a Spencer Turbo-Compressor for the air service.

Spencer Precision is due to the inherent characteristics of the Centrifugal Compressor which automatically maintains constant pressures.

Spencer Reliability is traceable to the simplicity and strength in the construction. There are only two bearings. Duraluminum impellers operate with wide clearances. Each unit is individually balanced. You can stand a coin edgewise on the turbo casing while the unit is running.

These precision characteristics have been known to steel, ceramic and other industrial engineers for nearly a quarter of a century.

Because of the growing application of precision control on every-day production-operations metallurgists, production engineers and manufacturers of gas and oil-fired equipment are more insistent than ever before in their recommendation of Spencer Turbos.

THE SPENCER TURBINE COMPANY, HARTFORD, CONN.

Six-Station Vertical Turret Machine Used in Case Hardening Staybolts. *Steel,* Vol. 98, Jan. 27, 1936, pages 49-50. Flannery Bolt Co., Bridgeville, Pa., employs a specially-constructed machine to case-harden heads of flexible forged steel staybolts on a continuous basis. It is provided with 6 arms, each having a bolt chucking mechanism suspended at the end. Each chucking mechanism can accommodate 45 bolts. The 6 stations of turret are loading, preheating, final heating, quenching, washing, and unloading. Machine is entirely automatic in its operation. MS (6)

Refractories Meeting New Demands. *Steel,* Vol. 98, Jan. 6, 1936, pages 237, 335-336. Review of progress in the refractories industry in 1935 as seen by various authorities. MS (6)

Top-Charge Melting Unit Handles Bulky Scrap. *Steel,* Vol. 98, Jan. 13, 1936, pages 41, 72. Describes top-charge electric furnace developed by the Pittsburgh Lectromelt Furnace Corp. Roof operates in a horizontal plane instead of tilting. Lifting and swinging aside of roof is done by a powerful ram from a stationary cylinder separate from furnace shell. Results with this furnace in actual operation show lower power cost, 30% less refractories cost, and 14-35% lower electrode consumption, compared with fixed-roof furnaces. MS (6)

Gas Furnaces for Forging Plants. *Machinery,* N. Y., Vol. 42, Jan. 1936, pages 332-333. A furnace for a scheduled performance with controlled atmosphere to reduce decarburization of the surface of the forgings is described. Ha (6)

Investigation of an Electrically Heated Enameling Furnace (Untersuchung an einem elektrisch beheizten Blech-Emaillierofen) H. MEYSENBURG. *Elektrizitätswirtschaft,* Vol. 34, Sept. 15, 1935, pages 576-581. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 13L/10. WH (6)

The Supply of Acetylene for Industries. A. MCMILLAN. *Iron & Steel of Canada,* Vol. 18, Dec. 1935, pages 91-94. The properties of the oxy-acetylene flame and its industrial uses are explained and the sources and manufacture of Ca carbide in Canada are described. Ha (6)

Malleable Furnace Refractories. L. C. HEWITT. *Foundry Trade Journal,* Vol. 53, Oct. 10, 1935, page 280. See "Notes on Refractories for Electric Furnaces Producing Special Irons," *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 13L/8. AIK (6)

Application of Electrical Heat in Ferrous and Non-Ferrous Industry with Particular Reference to the Saar District (Elektrowärmeanwendung in der Eisen- und Metallindustrie insbesondere im Saarland) W. RODENHAUSEN. *Elektrizitätswirtschaft,* Vol. 34, Oct. 25, 1935, pages 670-675. Paper before the Annual Meeting of the German Power Plant Associations, Sept. 1935, at Saarbrücken, gives data on the extent to which electric furnaces are in use in metal industry in the Saar Basin. The various furnace types are described. The picture of a 4 ton, 350 kw., 16 Hertz, cos $\Phi = 0.55$ vacuum furnace, type Rohn, as well as other German resistance, induction and arc furnaces are shown. WH (6)

7. JOINING

■ 7b. Welding & Cutting ■

E. V. DAVID, SECTION EDITOR

Welding as Applied to Shipbuilding. C. S. Lillicrap. *Welding Journal,* British, Vol 32, Nov. 1935, pages 329-331. Successful welding on large scale is considered to be a difficult matter and the literature on welding should contain a record of welding failures in order to advance the art by study of the unsuccessful cases. For thick plating the butt joint should be used while for thin plating the lap joint is the better at present. Bare wire welds should be restricted to joints with known small stresses and not subjected to shock or dynamic loading. Small diam. electrode and multiple passes are favored over larger electrode and single pass. Discussion brings out opinion that welded butt joints in shipbuilding have better fatigue resistance than riveted butt joint. WB (7b)

European Specifications for Heavy Welding. Federico Giolitti. *Metal Progress,* Vol. 28, Dec. 1935, page 54. Discusses European requirements for coefficient of load in weld to base metal load, electrodes and welder qualifications with some light on their evolution in various countries. WLC (7b)

Electric Arc Welding and Its Application. IV, V. M. le Brun. *Welding Journal,* British, Vol. 32, Sept. 1935, pages 277, 280; Oct. 1935, pages 294-297, 316. Discussion of electrodes, current consumption, rod coatings and structure. WB (7b)

Designers' Problems with Welded Steel in Machine Tools. Robert E. Kinkead. *Machine Design,* Vol. 7, Sept. 1935, pages 46-49. Typical illustrations of welded machine tool members are shown and problems involved in the adoption of welding in this engineering field are critically discussed. WH (7b)

The Welding of Copper-Nickel-Molybdenum Steel. Howard L. Miller. *Welding Journal,* N. Y., Vol. 14, Dec. 1935, pages 28-30. Use of high tensile steel for fabrication of auto truck and tank bodies is discussed. Reduction of 30 to 50% in gage of sheets over former sheets of common steel used is cited as necessitating welding to use full strength of metal. Elimination of air hardening strengtheners Cr, Si, V makes possible ductile weld. Representative analysis of low C grade is .095 C, .70 Mn, .017 P, .028 S, .03 Si, 1.44 Cu, .75 Ni, .07 Mo, with yield of 69,800, tensile 82,400. elongation in 2" of 32%. A progressive survey of Rockwell B hardness across butt and lap welds shows only slight increase in hardness in heat affected zone over that of parent material and the hardness of the disturbed zone is of the same order as that of the weld itself. Drop tests on large tanks were made to show impact resistance and ductility of welded seams. Several truck and tank bodies fabricated by welding are shown in photos. WB (7b)

Progress in Welding Large Railway Bridges. O. Bondy. *Railway Gazette,* Vol. 63, Sept. 27, 1935, pages 492-497. The bridge carrying the German State Railway over the strait between Stralsund and the isle of Rügen is the largest plate girder bridge yet built by welding. It represents important advances in welding practice and in the testing of welds. As a first example of the innovations resulting from the progress in welding practice reference is made to new rolled sections for the flanges of welded plate girders. The dimensions of the novel "Nasenprofil" or bossed and grooved rolled sections are given. It is only necessary to insert the web in the grooves of the bossed flange plates and make 4 fillet welds. The new structural members are the outcome of prolonged experience in the fatigue testing of welded girders. The rounded form of the completed weld is a decisive technical advantage. The small thickness of the web compared with the flanges is another noticeable feature. A standard practice in Germany is that welds of railway bridges are inspected by X-rays using a working voltage up to 250,000 volts. A new "general exposure method" now enables a large area to be examined at once (52.5 ft. examination by a single exposure) and the requisite preparations can be completed in about 10 minutes. Magnetic clamps hold the wrapped films securely even on overhanging surfaces. About 25% saving in weight and about the same saving in cost were effected by the welded structures as compared with riveted ones. One of the latest methods of welding lengths of web plate in long span bridges is by means of the swallow-tail joint, which increases the weld, reduces the stress on the weld metal and avoids the use of straps covering the joints. WH (7b)

Resistance Process Applied to Welding Copper-Plated Steel Tubes. *Iron Age,* Vol. 136, Oct. 24, 1935, page 35. Describes 2 resistance welding machines for Cu-plated steel tubes of the Thomson-Gibbs Electric Welding Co. One machine is used to weld a double Cu-plated steel tube which is part of an automobile fuel feed system. Other machine is more unusual because welding transformer serves as a heating unit and does a faster job than was formerly done in electric furnace. Heating unit is linked with a forming machine which shapes tube from flat strip steel. As tube leaves forming machine it is pushed through heating unit where Cu coating is melted and steel fused into tight joint. VSP (7b)

Gas-Fusion Welding in the Repair Work of the German State Railways (Gasschmelzschweissung in Reichsbahn-Ausbesserungsbetrieben) A. Matting. *Autogene Metallbearbeitung,* Vol. 28, Dec. 15, 1935, pages 376-377. Applications of welding, cutting and surface treating are briefly discussed. Ha (7b)

PARTS *PROFITABLY* CUT

with the Airco-DB TRACTOGRAPH

Quickly, and much more accurately than with a hand torch, the TRACTOGRAPH enables you to gas cut straight, circular or irregular shapes over extended areas from steel up to two inches in thickness.

The ease and accuracy with which the TRACTOGRAPH can be guided along the scribed line, its positive traction and its ability to cut square corners, all combine to speed production and to lower costs in cutting steel plates.

Complete operating and design details in the TRACTOGRAPH Bulletin; we will be glad to send you a copy.

Applications of Oxy-Acetylene Welding (Applications de la Soudure oxyacétilénique). Granjon. *Usine,* Vol. 44, Oct. 10, 1935, page 34. General review of oxy-acetylene welding and comparison with other methods. Except for Fe, welding of all metals including Al, Cu, bronze, nickel silver, is better done with oxy-acetylene than with any other method. Ha (7b)

The Organization of Welding in France. R. Granjon. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 2, pages 223-225. Brief description of school of welding in France. Points out that oxy-acetylene welding has a large field. JLG (7b)

An Electrically-Welded Heavy-Duty Mobile Crane. R. G. Griffin. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 565-571. Describes the crane and some details of the welded structures. JLG (7b)

Arc-Welded Bridge Girders Tested to Failure. La Motte Grover. *Engineering News-Record,* Vol. 115, Sept. 19, 1935, pages 392-394. Two 54" plate girders, 27′ long with butt-welded flange splices, showed no distress in welds and good stress distribution among component parts up to the point of failure. CBJ (7b)

Symposium on the Welding of Iron & Steel. Vols. I and II. Iron & Steel Institute, London, 1935. Cloth, 5½ x 8½ inches, 676 and 974 pages respectively. Price £2 2s (set of two volumes).

In February, 1934, Dr. H. J. Gough of the N.P.L. suggested that information on welding ought to be brought together. The suggestion was taken up by the Iron & Steel Institute, in coöperation with 15 other technical and engineering societies, and in May, 1935, the Symposium was held, with 116 papers preprinted. The present volumes contain some 150 papers.

This was extremely quick work, and many of the papers were obviously written under pressure. A vast deal of information is included, but, with so many authors, is necessarily presented in somewhat patchy fashion. The papers were grouped under four headings: 1. Present day practice and problems of welding in the engineering industries, comprising bridge and structural engineering, pressure vessels, railway material, ship building, aeronautical, automobile, chains, electrical and heavy engineering, iron and steel castings and wrought iron. These, with a few introductory summaries and a little discussion, form vol. I.

Vol. II contains group 2, welding practice, technique and apparatus, group 3, the metallurgy of welding, and group 4, specification, inspection, testing and safety aspects.

Group 3 has 29 papers, many of which center around the problem of coatings for welding rods.

In rather disjointed fashion, a huge amount of useful information is presented and anyone interested in welding from any aspect will find several papers of value. The total of 1650 pages is a large dose, only slightly mitigated by the various introductory summaries, if one seeks to get a general view of the welding industry and its problems.

The preface, by the President of the Iron & Steel Institute, recognizes this and remarks that the Organizing Committee is considering precisely what has emerged from the Symposium, and is to draw conclusions therefrom and recommend the trend of research to improve the art and science of welding, in a report to be published later. That will facilitate digestion by the general reader of this mass of data and opinion, and will serve to temper some of the individual ideas expressed in the papers themselves. While there was some discussion, all these papers were presented in two days and there was not time for the usual amount of enlightening discussion that the English usually append to printed technical papers.

The Symposium is a mine of information and even though the ore needs concentration, it is rich ore. H. W. Gillett (7b) -B-

French Specifications for Alloy Materials for Acetylene Welding (Französische Vorschriften für die Zusatzstoffe für die Azetylenschweissung) Kemper. *Autogene Metallbearbeitung,* Vol. 28, Dec. 1, 1935, pages 363-364. The materials and their physical properties permitted in the new French standards for the various welding and brazing processes are discussed and described. Ha (7b)

Carbon Electrodes in Welding (Kohle-Elektroden in der Schweisstechnik) Golther. *Elektrowärme,* Vol. 5, Dec. 1935, pages 300-301. In general 3 C types are used, all with or without core of C powder or special additions: (1) hard, amorphous C electrodes for all purposes and normal stresses; (2) medium hard or soft, graphitic electrodes which can be used for larger currents because of their graphite content; (3) electrically graphitized carbons having the least burning loss and highest electric conductivity. They will stand twice as much current load as the amorphous C and are used where very thin electrodes are required for making thin and neat seams. All electrodes may also be used with Cu coating. Diameters required for various currents are given and the fields of application of the C arc discussed. Ha (7b)

New Welded Rail Connection (Ein neuer geschweisster Schienenstoss) H. Görlich. *Elektrowärme,* Vol. 5, Dec. 1935, pages 296-297. The 2 rail ends are butt welded with circular incisions in the foot which makes for excellent strength in the welded joint. Ha (7b)

Welded Pressure Vessels. R. K. Hopkins. *Transactions American Institute of Mining & Metallurgical Engineers,* Vol. 117, 1935, pages 387-398. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 16L/7. (7b)

Repairs to, and Construction of, Gasholders by Electric Welding. H. H. Hollis. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 233-241. Review of practice in England. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 16L/9. JLG (7b)

Quality of an Autogenous Weld as Dependent on Type of Welding and Subsequent Treatment (Güte der Autogenschweissung in Abhängigkeit von Schweissart und Nachbehandlung) H. Holler & H. Frankenbusch. *Autogene Metallbearbeitung,* Vol. 28, Nov. 15, 1935, pages 337-344; Dec. 1, 1935, pages 359-363. Extensive tests with different kinds of steel demonstrated the very great influence of the alloy welding rods and the effect of hammering on notch-toughness and bending angles which reached a strength of 100%. It is, therefore, imperative that in all welds of high quality, the correct welding rod is used and the seam is hammered. All experiments are described in detail. Ha (7b)

Distortion Control Procedure. David Boyd & Gordon Cape. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 2, pages 39-49. Gives general outline of technique and procedure used by authors in fabricating heavy weldings. See also *Metals & Alloys,* Vol. 6, Oct. 1935, page MA 403L/8. JLG (7b)

Ship Welding and Classification Requirements. J. L. Adam. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 2, pages 667-676. Discusses welding practice in British ship yards and classification of welds. See also *Metals & Alloys,* Vol. 6, Oct. 1935, page MA 403L/10. JLG (7b)

Welding in the Electrical Industry. E. C. Davies. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 549-555. General discussion of the relative desirability of welded structures and castings in medium and heavy electrical equipment. JLG (7b)

Micro-mechanical Study of Welds. Pierre A. Chevenard & Albert M. Portevin. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 2, pages 333-352. A machine for testing small specimens in tension, shear, or flexure is briefly described. It tests specimens 1 or 1.5 mm. in diameter and stress-strain curves are plotted optically. Tests through welds in several different steels welded by several methods are described. Shear tests at short intervals along a rod taken perpendicular to the weld show the properties of the weld and the influence of welding on adjacent material. JLG (7b)

Welding in Relation to Automobile and General Repair Work. C. W. Brett. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 481-488. General discussion with particular attention to welding of automobile blocks. See also *Metals & Alloys,* Vol. 6, Oct. 1935, page MA 402R/10. JLG (7b)

The Advantages of Welding in Structural Steelwork. Oscar Faber. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 91-94. Brief discussion of the relative advantages of welding and riveting. JLG (7b)

Design of Welded Structures with Special Regard to Erection on the Site. F. Faltus. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 95-102. Describes some structures. JLG (7b)

Continuous Welding of Exposed Mains as Applied to the Goldfields Water Supply of Western Australia. Norman Fernie & Reginald J. Keating. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 215-225. Describes application of welding to renovations of a 30" steel conduit. The original main was laid below ground and Pb jointed. To eliminate leakage and corrosion due to Pb joints and saline soils, the renovated main was laid above ground without cover and continuously welded. JLG (7b)

Principles and Application Possibilities of the Individual Electric Welding Processes (Grundlagen und Anwendungsmöglichkeiten der einzelnen elektrischen Schweissverfahren) K. Siemers. *Elektrowärme,* Vol. 5, Dec. 1935, pages 289-292. Classification of electric resistance and electric arc welding processes, their equipment and characteristics are discussed. Ha (7b)

Application Possibilities of the P-Beam by Means of Welding Technique (Verwendungsmöglichkeiten des P-Tragers mit Hilfe der Schweisstechnik) J. Sehring. *Autogene Metallbearbeitung,* Vol. 28, Dec. 15, 1935, pages 375-376. The mechanical and architectural advantages of the welded P-beam (in fact a box-type beam) are pointed out and ways to weld it together from simple structural profiles and sheets described. Ha (7b)

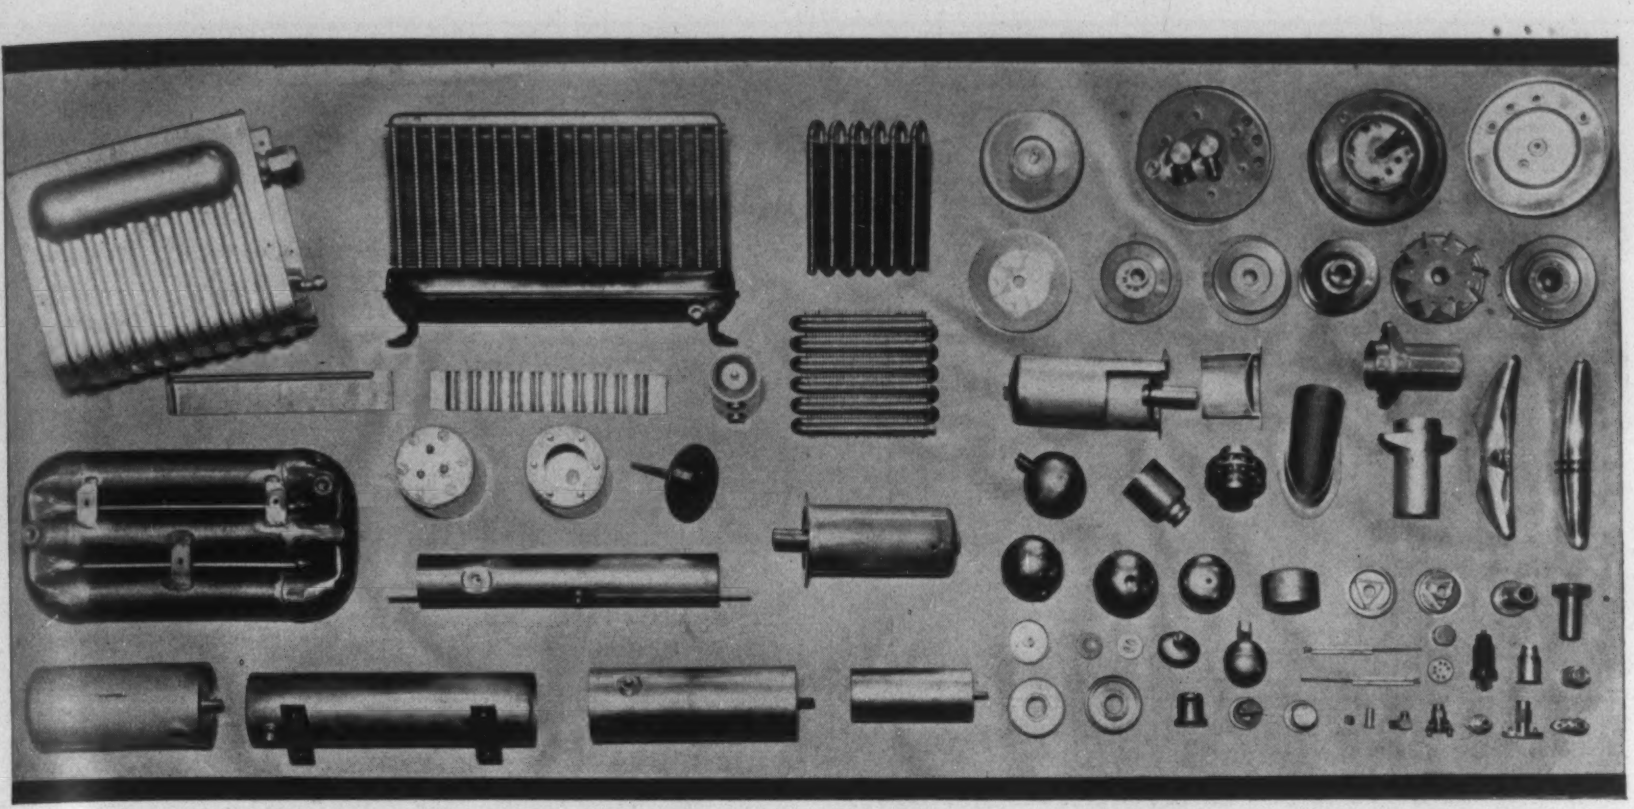
Use of Welding in the Manufacture of Freight Cars (Die Anwendung der Schweissung im Güterwagenbau) J. Schinke. *Zeitschrift Verein deutscher Ingenieure,* Vol. 79, Dec. 7, 1935, pages 1459-1466. Detailed description of design and construction with tables for different types of cars with savings in weight. Ha (7b)

Importance of Research in Welding Technique (Bedeutung schweisstechnischer Forschung) W. Adrian. *Autogene Metallbearbeitung,* Vol. 28, Dec. 1, 1935, pages 353-359. The influence and value of cooperation in this field is emphasized, progress made in knowledge on effect of shape, material, processes and sequence of procedures on the quality of welds is discussed, and some particularly interesting applications for welded structures are described. Ha (7b)

The Welding of Copper. H. Martin. *Aluminium & the Non-Ferrous Review,* Vol. 1, Oct. 1935, pages 40-41. Brief notes on the operation. JCC (7b)

Fabricated Composite Dies. K. Janiszewski. *Welding Journal,* N. Y., Vol. 14, Nov. 1935, pages 7-9; *Iron Age,* Vol. 136, Dec. 12, 1935, pages 25-27. Discussion of fabrication by cutting with oxy-acetylene flame and assembly by welding. Advantages cited are lower cost by this method, variety of shape and size obtainable, rapid fabrication, delivery after 1 or 2 days, less machining, less risk of cracking in hardening, distortion correction possible at low cost, higher hardness, alteration possible without rehardening and other advantages. WB + VSP (7b)

New Method for Welding Together Ferrous Metals by Application of Heat and Pressure. Leonard C. Grimshaw. *Metals Technology,* Jan. 1936, *American Institute Mining & Metallurgical Engineers Technical Publication* No. 667, 20 pages. Details of a new commercial method for uniting any ferrous materials are given. The material is cleaned to remove all oxide film, plated with Fe electrolytically, and welding is then performed by the application of heat and pressure. When welding 2 pieces together a metal seal is welded across the junction so that electrolytic Fe will not be oxidized in heating. Examples of high-speed steel welded to soft steel by rolling or forging are shown. Many micrographs are shown to illustrate the near perfection of the weld. The weld zone is free from non-metallics. On reheating after welding the bond is strengthened because of continued diffusion of alloying elements into the soft-Fe bond. 16 references. JLG (7b)

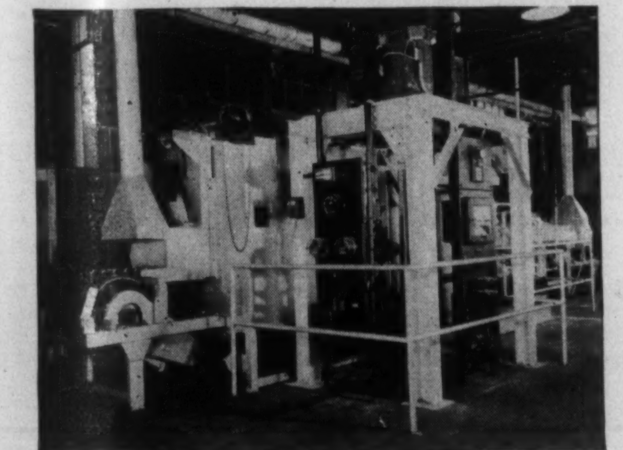


A few of the various parts and products being joined by the electric furnace copper brazing process — products ranging from small metal radio tube parts to large automotive and refrigerator units are being joined neatly, securely and economically by this process.

Join Your Metal Parts— Neater, Cheaper and Stronger

—by the continuous furnace brazing method

Metal parts in various shapes and sizes—ferrous and non-ferrous—are being joined neatly, securely and economically in continuous brazing equipment similar to that shown at left.



The assemblies are loaded on a conveyor at charging end of furnace as shown above—

—and without further attention are carried thru the furnace and discharged — securely joined — clean and bright.

The assemblies are loaded on a traveling belt, carried through this equipment in our special, inexpensive atmosphere and discharged, securely joined—clean and bright.

Products difficult or expensive to make in one piece can now be made in several pieces and joined—thus not only reducing the cost but actually improving the quality and appearance. Products requiring several stampings joined or requiring screw machine parts, forgings and stampings to complete the unit, can be neatly and economically joined right in the production line in your own shop.

Any number of joints in the same product or any number of pieces can be joined at one time. The most intricate parts or assemblies are made to actually "grow together," and joints made which are as strong, or even stronger than the original parts. On some parts it is possible to anneal and braze in one operation.

We will be glad to give you additional information, put samples of some of your products through this equipment to show you the results you can expect, and give you an estimate on the cost of the equipment to handle your production, together with operating cost, etc.

Investigate the brazing process for your products. You can join metal parts, neater, cheaper and stronger by this method.

Our engineers will be glad to discuss with you our new developments in controlled atmosphere furnaces for brazing, bright annealing or scale-free heat treating equipment, or work with you on any of your other furnace or heat treating problems.

Discussion of Paper by A. E. Gibson on "The Development And Use of Low Alloy High Tensile Steels". R. A. Bull. *Welding Journal,* N. Y., Vol. 14, Nov. 1935, pages 9-10. It is pointed out that in the case cited by Gibson of good service obtained by redesign of heavy duty clam shell buckets using welded alloy steels in place of steel castings, the most important factor was the change from poor design to good design. The implication is that properly designed steel casting would also have given good service and the satisfactory use of cast steel crankshafts is cited as example of good design and proper foundry practice. WB (7b)

Comments on Mr. R. A. Bull's Discussion of Mr. Gibson's Paper. *Welding Journal,* N. Y., Vol. 14, Nov. 1935, page 10. In particular design used for the bucket it was impossible to avoid abrupt changes in sections. It would take foundry considerable time to gain the experience necessary to produce sound casting of this design which would pay with quantity production as aim, but the item is a special order. The manufacturer guarantees the welded design against failure and considered any cast product as not 100% reliable, therefore not safe to guarantee. WB (7b)

Arc Welding. David Boyd. *Canadian Chemistry & Metallurgy,* Vol. 20, Jan. 1936, page 22. A brief discussion of a.c. and d.c. welding WHB (7b)

New Uses of Welding. C. W. Brett. *Electrical Review,* Vol. 118, Jan. 31, 1936, page 159. Electric welding has been used recently for erecting hulls of vessels; fabricating machinery and automobiles; building up worn rails, points, and crossings; joining rails to eliminate fish-plates; fabrication and repair of railway rolling-stock; repairing and strengthening bridges; reconditioning gas-holders; and repair of steel frames. MS (7b)

Modern Methods for Repairing Non-Ferrous Metals and Alloys. C. W. Brett. *Aluminum & the Non-Ferrous Review,* Vol. 1, Oct. 1935, pages 38-40. Welding of Al and Cu alloys is discussed and examples of its use in repairing automobile castings illustrated. JCC (7b)

Methods of Minimizing Distortion In Light Gage Steel. J. H. Blaha. *Welding Journal,* N. Y., Vol. 14, Nov. 1935, pages 18-22. In the manufacture of food liners for electrical refrigerators, the unit is built up from formed 20-22 gage sheet steel which is required to be porcelain enameled after fabrication and welding by gas flame. C content of .02 to .04 max. is required for sheet for good enamel surface and welding rod is of same material in form of 1/8" strips clipped from sheet material. Distortion due to welding butted corners is prevented; jigs completely supporting the sheet, top and bottom and rigidly clamping all metal adjacent to weld. Closely fitting cast Fe blocks are used for jigs which are sometimes water cooled. Retraining of welders is necessary in order to turn out satisfactory sheet metal weld since welders experienced in heavy section welding must change their technique entirely to prevent burning or distorting the metal. In the discussion of porcelain firing the implication is that with best care in butt welding of the food liner it may be finally rejected due to thermal shock of porcelain and steel when firing is done in box type of furnace while in continuous type furnace the same care is given the liner as was the case in welding. WB (7b)

Welding of Porcelained Steel. J. H. Blaha. *Industry & Welding,* Vol. 7, Dec. 1935, pages 27-31. Particular precautions to observe in this work and procedure are described. Ha (7b)

Electric Welding in the Construction of Electric Furnaces (Elektroschweissung im Elektro-Ofenbau) H. Bauer. *Elektrowärme,* Vol. 5, Dec. 1935, page 295. Brief description of design details. Ha (7b)

Welding Low Alloy Steels In the Pressure Vessel Industry. E. C. Chapman. *Welding Journal,* N. Y., Vol. 14, Nov. 1935, pages 2-6. Heat treatment by stress relieving for low alloy steels is essential to bring out their superior properties. For boiler construction the 70,000 lbs./in.^{2} min. tensile strength steel is relatively new class of steel for fusion welding accepted by A. S. M. E., and is supplanting 55,000 lbs./in.^{2} material for normal boiler operation. To obtain the higher figure the C was increased to .35 max. and Mn to .90 without other alloy additions. The practical limit of C is determined by quenching effect of parent metal and the criterion of how high it should be is that sufficient ductility restoration in weld and affected zone shall be obtained after stress relief. Stress relieving temperature of weld metal controls tensile strength in same way as the draw after a quench and low alloy steels with tensile strengths up to 90,000 lbs./in.^{2} with 20% ductility in 2" are an actuality. Opinion is that 100,000 lbs./in.^{2} material with 20% ductility will soon be available. Important factors in welding low alloy steels are: (1) affinity of an element for O_2 in controlling % in weld, (2) type of rod giving large recovery and low O_2 and N_2 content in weld, (3) air hardening, (4) red shortness, (5) effect of alloy on metal pool to promote gas evolution and smooth bead. Ti found beneficial in reducing air-hardening of Cr steels but is very active and tends to burn out, Cb is less active. The use of Si in less than 1% amounts is being used in low alloy steels for oxidation resistance and this development is considered to be in the experimental stage. General discussion is made of the Ni steels of 3% or below, 5% Cr steels and the effect of Mo additions of less than 1% to C and Cr steels. In welding 5% Cr steel it is preferable to preheat to above 300° F. before welding and to anneal before structure has cooled after welding. By heating to 1400°-1550° F., furnace cool, the hardness can be dropped from 300 Brinell to below 200. Photos are shown of test specimens of 5% Cr-.5% Mo, low Mo, Cromansil, .30% Cr-1.25% Ni and low Mo-V steels together with X-ray and macro photos. WB (7b)

Welded Highway Bridge Trusses of 150-Ft. Span. George L. Dresser. *Engineering News-Record,* Vol. 116, Jan. 2, 1936, pages 40-41. Details of an all-welded bridge consisting of 2 Pratt truss spans are discussed. CBJ (7b)

Autogenous Technique in Shipbuilding (Autogentechnik im Schiffbau und Schiffbaubetriebe) Dorn. *Autogene Metallbearbeitung,* Vol. 28, Dec. 15, 1935, pages 369-375. Equipment and processes for autogenous welding and cutting are described and illustrated by examples. Ha (7b)

Test Proves Impact Value of Welds Made by the Electric Arc. A. F. Davis. *Welding Journal,* N. Y., Vol. 14, Dec. 1935, page 19. Large scale, practical test of impact resistance of weld in 1/2" thick plate, built-up 12" box section tested by repeated dropping of 1800 lb. weight. Ductility of weld and lack of cracking is evident from photo. WB (7b)

Welding and Cutting High Chromium Steels. W J. Priestley. *Welding Journal,* N. Y., Vol. 15, Jan. 1936, pages 14-17; *Oxy-Acetylene Tips,* Vol. 14, Dec. 1935, pages 269-273; *Metal Progress,* Vol. 28, Dec. 1935, pages 56-58. Improved methods based on properties of Cr alloys. Effect of Cb and Ti on mechanical properties of Cr and Cr-Ni steels. Addition of these semi-rare elements prevents air-hardening, increases ductility, reduces annealing time and improves weldability. Oxyacetylene welding and cutting of various classes of Cr and stainless steels described. EVD + Ha + WLC (7b)

Rail Welding. L. J. Turner. *Industry & Welding,* Vol. 7, Dec. 1935, pages 13-14, 34-36. Maintenance and reforming of rails by surface fusion welding and building-up are discussed, procedures are described. Ha (7b)

The Control of Electric Resistance Welding. P. W. Townsend. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 2, pages 189-196. Describes various control systems that have been developed. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 16R/4. JLG (7b)

Aircraft Constructional Welding. R. F. Taylor. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 459-464; *Sheet Metal Industries,* Vol. 9, Aug. 1935, pages 522-524. Describes English practice. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 16R/7. JLG + AWM (7b)

Prediction of Weld Performance. Nairne F. Ward. *Welding Journal,* N. Y., Vol. 14, Dec. 1935, pages 11-15. Proper design of weld has been neglected in the past and is most important for correct adjustment of thermal stresses, especially in aircraft welding. The use of welded models for testing performance of welded section is discussed as concerns models made with same material as prototype, geometrically similar rather than made with celluloid, bakelite or rubber sections which usually show instability at the joints. The tests on scaled model are described and shown in photos. WB (7b)

Spot Welding Problems. J. H. Zimmerman. *Welding Journal,* N. Y., Vol. 14, Dec. 1935, pages 20-25. Brief discussion of literature references on machines, electrodes, timing devices, etc. Use of Cu-W and Cu-Cd alloys for electrodes has made for progress in spot welders and new electrode mentioned using steel sheath to prevent mushrooming. Problems encountered by various investigators in obtaining good mechanical properties and in working with different materials of light gage are recounted. A review of problems under investigation at M. I. T. on spot welding of Alclad sheet is given. WB (7b)

Electrical Characteristics of the Welding Arc. S. C. Osborne. *Welding Journal,* N. Y., Vol. 14, Nov. 1935, pages 11-18. Discussion of the arcs from fundamental standpoint giving voltage distribution across the arc which is divided into 3 zones, terminal voltage drops across anode and cathode and the arc stream voltage. These 3 zones are taken up in detail along with a discussion of ionization in the arc and thermionic emission. WB (7b)

Oxy-Acetylene Cutting of Stainless Steels. W. J. Priestley. *Industry & Welding,* Vol. 7, Dec. 1935, page 64. Brief description of cutting with and without flux. Ha (7b)

Improved Fabrication of 18-8 Chromium Steels. Donald R. Pratt. *Welding Journal,* N. Y., Vol. 14, Dec. 1935, pages 16-19. Discussion of fabrication with Cb stabilized plate and rod. Ti and Cb are considered equally effective in plate in overcoming intergranular attack but Cb for welding rod does not burn out as readily as Ti and welds therefore have greater corrosion resistance due to larger stabilizer recovery. Cb is recommended for welding ordinary, unstabilized steels also because of counteracting effect of Cb on C pickup. Where it is necessary to cross welds the Cb bearing rod deposit is protected against heat effect of the crossing weld. Precautions in welding stabilized 18-8 are to use neutral flame with flux painted on rod or seam, the use of flux paint on underside of weld is recommended as preventing oxidation. The weld should not be puddled because of excessive loss of Cb from such procedure. Other precautions in welding technique are given. WB (7b)

Definitions of Welding and Soldering Materials of Aluminum (Ueber die Begriffe der Schweiss- und Lötstoffe des Aluminiums) L. Rostosky. *Autogene Metallbearbeitung,* Vol. 28, Dec. 15, 1935, pages 377-378. The terms used for essential characteristics of basic material, flux, welding rod, and solders are defined. Ha (7b)

Some Aspects of Welding in Aircraft Construction. J. Roosenschoon. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 443-448. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 19L/1. JLG (7b)

What are the Determining Factors in Selecting an Electric Arc Welding Installation? (Welche Faktoren sind bestimmend bei der Wahl einer Lichtbogen-Schweissanlage?) Röder. *Elektrowärme,* Vol. 5, Dec. 1935, pages 293-294. The welding machine, kind of electrodes, human factor and automatic processes are discussed as to their importance in economy. Ha (7b)

Bend Testing of Welds—A Summary. M. F. Sayre. *Welding Journal,* N. Y., Vol. 14, Dec. 1935, pages 1-10. The article summarizes the bend testing specifications now in use in various countries. The various tests are compared in tabular form, photos and diagrams illustrating methods of performance. A critical analysis of the fundamentals of bending of a weld is given as summarized from discussion in the literature. Relative advantages of different methods are pointed out and a bibliography of specifications and bend testing literature is appended. WB (7b)

Welding Galvanized Iron. V. L. Sage. *Industry & Welding,* Vol. 7, Dec. 1935, pages 20-21. Methods by the C arc and oxy-acetylene process without destroying the galvanized coat are briefly discussed. Ha (7b)

A General Purpose Meter for Resistance Welding. C. Stansbury. *Sheet Metal Industries,* Vol. 9, Nov. 1935, pages 717-719. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 16L/2. AWM (7b)

Practical Side of Resistance Welding. H. S. JEFFS. *Sheet Metal Industries*, Vol. 9, Apr. 1935, pages 231-233. From a paper read to the Institution of Welding Engineers in London. General discussion. See also *Metals & Alloys*, Vol. 6, June 1935, page MA 232R/8. AWM (7b)

Ignitron Timing of Resistance Welding. J. W. DAWSON. *Symposium on the Welding of Iron & Steel*, May 2 & 3, 1935, *Iron & Steel Institute*, Vol. 2, pages 55-66. Discusses equipment used for timing of spot and seam welding. Materials successfully welded with timed welding are listed. JLG (7b)

Arc Welding in Argon Gas. G. E. DOAN & WM. C. SCHULTE. *Electrical Engineering*, Vol. 54, Nov. 1935, pages 1144-1149. Experiments made in welding of pure Fe (carbonyl Fe) in controlled pure gas atmospheres had the following results for an arc in A atmosphere: Stable welding arcs cannot be maintained in A of 99.5% purity when the electrode is clean, unless the open circuit voltage is greater than 62 volts and the short-circuit current greater than 110 amp. In air or in impure A stable arcs form readily at voltages and currents far less than these minima. No crater is formed under the iron arc in A. This condition results in complete lack of penetration into the base metal, and thus renders welding impossible. The globules at the end of the electrode grow gradually to about ¼" in diam. and detach under no apparent force except that of gravitation, and no pinch effect is observed. The melting rates/kw.hr. in A and in air are approximately equal. The pure Fe welds in A showed 90% reduction of area and 30% elongation, while the respective figures for pure Fe welds in air were only 3.5 and 4. On the other hand, the tensile strength was 40,000 lbs./in.^{2} against 65,000 in air. Apparatus used and welding are described in full, a current of 180 amp. at 10 to 12 volts was used, which varied somewhat for welds made in air and with coated electrodes. The melting rate in A was 0.922 lb./kw.hr., which is similar to that in air, 0.895 lb. The arc is quieter than in air. The tests were made with d.c. and polarities reversed. Ha (7b)

A Study of Arc Temperatures by an Optical Method. C. G. SUITS. *Physics*, Vol. 6, Oct. 1935, pages 315-322. Arc temperatures are determined by calculation from data obtained for the velocity of sound waves passing through the arc. Sound wave becomes "visible" due to luminosity of high pressure region and can be photographed with high speed camera; a spark discharge in air provides the sound wave source. Examples of the photographed waves are shown. At 5500° K. the calculated error due to uncertainty in reading wave shape, calibration errors, motor speed (for rotating mirror of camera), etc., is ± 100°. The arc materials, Cu, cored projection C, NaCl-cored C, Al-cored C, W-cored C, 6 mm. W, 9.5 mm. W, W welding arc, coated Fe welding arc are tabulated as to temperature in °K., electron density and effective ionization potential. The temperatures have a spread from 4000°-7000° K. W welding arc temperature and coated Fe welding arc temperature are 6150° and 6020° K. respectively. In the latter the current density using 125 amps. varied between 94 and 405 amps./cm.^{2} and temperature fluctuated between 4400° and 7000° K. (by estimation) with an average temperature of 6000°. Type W-20, coated welding rod is represented as most stable arc in common use. Arc stability is affected most by small amount of vapor of low ionizing potential, which lowers arc temperature and decreases gradient; it also affects the current density. The low ionizing potential vapor is supplied by coating material of the welding rod. The absence of dissociation processes in monomolecular A gas is considered to be the cause for unsuccessful attempts to arc weld in pure A atmosphere (Doan & Schulte, *Physical Review*, Vol. 47, 1935, page 783). WB (7b)

Results Recently Achieved by Research on the Oxy-Acetylene Welding of Mild-Steel. L. C. PERCIVAL. *Symposium on the Welding of Iron & Steel*, May 2 & 3, 1935, *Iron & Steel Institute*, Vol. 2, pages 471-474. Cites results obtained with remarkable new welding rod, but does not tell what rod is. JLG (7b)

The Physical Properties of Electrode Coatings. J. H. PATTERSON. *Symposium on the Welding of Iron & Steel*, May 2 & 3, 1935, *Iron & Steel Institute*, Vol. 2, pages 453-462. Describes behavior of a rod when coated with different materials and then used as an electrode. JLG (7b)

Welded Pipe Lines in Hydro-electric and Other Schemes. D. ROSS. *Symposium on the Welding of Iron & Steel*, May 2 & 3, 1935, *Iron & Steel Institute*, Vol. 1, pages 289-298. Describes methods of making and joining large welded pipe in England. JLG (7b)

Apparatus for Automatic Arc-Welding. E. ROSENBERG. *Symposium on the Welding of Iron & Steel*, May 2 & 3, 1935, *Iron & Steel Institute*, Vol. 2, pages 155-159. Shows where automatic arc welding is applicable and then describes a machine used for this type of welding. JLG (7b)

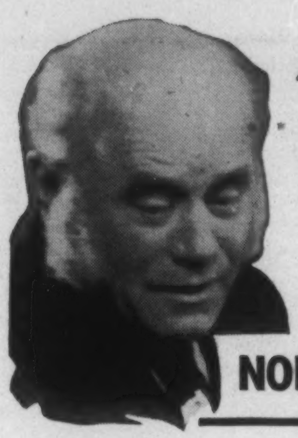
The Strength of Welded Connections. M. ROS & A. EICHINGER. *Symposium on the Welding of Iron & Steel*, May 2 & 3, 1935, *Iron & Steel Institute*, Vol. 2, pages 843-866. Gives and discusses data on static and dynamic strength of welded connections. JLG (7b)

The Varying Mechanical Quality of Fusion-arc and Oxy-acetylene Welds of Mild Steel Plate, and the Effect of Normalising Thereon. R. T. ROLFE. *Symposium on the Welding of Iron & Steel*, May 2 & 3, 1935, *Iron & Steel Institute*, Vol. 2, pages 539-552. Gives data on unwelded plate, plate welded by different methods, and plate normalized after welding. JLG (7b)

The Significance of Welding Tests. W. D. HALSEY. *Symposium on the Welding of Iron & Steel*, May 2 & 3, 1935, *Iron & Steel Institute*, Vol. 2, pages 803-809. Discussion of tests of welds and their significance. JLG (7b)

Some Notes on the Welding of Mine Haulage Gear. J. H. ANDREW & W. A. JOHNSON. *Symposium on the Welding of Iron & Steel*, May 2 & 3, 1935, *Iron & Steel Institute*, Vol. 1, pages 503-506. Describes manufacture and defects sometimes found in haulage gear. Wrought Fe is recommended for the manufacture of welded couplings and chain. JLG (7b)

Bridge Welding—A Review of the Literature. F. H. FRANKLAND. *Welding Journal*, N. Y., Vol. 14, Oct. 1935, appendix pages 1-16. An evaluation of the pertinent literature from 1926-1935 in the form of abstracts and a short introduction. WB (7b)



"IT'S EASY TO WELD MILD STEEL, LAD! MY PROBLEM IS DIFFERENT! I USE ALLOYS . . . FERROUS and NON-FERROUS and ALUMINUM"

"YOUR PROBLEM IS SIMPLE!

. . . NOW ALLOY and ALUMINUM WELDING IS DIFFERENT . . . . *glance at the records!*"

For welds in 18-8 stainless steels—
"STAINWELD A" gives
Tensile strength—85,000 to 95,000 lbs. per sq. in.; ductility—50% to 60% elongation in two inches; corrosion resistance equal to the plate; appearance—matches the plate.

For welds in 25-12 stainless steels—
"STAINWELD B" gives
Tensile strength—90,000 to 105,000 lbs. per sq. in.; ductility—40% elongation in two inches; corrosion resistance equal to the plate; can be polished equally as well as the plate.

For welds in high tensile steels—
"SHIELD-ARC 85" gives
Tensile strength—85,000 to 100,000 lbs. per sq. in.; ductility—20% or more elongation in two inches; fatigue resistance—45,000 lbs. per sq. in.

For welds in bronze, brass or copper—
"AERISWELD"
A shielded-arc type electrode that gives a strong deposit with the characteristics of true phosphor bronze.

For welds in aluminum—
"ALUMINWELD"
A 5% silicon aluminum alloy electrode for castings, sheets, shapes or extruded forms. Produces very dense, non-porous weld of high tensile strength.

Application of Welding for the Construction of Houses. M. Mopin. *Welder,* Vol. 7, Nov. 1935, pages 737-749. Problems of materials, semi-inoxidizable steels, arc welding methods and workmanship are discussed and examples given. Ha (7b)

1 **Repair of a 200 Ton Press (Reparation sur place d'une presse de 200 tonnes).** R. Meslier. *Bulletin de la Société des Ingénieurs Soudeurs,* Vol. 6, Aug.-Oct. 1935, pages 1873-1879. Lecture before the Société des Ingénieurs Soudeurs. Repair of the cast steel frame by means of bronze welding with reinforcement of repaired portion by means of an arc welded steel plate on each side of the frame. 2 cast Fe flywheels were also repaired. The broken portions were very numerous and bronze welding as well as arc welding was resorted to with various types of weld preparations and different kinds of added metals. Much difficulty was met with in repairing a fly wheel hub which was broken at the key groove. The repaired press has been in service for several months. FR (7b)

2 **Beautiful Welded Constructions (Les Belles Constructions Soudées).** R. Meslier. *Revue de la Soudure Autogène,* Vol. 25, Nov. 1935, pages 12-13. Examples described are cracking towers having 2.8 m. diameter and 23 m. height and weighing 60 tons built by French plant of Babcock and Wilcox. FR (7b)

3 **New Arc Welding Method (Ein neues Lichtbogen-Sonderschweissverfahren).** R. Hessler. *Die Wärme,* Vol. 58, Aug. 10, 1935, pages 511-519. A new welding method (German Patent No. 567 094) developed by the Krupp Works has been admitted by the German Welding Specifications on the Construction of Boilers. An austenitic Cr-Ni welding electrode is utilized for the pearlitic-ferritic boiler material of 0.3% C max. The nature of the welding method, microstructures, results on impact, tensile bending, forging, hardness, hydraulic and corrosion tests are reported. EF (7b)

Butt-Welding Avional (Duralumin) Electrically saldatura elettrica di testa dell'avional). M. Bosshard. *Alluminio,* Vol. 4, July-Aug. 1935, pages 219-221. 3 rods of duralumin, butt-welded electrically, were found to have the following properties: elastic limit 28.5 kg./mm.^{2}; tensile strength 37.2 kg./mm.^{2}; elongation (200 mm.) 1.7%; Brinell hardness 117 average. AWC (7b)

4 **Some Applications of Fusion Welding (Quelques Applications de la Soudure Autogène).** R. Granjon. *Bulletin de la Société des Ingénieurs Soudeurs,* Vol. 6, Aug.-Oct. 1935, pages 1838-1872. Lecture before the Société des Ingénieurs Soudeurs. Describes typical applications of fusion welding and with help of numerous illustrations shows the tremendous development of applications of welding process. FR (7b)

5 **The Welding of Chassis Frames.** H. S. Bavister. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 473-479. Describes welding in English plant by Sciaky spot-welding process. In this process the parts to be welded are held together by a pressure of about 20,000 lb./in.^{2} before and after the welding current and by a smaller pressure during the passage of the current. See also *Metals & Alloys,* Vol. 6, Dec. 1935, page MA 495L/5. JLG (7b)

6 **Shipbuilding by Welding.** Norman M. Hunter & H. W. Townshend. *Welding Journal,* British, Vol. 32, Nov. 1935, pages 346-348; *Electrical Review,* Vol. 117, Nov. 22, 1935, page 710. An account of construction of all-welded 245 foot tanker Moira and the application of welding to smaller trawlers. For large butted seams in plating 2 welders start in middle and work toward opposite ends of the plate. Welding in shipbuilding is important in overcoming fatigue failure of constantly vibrated parts, petroleum leaks in tankers through riveted seams, water seepage through riveted seams in deck and hull plating. Discussion shows welding eliminates punching, drilling, riveting and calking of ship shell. MS + WB (7b)

7 **When is Resistance Welding Applicable?** M. L. Eckman. *Machinery,* N. Y., Vol. 42, Jan. 1936, pages 297-301. Resistance welding in the form of spot, projection, seam, flash and butt welding is discussed from the point of view of what metals can be welded, where resistance welding is applicable and what must be the manufacturing conditions to make it applicable. Examples illustrate choice and economy of the various types of resistance welding. Ha (7b)

Welding High Pressure Steam Piping at U. S. Industrial Alcohol Co. Plant. J. A. Freiday. *Heating, Piping & Air Conditioning,* Vol. 7, Dec. 1935, pages 568-569. Review of reconstruction project involving acetylene welding of pipe 2" to 14" O. D. Discussion of welder qualification, testing of welds and stress relief. WB (7b)

8 **Welding in the Construction of the "Normandie."** W. Faerman. *Welder,* Vol. 7, Sept. 1935, pages 685-694. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 16L/5. Ha (7b)

Welding Repair Saves Bridge Badly Damaged by Smoke Corrosion. *Steel,* Vol. 98, Jan. 13, 1936, page 39. Corroded portions of stringers of bridge in Cleveland, O., were chipped away to expose sound metal. Lengths of steel plate were inserted between stringers, arc welded in place, and openings filled with weld-metal. Smoke plates were then welded to top and bottom to protect stringers from further corrosion. MS (7b)

9 **Air-Acetylene Method is Widely Used When Low Temperature Flame Is Needed.** *Steel,* Vol. 97, Oct. 7, 1935, pages 35-36. See "More Uses for Air-Acetylene Flame," *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 18L/10. MS (7b)

Studies Throw Light on Thermal Effect of Welding Structural Steel. *Railway Age,* Vol. 99, Dec. 21, 1935, pages 816-818. Tests indicate the presence of stresses but show that efficiency of metal is not seriously affected. CBJ (7b)

10 **Oxy-Acetylene and the Open Hearth.** *Iron & Steel of Canada,* Vol. 18, Dec. 1935, pages 88-90. The progress from 1901 to 1935 in the use of cutting and welding in the open hearth production of steel is reviewed. Ha (7b)

Porosity in Weld Metal. *Engineer,* Vol. 160, Dec. 13, 1935, pages 631-632. From the Technical Report for the years 1933-1934 of the British Engine, Boiler and Electrical Insurance Company, Limited. LFM (7b)

Automatic Welding of Food Compartments. H. Thomasson. *Canadian Machinery & Manufacturing,* Vol. 46, Aug. 1935, pages 37-38. Canadian Welder Section. Flexarc welder with a.c. of 100-125 amps. and superimposed high frequency current is used. The high frequency current carries the arc over the zero voltage part of the a.c. cycle. With this arrangement, a.c. is preferred to d.c. because of entire elimination of arc blow, higher welding speeds, sounder welds, more economical welding and less skillful operator required. Heavily coated $\frac{1}{8}$" electrodes are used which are principally gas-shielded and leave little slag. Heavy slag-producing coatings were found conducive to entrapped slag in the weld due to the low current employed; the slag gave trouble in enameling. Preparation for enameling consists in sand blasting welds and bosses, pickling the entire compartment followed by a black vitreous ground coat and two white coats, the last coat being acid resisting. New method reduced enameling rejects from 10% to less than 1%. WB (7b)

Gas Absorption by Welds (Etude de l'Absorption des Gaz par les Soudures). D. Seferian. *Revue de la Soudure Autogène,* Vol. 27, Nov. 1935, pages 4-10. O and N are present in steels as impurities. Welding which involves melting of the metal causes absorption of these 2 gases and ultimate properties of welds are affected thereby. Gas absorption is dependent upon numerous factors and chiefly upon welding method. With oxy-acetylene welding, there is little gas absorption, a maximum of 0.05% O and 0.02% N; hence, weld properties are little affected. This is due to the properties of oxy-acetylene flame. With arc welding, gas absorption is much more important and varies according to nature and thickness of electrode coating and electrical conditions of arc. In worst conditions following results are obtained: 0.30% O and 0.20 N (electrodes without coating and very long arc). In best conditions, absorption would be: 0.07% O (electrodes evolving H) and 0.03% N (thick coating). Following this, mechanical properties and particularly impact resistance of arc welds are considerably lowered by gas absorption. Author has also shown that N acts as a hardening element giving new compounds; properties of nitrided welds of very low C steels are much affected by heat treatment. FR (7b)

New Application of Atomic Hydrogen Welding (Une Application Nouvelle de la Soudure à Hydrogène Atomique). Maurice Lebrun. *Bulletin de la Société des Ingénieurs Soudeurs,* Vol. 6, Aug.-Oct. 1935, pages 1907-1913. Lecture before the Société des Ingénieurs Soudeurs. First gives principle of atomic H welding. Application described is the repair of a heavy bronze propeller wheel which had been worn out by erosion. Whereas end of propeller wings can be easily welded by means of torch, problem met with is quite different when erosion happens on thick part of the propeller near the hub. Atomic H welding has been resorted to with success in this case. It is emphasized that it will probably be possible to increase life of screws by depositing through welding harder and more corrosion resistant metal on parts where erosion always occurs. FR (7b)

Controlling Heat Effects in Welding. *Mechanical World & Engineering Record,* Vol. 98, Aug. 2, 1935, page 101. In general, heavy castings should be totally preheated before welding with the object of avoiding bad alignment. On plant repair work, this is sometimes next to impossible and interesting solutions to the problems then arising are given. WH (7b)

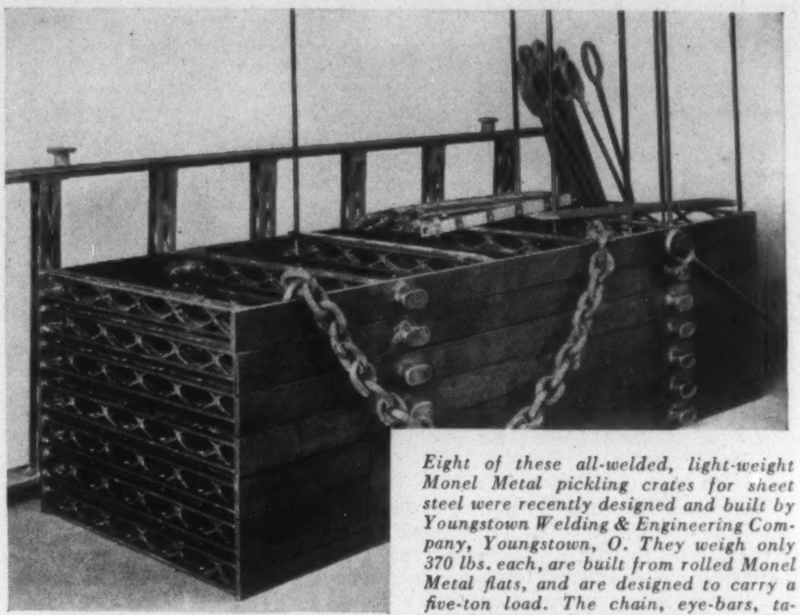
WELDED TRUSS DESIGN PICKLING CRATE SAVES 63% DEAD WEIGHT



Eight of these all-welded, light-weight Monel Metal pickling crates for sheet steel were recently designed and built by Youngstown Welding & Engineering Company, Youngstown, O. They weigh only 370 lbs. each, are built from rolled Monel Metal flats, and are designed to carry a five-ton load. The chain, eye-bars, tapered pins, and spacers are also rolled Monel Metal.

Novel Design Shows Advantages *of* MONEL METAL

THESE Monel Metal pickling crates each weigh 370 lbs. To carry their load (5 tons) a cast bronze crate weighs about 1,000 lbs. A clear saving here of 63%! Think what that means to your costs for power.

What makes possible this saving? Skillful design, of course. But design that takes full advantage of Monel Metal's strength and corrosion resistance, and *of welding!*

The No. 43 Silicon Monel Gas Welding Wire not only makes a good weld, but has resistance to corrosion equal to that of the parent metal.

Write for your FREE copy of "Equipment Designs for the Pickle House." It contains nothing that has not been found practical.

INCO WELDING RODS and FLUXES

For PURE NICKEL

Oxy-Acetylene . . . No. 41 Nickel Gas Welding Wire.
Metallic Arc . . . INCO Nickel Metallic Arc Welding Wire No. 31.
Carbon Arc . . . INCO Nickel Carbon Arc Welding Wire No. 21.

For MONEL METAL

Oxy-Acetylene . . . No. 40 Monel Gas Welding Wire. For flux see * below.
Oxy-Acetylene . . . No. 43 Silicon Monel Gas Welding Wire.
Metallic Arc . . . INCO Monel Metal Arc Welding Wire No. 130.
Carbon Arc . . . INCO Monel Metal Carbon Arc Welding Wire No. 20.

For INCONEL

Oxy-Acetylene . . . No. 42 Inconel Gas Welding Wire. For flux see † below.
Metallic Arc . . . Inconel Metallic Arc Welding Wire No. 32.

For NICKEL-CLAD STEEL (for welding of Nickel side)

Oxy-Acetylene . . . No. 41 Nickel Gas Welding Wire.
Metallic Arc . . . INCO Nickel Metallic Arc Welding Wire No. 35.
Carbon Arc . . . INCO Nickel Carbon Arc Welding Wire No. 21.

FLUXES

*INCO Gas Welding and Brazing Flux for Monel Metal.
†"Cromalloy" Gas Welding Flux is recommended for Inconel.
No flux is used for the gas welding of Pure Nickel or Nickel-Clad Steel.

INCO welding materials as listed can most conveniently be obtained through regular INCO distributors.

Monel Metal is a registered trade-mark applied to an alloy containing approximately two-thirds Nickel and one-third copper. Monel Metal is mined, smelted, refined, rolled and marketed solely by International Nickel.

MONEL METAL

Arc Welding Costs Reduced by Cross Field Principle. M. S. HANCOCK. *Iron Age,* Vol. 136, Dec. 5, 1935, pages 38-39, 106. Describes new cross field generator developed by Westinghouse Electric & Manufacturing Co. It hinges on 2 basic requirements; load regulation and no mutual inductance between exciting and differential field coils. Operating on cross field principle it can be preset for a given welding current which it maintains. Marked reduction in number of parts is also a feature of new design. VSP (7b)

Welding Machines for Assembling Automobile Parts. C. M. TAYLOR. *Machinery,* N. Y., Vol. 42, Nov. 1935, pages 175-176. Describes hydraulically operated machines. Ha (7b)

7c. Riveting

Riveted Pipe Lines. E. W. HOWELLS. *Structural Engineer,* Vol. 13, Oct. 1935, pages 404-411; *Mechanical World & Engineering Record,* Vol. 48, Nov. 1, 1935, pages 425-426, 428. Paper before the South Western Branch of the Institution of Structural Engineers at Torquay, Jan. 1935. The construction of large pipe lines in places remote from workshop facilities raises problems of transport and manufacture as well as of erection. Economy demands that plates be shipped flat which means fabrication near the site. The careful planning required by this type of work and the usefulness of riveting are fully considered and the erection of a large pipe line in India is described at great length. WH (7c)

High-Speed Riveting Fixtures. WM. C. BETZ. *Machinery,* N. Y., Vol. 42, Nov. 1935, pages 177-180. Multiple riveting machines able to give up to 1000 blows a minute are described. Ha (7c)

Special Riveting in Aeronautical Construction (Le rivettature speciali nelle costruzioni aeronautiche) P. DEL PONTE. *Alluminio,* Vol. 4, Nov.-Dec. 1935, pages 331-340. Expanding rivets are preferable in most cases because they can be applied more quickly and economically. AWC (7c)

Standard Specifications for Riveted Steel and Wrought-Iron Pipe. *American Society for Testing Materials,* A. S. T. M. Designation: A138-34; *American Standards Association,* A. S. A. No.: B36.8-1935, 3 pages. AHE (7c)

8. FINISHING

H. S. RAWDON, SECTION EDITOR

Finishing Vacuum Cleaner Parts. F. L. PRENTISS. *Iron Age,* Vol. 136, Nov. 28, 1935, pages 34-35, 84-85. Description of finishing method for Royal cleaners made by P. A. Geier Co. Permanent mold and sand castings of No. 12 Al alloy containing 95% Al are used. Polishing and buffing equipment consists of 30 lathes. Lubricated felt wheels are used for polishing Al, but no lubricant is used for polishing steel. Buffing wheels are made of fine-count muslin sheeting. Steel stampings are heavily plated with Cu, color buffed and Ni plated. VSP (8)

Finishing Methods Are Improved. *Steel,* Vol. 98, Jan. 6, 1936, pages 226, 327-329. Presents opinions of various authorities on accomplishments of the finishing industry in 1935. MS (8)

8a. Pickling

Reclaiming Disused Cans. C. C. DOWNIE. *Electrical Review,* Vol. 118, Feb. 14, 1936, pages 245-246. Describes an electrolytic method for cleaning paint and varnish cans. Principle is that gas bubbles formed at anode separate adhering paint skin from metal. Current sufficient to produce only desired amount of gas bubbles is used. Cans are placed upside down in open wooden cages with Cu connection for current to anode. Canister, suitably coated with graphite wash, serves as cathode. Electrolyte which will provide greatest amount of bubbles is most suitable. Generally, different concentrations of soda are most effective. Electrolyte is caused to flow through a filter. Voltage seldom exceeds 12 volts. Average can needs about 5 min. at a density of 200 amps. per can. MS (8a)

8c. Polishing & Grinding

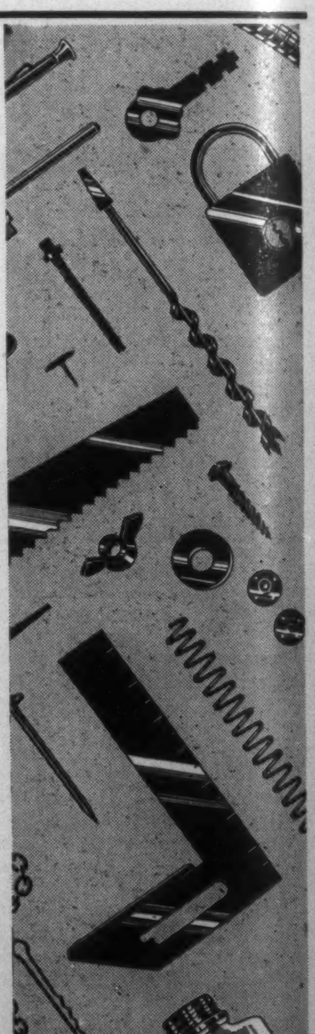
Safety Devices for Grinding and Polishing Machines (Sicherheitsmassnahmen an Schleif- und Poliermaschinen) BRAUER. *Oberflächentechnik,* Vol. 13, Jan. 21, 1936, pages 17-18. Special arrangements are shown for eliminating injuries to workmen on polishing and grinding machines with projecting shafts with interior thread; fingers of the worker were often caught in the thread. Ha (8c)

the JETAL process

a simple way to

BLACKEN

Iron and Steel



THE Jetal process colors iron and steel products at low temperature, by immersion, to a uniform and brilliant black. It is a complete finish in itself and will not chip, scale, peel or discolor. It replaces more involved and expensive black finishes and forms an excellent bond for subsequent finishes such as japan, lacquers, varnishes, enamels, etc., that require high temperatures.

■ 8d. Electroplating ■

The Electrodeposition of Chromium. E. A. OLLARD. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 46, May 17, 1935, pages 541-542; Vol. 47, July 26, 1935, pages 89-91; Aug. 23, 1935, pages 185-188. Chief uses of Cr are as a nontarnishable finish and a wear-resistant surface. Process is the same for both applications but more care is required for the thicker deposits necessary to withstand wear. The theory of electrodeposition is discussed together with mechanism of reaction, cathode reactions, formation of sulphate, its importance and its possible functions. The composition of the plating solution, methods of preparation and means of making sulphate additions are considered. The author does not favor additions of boric acid, chromic carbonate, borates, Cu salts, etc. which are sometimes recommended. His experimental data indicate that fluoride might be substituted for sulphate but no detailed research or commercial application of its use are yet known. A method of preparing and aging the solution when laboratory facilities are not available is suggested. The method of operating the solution is described. The importance of careful regulation of current density at the cathode, and the necessity for an adequate supply of current at the vat bus-bars are noted. Anodes, usually Pb or a Pb-Sb alloy, must be kept clean to insure good contact or unsatisfactory plating will result. The author considers the method of suspending the work one of the most important factors and one of the most difficult to describe. Heavy conductors are required as Cr-plating requires a high current density. Simple wiring, such as is used for other plating, is unsatisfactory as the heavy solution necessary tends to form insulating layers. For protecting portions of work not to be plated, soldering or the use of special jigs is suggested. Auxiliary anodes are sometimes used to advantage. The preliminary treatment varies but most material to be given a bright Cr-finish is Ni-plated and polished. It is then degreased by a trichlor-ethylene process and placed in the vat dry or else cleaned electrolytically, washed thoroughly in water of the temperature of the plating bath and put into the vat wet. The author prefers the latter method although both give good results. The subsequent treatment is outlined. Although the solution used is of a complex nature, it is not difficult to control as impurities, for the most part, do not play an important part in Cr-plating. The 3 factors to be controlled are the chromic acid or chromate content, the trivalent Cr, and the sulphate. Of these, only the sulphate must be determined by analysis. The other 2 factors, chromate content and trivalent Cr, may be determined from the specific gravity and conductivity of the solution. Methods for the adjustment of these factors are suggested. The control of the sulphate is the most difficult as it is not easy to determine whether the solution is deficient in sulphate or contains an excess. In the former case, addition of H_2SO_4 will correct the trouble, but in case of an excess, the trouble may be corrected by additions of Ba chromate, carbonate, hydroxide, or oxide. HBG (8d)

Some Peculiarities in Formation of Metallic Deposits (Quelques particularités de la formation de depôts métalliques) JEAN BILLITER. *Revue de Métallurgie,* Vol. 32, Nov. 1935, pages 518-521. At very low current densities, electrolytic deposition occurs only along grain boundaries of the base metal or along scratches present on them. There is no need for the space lattice dimensions of the deposited metal to be the same as in the base in order that the crystalline structure of the two shall be continuous. Forces of attraction have a pronounced influence here. The general opinion that these forces can extend to very short distances, of molecular order, is not consistent with the fact that the presence of an unoriented layer between the base and the oriented crystals of the deposit is easily visible under a microscope. When higher current densities are used, it happens occasionally that roughness originally produced on the surface deposited with low current density steadily persists. A theory is advanced that the film of electrolyte near the surface of the base which is impoverished by the current is of about the same thickness as the nuclei of deposited metal originally deposited and that it does not reproduce exactly all unevennesses of the surface. In this case, nuclei protruding through it closer to the normal electrolyte lead to an increasing precipitation in corresponding areas. The theory is supported by an experiment in which the current carried by two similar wires immersed in an electrolyte and electrically connected with a common anode was different depending on whether the wire, insulated on the outside, was pointing to the anode with its bare cross section or the end of it was inserted in an insulating plug so as to expose the same bare cross section. JDG (8d)

Mechanism of Brass Plating. C. B. F. YOUNG. *Steel,* Vol. 97, Dec. 23, 1935, pages 31, 34. In brass plating, it is necessary to have the normal cathode potentials of Cu and Zn equal or nearly so, in order to deposit the 2 metals simultaneously. Sulphate solutions are not commercially feasible because of the wide difference in potentials. Cyanide baths are practicable because of the close potentials of Cu and Zn in this solution. By forming double cyanides, potential of Cu is reduced much faster than that of Zn, until they become practically equal. This is especially true if excess cyanide is present. To deposit same composition of brass continuously, concentration of Cu, Zn, free cyanide, etc. must be maintained constant. Rate of solution of Cu and Zn at anode must equal rate of deposition at cathode. Increase of free cyanide content gives less Cu in brass, while decrease gives more Cu. Increasing current density increases Zn in alloy. Raising temperature increases Cu in alloy. pH of bath should be about 11, determined calorimetrically. If solution is too acid, NaOH or NH_4OH should be added. If it is too basic, dilute H_2SO_4 should be added. Best indicator is prepared by dissolving 0.6 gram thymolphthalein and 0.1 gram phenolphthalein in 300 cc. of 50% C_2H_5OH. Cathode and anode efficiencies should be as high as possible and equal to each other. All baths should be analyzed periodically to detect changes taking place and corrections made accordingly. Some Further Principles of Electrochemistry Applied to Electrodeposition. No. IV. Ostwald's Law of Dilution. SAMUEL FIELD. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 45, Nov. 16, 1934, pages 473-475. A parallel is drawn between the development of the science of electrochemistry and the development more than a century ago of the simple laws of chemical combination. Then, as now, general laws were based on studies of simple salts and, when necessary, amplified as more complicated reactions were studied. Using a simple electrolyte, NaCl, the author developed a formula for K, dissociation constant, which represents the ratio of the tendency of a molecular substance to ionize to the tendency of the ions to recombine. For weak electrolytes, such as acetic acid and monochloracetic acid, fairly constant values for K are obtained. The author states that this simple relation between degrees of dissociation at different states of dilution, known as Ostwald's Law of Dilution, is of general application for all electrolytes which do not freely dissociate in solutions of moderate dilution. For strong electrolytes the value of K is not constant which is attributed to other factors which, it is believed, have a more intimate bearing on electrodeposition than has the dissociation constant. HBG (8d)

Practical Plating. Deposition of Copper: II. Acid Copper Solution. E. A. OLLARD & J. W. PERRING. *Metal Industry,* London, Vol. 45, Nov. 2, 1934, pages 423-424; Nov. 30, 1934, pages 519-521. The acid solution containing $CuSO_4$ and H_2SO_4 is used when a thick deposit of Cu is desired. While it cannot be used for plating directly on Fe, steel, or certain other metals, such as Zn, it has the advantage over the cyanide solution in that in addition to plating it may be used for electrotyping and electroforming. When used in the latter types of work, precautions must be taken to move the objects during deposition and to agitate and circulate the solution. The theory underlying the operation of the solution is discussed together with the necessity for the addition of H_2SO_4 at intervals. The constituents of the solution, its method of preparation and certain precautions to be observed are discussed. "Addition agents," such as glue and phenol-sulphonic acid, are used when smooth, hard deposits with a fine grain structure are required. Phenol-sulphonic acid is considered to be the only satisfactory addition agent, and a method of preparing this compound is given. Results obtained indicate that phenol-sulphonic acid itself is not the active agent but rather an unknown decomposition product formed by electrolysis in the bath itself. It is emphasized that good Cu deposits are obtained only when suitable anodes are used. "Electrolytic" Cu, 99.9% purity is recommended. Small quantities of Fe and O are not considered harmful impurities, but As, Sb, Bi and Ag are considered detrimental and should not be present in excess of 0.01%. The physical properties of the anode are also important. The author suggests anodes that have been melted and rolled as hard as possible with proper annealing and pickling between passes. He recommends, however, an extruded anode that has recently come on the market. The method of operating the solution is discussed together with the results of using "hot" and "cold" solutions. Control of the solution is not difficult and may be done by determining the density and acidity of the solution. The effect of impurities in the solution, possible sources of these impurities, and method used for their removal are also considered. HBG (8d)

The Deposition of Zinc Cadmium Alloys from Alkaline Cyanide Solutions. LESLIE WRIGHT & J. RILEY. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 45, Nov. 16, 1934, pages 471-473. See *Metals & Alloys,* Vol. 6, July 1935, page MA 288R/5. HBG (8d)

Barrel Plating Technique. E. J. DOBBS. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 47, July 12, 1935, pages 41-42. Paper before Electrodepositors' Technical Society, June 12, 1935. Types of barrels used are (1) perforated containers for the articles to be plated placed in the tank containing the solution, (2) self-contained barrel and vat, not perforated, and (3) combination of types (1) and (2). The types of barrels, methods of operation and materials of construction are discussed. The conditions of deposition in barrel-plating are compared with the conditions in still plating and the necessary subsequent treatment is indicated. HBG (8d)

Air Conditioning of Lacquer and Plating Rooms. A. W. KNECHT. *Monthly Review American Electroplaters' Society,* Vol. 22, Nov. 1935, pages 22-32. Advantages of air conditioning are; fewer rejections, improved work with no increase in workmen's time, better morale and less time lost by respiratory diseases. Operations in the lacquer room are hampered on humid days by "blushing" of lacquer films before they dry. A conditioned atmosphere prevents blushing by keeping moisture content at a low value. Conditioning also removes all dust particles and thus eliminates another lacquer room problem. The air conditioning system itself is considered as follows:—(1) quality of the air, (2) distribution of the conditioned air. Under (1) are considered changes in the heat and moisture content and methods of accomplishing these changes. Under (2) are the unit and central types of distributing systems. The unit type consists of a number of small conditioning systems whereas the central type employs one conditioning system and the conditioned air is distributed. The cost of installing air conditioning in a lacquer room 75 x 20 feet, with 10 spray booths (other conditions are specified) is estimated at $22,000. Operating cost is estimated at $2.90/hr. for Carrene refrigerant and $2.15/hr. for the silical gel system. GBH (8d)

Mechanism of Chromium Deposition from the Chromic Acid Bath. CHARLES KASPER. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 47, Sept. 27, 1935, pages 327-330; Oct. 11, 1935, pages 375-377. Slightly condensed from *Bureau of Standards Journal of Research,* Vol. 14, June 1935, pages 693-709. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 22L/4. HBG (8d)

Electroplating Industry Keeps Pace with Modernization Movement. C. W. YERGER. *Steel,* Vol. 98, Jan. 27, 1936, page 54. The recent developments in electroplating have tended to eliminate the human factor and to obtain more uniform and better plating throughout. Bright Ni and bright Zn deposits have been developed and production has been increased and improved by use of higher current densities. Bright Ni deposit needs no buffing and can be plated directly with Cr. Most marked improvement to bright Ni finish has been use of Co-Ni alloy. MS (8d)

Non-poisonous Plating Solutions (Ungiftige galvanische Bäder) K. ASSMANN. *Chemiker-Zeitung,* Vol. 59, Nov. 6, 1935, pages 904-905. Most commercial plating solutions are poisonous, and there are several advantages in having non-poisonous solutions. For Ag plating a solution containing KI, AgI, HI and gelatine and for Cu plating KI, CuI, HCl and gelatine can be used. They have good conductivity and produce fine grained deposits with good adherence. Some AgI solutions have been used commercially. Solutions of AgCNS, NaCNS and CuCNS, NH_4CNS, Na_2SO_3 have also been tried. Deposits from these baths have a fine grain and better polishing properties than those from cyanide baths. A solution suitable for undercoating on steel contains $CuSO_4$, sodium oxalate, Na_2SO_4 and $B(OH)_3$. $Ag(CS(NH_2)_3)NO_3$ has been tried, but cannot be used with high current density. No non-poisonous brass solutions have been found. Cd can be plated from $CdSO_4$ with organic addition reagents, but it has poor throwing power and coarse-grain deposits are produced. Acid Zn and Sn baths are satisfactory. Attempts are being made to develop a Cr solution without chromic acid. CEM (8d)

Concentrated Copper Cyanide Plating Baths. L. C. PAN. *Paper, Electrochemical Society,* Oct. 1935, pages 243-253. Describes experiments performed to determine optimum concentrations of Cu free cyanide, and carbonate. The following formula is offered as best so far: Cu cyanide 12, NaCN 14.1, Na_2CO_3 10.4 ozs./gal. Temperature 22° C., current density 18.5 amps./ft.^{2} Cathode efficiency is 95%, anode efficiency 75.5%. Throwing power is 47.4% and rate of deposition is 2.25 g./amp. hr. The corresponding figures for an acid Cu solution are 9 to 10% and 1.16 g./amp. hr. See also *Metals & Alloys,* Vol. 6, Nov. 1935, page MA 454L/10. GBH (8d)

Six Years of Observation of Chromium in a Job Shop. WILLIAM A. VIGNOS. *Platers' Guide,* Vol. 32, Jan. 1936, pages 11-14. The deposition of Ni subcoat should be controlled as regards Cl, acidity, and metal content, with temperature and current density having some bearing on the type of deposits. Arrangement of the work in regard to the anodes is important. The coating produced during the first few seconds determines the character of the final Cr plate. The effects of size and shape of anodes, SO_4 content, trivalent Cr, and of Fe are briefly touched upon. WHB (8d)

Nickel and Chromium Plating of Zinc Objects (Das Vernickel und Verchromen von Zinkgegenständen). FRITZ SCHÄFER. *Metallwaren Industrie & Galvano Technik,* Vol. 33, Nov. 1, 1935, pages 459-460. White coloration on Zn surfaces can be removed with a mixture of 1000 cc. H_2O, 15 cc. chromic acid, 5 cc. H_2SO_4 in 3-5 min. Cr or Ni plating prevent this defect *a priori.* The treatment of Zn surface prior to electro-plating is fully described. Cu or preferably brass intermediary layers are indispensable in the case of Ni plating. Zn die-castings are preferably polished in a drum containing steel balls and polishing agents. EF (8d)

Some Further Principles of Electrochemistry Applied to Electrodeposition. V. Mixed Electrolytes. VI. Coulometers. SAMUEL FIELD. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 46, Jan. 18, 1935, pages 103-104; Feb. 15, 1935, pages 199-200. There is seldom only one conducting constituent in an electroplating bath. Generally a supplementary conducting compound is added to reduce electrical resistance and facilitate current flow. In this article changes in conductance by the mixing of 2 electrolytes, various combinations of $CuSO_4$ and H_2SO_4, are considered. It is pointed out that in electroplating practice advantage is taken of the fact that the addition of a good conducting substance to the bath not only increases the total conductance but also reduces the degree of dissociation of the poorly conducting substance present e.g., the addition of Na_2SO_4 to a solution for Ni-plating Zn-base die castings. One advantage of this is that the preliminary coating with Cu in a cyanide bath is eliminated. Throwing power is usually increased by a scarcity of metal ions e.g., the almost negligibly small proportion of Cu ions in Cu cyanide. Measurement of current used in electrodeposition is important but since the accuracy of ammeters or other forms of electromagnetic instruments may be questioned, a method is desired that (1) accurately records steady currents and (2) accurately averages a varying current. Certain types of electrolytic cells will do this. The essential requirements of coulometers are (1) the translation of every coulomb into the desired product; (2) the products must be capable of quantitative collection and measurement; and (3) if the products are solid, they should have a large equivalent mass. Other relevant conditions are (a) ease of manipulation, (b) relative costs, and (c) availability of sufficiently pure materials. The mechanism of gas, Cu and Ag coulometers are discussed with their advantages and limitations. The Ag coulometer is used for the most accurate work. Other coulometers that have practical applications use Pb and Hg. HBG (8d)

Methods of Suspension in Electrodeposition Practice. C. F. J. FRANCIS-CARTER & B. J. R. EVANS. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 46, Feb. 1, 1935, pages 153-154. Abstract of paper read before the Electrodepositors' Technical Society on Jan. 16, 1935. See *Metals & Alloys,* Vol. 6, June 1935, page MA 238R/1. HBG (8d)

Cr and Cd Plating (Chromage et Cadmiage). J. LOISEAU. *Métaux,* Vol. 9, Oct. 1934, pages 560-564. Cr plating solution consists of 300 g./l. chromic acid and 3 g./l. H_2SO_4, temperature maintained at 45° C. with a current density of 10 amps./dm.^{2} The ratio H_2SO_4 to CrO_3 is maintained at 1 to 100. The bright deposit is obtained with a ratio $\frac{1}{100}$ to $\frac{1}{200}$ $\frac{H_2SO_4}{CrO_3}$. The Cd bath consists of Cd cyanide and Na cyanide to produce the combined cyanide, $Cd(CN)_2NaCN$ and free cyanide. Cd content varies between 15-20 g./l. and free cyanide 10 to 30 g./l. The following proportions are used: NaCN 49 g./l.; $Cd(CN)_2$ 41 g./l.; and NaOH 20 g./l. with a current density of 1.5 to 2 amps./dm.^{2} GTM (8d)

Cathode Film Produced During Electrolysis of Solutions Containing CrO_4 (Der Kathodenfilm bei der Elektrolyse CrO_4-haltiger Lösungen). ERICH MÜLLER & WILHELM STEIN. *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 172, Mar. 1935, pages 348-352. An invisible film preventing reduction during electrolysis of oxidation products, forms on Au and Pt upon cathodic polarization in a bichromate solution, on less noble metals, such as Ag, Cu, brass, upon mere immersion in the solution. Its existence is demonstrated by the fact that it prevents proper adhesion of Ag electrodeposited from a cyanide solution on a metal which has been treated as above. Its composition seems to differ with the method of production, and it is dissolved by various acids at different rates. ORS (8d)

8e. Metallic Coatings other than Electroplating

Recent Calorizing Research. J. B. NEALEY. *Heat Treating & Forging,* Vol. 21, Oct. 1935, pages 483-484. **Calorizing Process Is Improved.** *Iron Age,* Vol. 136, Oct. 24, 1935, pages 28-29. Improved process of calorizing eliminates flaking as the coating produced is a very tough Fe-Al alloy. So effective is the process that steel may be completely converted to Fe-Al alloy if desired. MS + VSP (8e)

Aluminum Coated Iron (Feuerveraluminiertes Eisen). A. VON ZEERLEDER. *Aluminium,* Vol. 17, Sept. 1935, pages 483-487. Iron can be coated with Al by immersion in molten Al similarly to hot-galvanizing or hot-tinning. The various methods of coating Fe with Al (calorizing, alumetizing, welded-on coatings) still offer some difficulties and require absolutely clean surfaces. They are, therefore, economically not quite satisfactory. "Hot-aluminating," i.e. hot-dipping, is practiced today mainly according to the patents of Dellgren (Swiss patent 1665061), of C. G. Fink, and of Rodriguez (French patent 760,374). The metal is treated by metal chlorides or hot gases before it is immersed in molten Al. Hot-aluminated wire has been successfully employed in place of Cr-Ni wires as heating elements up to 900° C. As Al is non-toxic the material can be used safely in the food industry (canning). Such material can also be treated like Al by the eloxal process (anodic oxidation) which still further improves the corrosion resistance. Ha (8e)

Here and There with Metallizing. L. E. KUNKLER. *Metallizer,* Vol. 3, Aug. 15, 1935, page 10. Metal spraying in the architectural stone industry is practicable and is being used extensively by a few companies. Stone and concrete novelties, such as book ends, plaques, etc., can be sprayed with bronze or other metals to give the appearance of solid metal. Decorative metal spraying is being successfully applied to building fronts. BWG (8e)

The Manufacture of Aluminum Plate. HAROLD SILMAN. *Metal Industry,* London, Vol. 46, Mar. 29, 1935, page 358. Brief description of different methods of producing Al plated sheet Fe. These are the dipping process, the calorizing process, spraying and rolling processes. Relative advantages and shortcomings of the different processes are indicated. HBG (8e)

Hardness of Sprayed Metal Coatings (Die Härte gespritzter Metallschichten). KESSNER & EVERTS. *Zeitschrift für Metallkunde,* Vol. 27, May 1935, pages 104-107; abstract, *Metal Industry,* London, Vol. 46, June 28, 1935, page 700. Discusses sprayed coatings of Zn, steel, V2A, Cu, Al, and Monel, with emphasis on the first three. The effects of temperature on the base material, working distance of sprayer, gas pressure, character of spray atmosphere, feeding speed, and rate of coverage upon structure, scratch hardness, and Brinell number are discussed and optimum conditions given. GD + HBG (8e)

8f. Non-Metallic Coatings

Coloring Metals (Über Metallfärbungen) H. KRAUSE. *Metallwirtschaft,* Vol. 14, Dec. 13, 1935, pages 1015-1017. Cd can be colored black by dipping in cold solution of 60 g. $KClO_3$, 35-40 g. $Cu(NO_3)_2$, 1 l. H_2O, brushing, redipping, rinsing, drying, and polishing. Another solution for the same purpose contains 30 g. $Cu(NO_3)_2$, 2.5 g. $KMnO_4$, 1 l. H_2O, used at 60°-80° C. Cd is colored brown in a solution containing 160 g. $KMnO_4$, 60-250 g. $Cd(NO_3)_2$, 1 l. H_2O. Cu and Cu alloys are colored brown by repeated dipping in a hot solution of 5 g. $KMnO_4$, 50 g. $CuSO_4$, 1 l. H_2O, and brushing. Addition of a little $FeSO_4$ produces a greenish color. A solution of 50-60 g. $KClO_3$, 100-125 g. $CuSO_4$ or $Cu(NO_3)_2$, 1 l. H_2O colors Cu and its alloys a reddish brown. Various shades can be produced by addition of Ni or Fe salts. Cu is colored red by dipping in molten KNO_2 or $NaNO_2$. A violet color is obtained by adding 1% $KMnO_4$. Fe is colored black by a mixture of molten $NaNO_3$ and $NaNO_2$. Addition of 5-25% NaOH produces a flat black. For some purposes it is better to color Fe in a solution of 1.5% g. NaOH, 25-50 g. $NaNO_3$, 5 g. tannic acid, 1 l. H_2O at about 160°. Al is colored gray by electrolysis in a bath of 100 g. As_2O_3, 30 g. Na_2CO_3, 10 g. KCN, 1 l. H_2O, and black by 10-20 g. $(NH_4)_2MoO_4$, 5-15 g. NH_4Cl, 1 l. H_2O. The latter can also be used for Zn, Fe, Pb, Sn and Cd. CEM (8f)

Metal Coloring with Molybdate Solutions (Metallfärbungen mit Molybdatlösungen) H. KRAUSE. *Metallwaren Industrie & Galvano Technik,* Vol. 33, May 15, 1935, pages 209-212. See *Metals & Alloys,* Vol. 6, Sept. 1935, page MA 365R/7. EF (8f)

Coloring of Iron in Sodium Hydroxide Containing Oxidizing Agents (Färbung von Eisen in Natronlauge mit Oxydationsmitteln) H. KRAUSE. *Metallwaren Industrie & Galvano Technik,* Vol. 33, Sept. 15, 1935, pages 393-394; Oct. 15, 1935, pages 433-435. See *Metals & Alloys,* Vol. 6, Nov. 1935, page MA 455R/6. EF (8f)

Cement Lining of Large Diameter Mains in Place by a Centrifugal Machine ELSON T. KILLAM. *Journal American Water Works Association,* Vol. 27 Aug. 1935, pages 1065-1072. Description of the cement lining of mains 48" diam. or larger by a traveling centrifugal machine. VVK (8f)

Concrete Coating for Pipe and the Wilson Machine. STERLING C. LINES. *Journal American Water Works Association,* Vol. 27, Dec. 1935, pages 1694-1698. Description of the Wilson machine which extrudes a cement coating on the pipe. VVK (8f)

Conditions Governing the Formation of Highly Insulating Anodic Layers on Aluminum. J. E. LILIENFELD, J. K. NIEH & S. GOLDMAN. *Paper, Electrochemical Society,* Oct. 1935, pages 67-80. Authors' abstract: "It is shown that for any given electrolyte there is a critical current density at the Al anode above which formation of the anode takes place. The value of this critical current density, called by us the minimum formation current, is independent of the voltage to which the anode has already been formed. Experiments were made with pure alkali hydroxide forming solutions, and also with alkali hydroxide solutions in which the hydroxyl ion concentrations were reduced by the addition of weak acids. In every case it was found that the hydroxyl ion concentration of the forming solution was the most important factor controlling the magnitude of the formation current.—." GBH (8f)

Rustproofing and Paint Adherence Technique Analyzed. F. P. SPRUANCE. *S. A. E. Journal,* Vol. 37, Dec. 1935, pages 459-464. Porosity of paint surface is favorable to electrolytic action of moisture on exposed pinhole areas. Therefore the problem of rustproofing in automotive field resolves itself into the prevention of the failure of the paint film. Since porosity of the organic coatings is unavoidable the only method of preventing the destruction of the decorative finish by peeling and cracking due to rusting of the underlying metal, is to treat the metal surface. A good rustproofing coating must possess ductility equal to that of the steel base and proper surface to give good bond with the paint. Various treatments of the steel surface are described; dioxidine treatment being one of the earlier processes for removing all traces of grease, oil, etc., from the steel and coating the surface with a mixture of phosphoric acid and oil solvent. Bonderite, spray-bonderite, electro-granodine, zinc granodine, oxalate, cromodine are the other methods. The Bonderite method is a dip in boiling Mn dihydrogen phosphate containing a small amount of Cu phosphate. It is not itself considered a rust preventer but allows greater thickness of paint film because of deposited phosphate coating on etched metal surface. In the spray-bonderite method, the most recent method of protection, sprays of the Zn phosphate are used after a degreasing cleansing of steel surface; after rinsing in plain water, a hot water-chromic acid rinse is used. Electrogranodine method gives a coating of Zn phosphate by electrolysis with a.c. in Zn phosphate electrolyte. After the steel has been degreased and cleaned, formation of coating takes place in about 3 min. with 35 amps./ft.^{2} of surface. This coating is claimed to be as rust resistant as electrolytically deposited Zn but with the advantage over the latter in that it allows perfect adherence to the paint. Zn granodine method consists of first plating thin Cd or Zn coating then forming Cd or Zn phosphate on the surface of this plate by a process as yet not described. This protective coating has greater ductility than is possible with other methods cited. Oxalate process which uses oxalic acid and Fe oxalate, gives non-resistant non-adherent, brittle coating. Cromodine method may be carried out by dipping or spraying, the solutions used being as yet unspecified, but the product is claimed to be a thin film of Fe chromate. Photographs are shown of test panels of different paints on steel samples prepared by the various methods. WB (8f)

Imitation Wood Finishes on Metal. *Steel,* Vol. 98, Jan. 20, 1936, pages 32-33. In the application, sandblasting is recommended as most suitable surface preparation. Fairly heavy baking synthetic is best for primer. For better grade finishes, baked primer should be sandpapered prior to application of color coat. Latter matches wood finish desired. Grain is then transferred from Zn plates in flat-bed lithographic presses. Heavy coating of clear lacquer is then applied and rubbed to a uniformly dull finish. In many cases it is advisable to fabricate parts first and then apply entire finish a rubber hand roller being used to apply graining ink. All materials except grain are applied by spraying. MS (8f)

Applying Cement Mortar Lining to Existing Mains in England. THOMAS H. WIGGIN. *Journal American Water Works Association,* Vol. 27, Aug. 1935, pages 1073-1081. Description of the Tate process of cement lining water mains *in situ* using Portland cement, Ferro-crete and Ciment-Fondu. VVK (8f)

Notes on Application of Sheet Iron Acid Resisting Enamel. W. H. NOBLE. *Enamelist,* Vol. 13, Dec. 1935, pages 8-9, 49. Acid-resisting enamel can be applied over either the wet or dry regular enamel, according to which procedure lends itself best to production methods. Preparation and methods of applying this enamel are described. Ha (8f)

Preservative Coatings for Structural Materials, Report of A.S.T.M. Committee D-1. ALLEN ROGERS, Chairman. *Proceedings American Society for Testing Materials,* Vol. 35, Part I, 1935, pages 314-323. Progress report on specifications and of subcommittees. Of particular interest is the "**Statement on Principles of Testing Paints and Combinations of Paints on Steel Panels**" pages 322-323. VVK (8f)

Common Defects in the Vitreous Enamelling of Sheet Iron, C.R.C.A. Steel and Cast Iron. C. P. STONE. *Sheet Metal Industries,* Vol. 9, Oct. 1935, pages 633-636, 642. A paper presented at the second annual conference of the Institute of Vitreous Enamelers in London on Sept. 28. A comprehensive survey of the author's findings in practical enameling. AWM (8f)

Electron Diffraction Examination of Protective Films Deposited on Magnesium and Magnesium Alloys by the R A F Dichromate Process. H. G. HOPKINS. *Metal Industry,* London, Vol. 47, Sept. 13, 1935, page 273. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 22R/1. HBG (8f)

Rust Protection (Zeitgemässes vom Rostschutz) H. HEBBERLING. *Oberflächentechnik,* Vol. 12, Dec. 3, 1935, pages 281-282. Present views on ground coats for rust protective coatings on Fe are discussed and methods of application described. Instead of pure red lead, a mixture of red lead and barites is used with a saving in both pigment and binder (linseed oil) without sacrifice in quality. Bonderizing, parkerizing, bitumen coats and their correct application are briefly reviewed. Ha (8f)

Buick Anodizes Pistons on Production Basis. *Iron Age,* Vol. 136, Nov. 7, 1935, pages 38-39. Describes use of process at plant of Buick Motor Co. which in effect is a "deplating" operation. Instead of depositing material on the Al alloy piston, electric current in bath is reversed so as to make the piston the anode. The surface metal is converted by anodic oxidation to a hard oxide, which increased the life of piston by increasing its wear-resistance. VSP (8f)

The Duraspray Rust-Proofing Process. *Engineering,* Vol. 140, Oct. 25, 1935, page 456. This process for coating steelwork *in situ* was developed by Messrs. Duraspray, Limited, London. It consists in applying a priming coat of special red lead paint and then, before this is dry, dry-spraying on finely-divided metallic powder. This powder is made up of specially-prepared Zn dust and a certain proportion of Al. A final coat of paint is applied. LFM (8f)

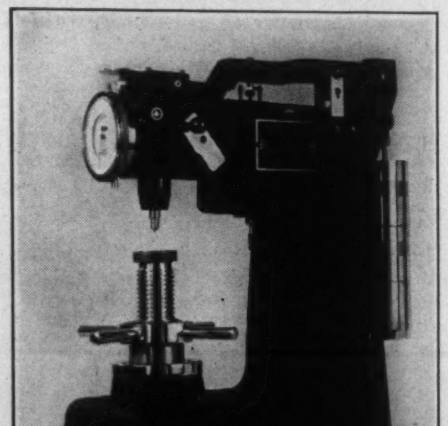
C. S. BARRETT, SECTION EDITOR

The Failure and Breakdown of Machinery. *Engineering,* Vol. 140, Oct. 25, 1935, pages 449-450. Editorial commenting on the recent Technical Report of the British Engine, Boiler and Electrical Insurance Company, Limited. The report considers failures due to such causes as the chemical embrittlement of boiler plates, the presence of intergranular cracks on rivets, and the introduction of welding. There seems at the present time to be a need for research on the transmission of stress-waves across the interface of welded materials. It would be helpful if fatigue tests were carried out with models of complete systems working under practical conditions. This would lead to information on the endurance limit of the machine regarded as a unit. It would be of interest to know under what circumstances the conditions of the Izod test are simulated in practice. LFM (9a)

X-Ray Exposure Charts for Steel. HERBERT R. ISENBURGER. *Transactions American Society for Metals,* Vol. 23, Sept. 1935, pages 614-620. With discussion before the New York Convention A.S.M. 1934. Previously abstracted from Preprint 22. See *Metals & Alloys,* Vol. 5, Nov. 1935, page MA 528. WLC (9a)



"ROCKWELL" HARDNESS TESTER

A shop tool so accurate and sensitive it has been adopted by research laboratories everywhere.

High Energy Carpenter Torsion Impact Testing Machine

What hardening temperature gives greatest toughness? Should I preheat slowly before hardening? Does soaking at the hardening heat affect toughness? Which shall I use—lead pot—electric—or gas furnace? How high shall I draw? How long? How is toughness affected by carbon percentage? Do cold drawn bars make as tough tools as hot rolled?

The new high energy Carpenter Torsion Impact Machine will give you the answers to these questions, together with much other vital information.

Have you investigated this recently developed machine which utilizes the same principles as former machines, but which has available 50,000 ft-lb. at 1,000 r.p.m.—energy sufficient to test any known steel under usual testing conditions in specimen diameters up to 1" and even as high as 1⅜" diameter in many steels?

Engineering Radiography. V. E. Pullin. G. Bell and Sons, Ltd., London, 1934. (American Agents: Engineers Book Shop, New York). Cloth, 8¼ x 11¼ inches, 136 pages. Price $16.00.

England's leading exponent of radiography has condensed into this book his experience in the interpretation of radiographs. It is written for engineers unfamiliar with the subject and consists mainly of a "de luxe" printing of some 180 radiographs. The apparatus for radiography is given a brief mention, the technique of X-ray and γ-ray radiography is discussed concisely, and a few paragraphs accompany each series of films pointing out the types of defects that are shown; but the radiographs themselves fill the most of the book and are the principal reason for its very high cost. In many cases there are sketches of the radiographed pieces and photographs of the pieces after sectioning to reveal the internal defects. The radiographs are not classified according to types of defects but according to the specimen studied: for example, the author presents in 12 pages a "Detailed Examination of Part of an Engine Column (Box Type) Steel Casting" following it with a study of another casting of the same kind that covers 20 pages and still a third that takes 10 additional pages. With such lavish printing of the films he naturally illustrates each of the defects commonly found in steel castings many times—in fact many more times than is necessary. The quality of the reproductions is excellent and cannot be criticized except by those who prefer to see them appear as "negatives" resembling the original films instead of "positives" resembling prints from the films as is done throughout this book.

The book, however, is not conveniently arranged. The numbering of prints is not consecutive throughout the book; there is no index; instead of a few sentences of explanatory matter under each photograph, the explanations are frequently to be found several pages removed from the photograph; and in the whole book there is not a single literature reference. There is little or no attempt to correlate casting practice or welding practice with the defects produced, and there is no mention of radiography of non-ferrous and non-metallic materials. C. S. Barrett (9a) -B-

Specifications for Radiographic Examinations of Steel Castings for Piping Service. Herbert R. Isenburger. *Heating, Piping & Air Conditioning,* Vol. 7, Nov. 1935, page 530. Proposed specifications given as practiced by author. WB (9a)

Examinations of Welded Seams by X-rays, Status 1935 (Untersuchungen von Schweissnähten mit Röntgenstrahlen, Stand 1935) H. Halberstadt. *Elektrowärme,* Vol. 5, Dec. 1935, pages 304-306. Curves and tables are given to determine time of exposure, distance between source of X-rays and film, and thickness of material to be irradiated. Present methods of exposing and evaluating plates are briefly described. Ha (9a)

Examination of Surface Quality of Parts for Motor Vehicles (Untersuchung der Oberflächengüte von Kraftfahrzeugteilen) A. Wallichs & G. Depiereux. *Automobiltechnische Zeitschrift,* Vol. 39, Jan. 10, 1936, pages 1-8. Determination of surface quality is of importance in parts produced in large quantities and for exchange; an objective method is necessary. Instruments have been developed which operate either optically or mechanically; the latter are sometimes connected with an acoustic apparatus which makes the surface irregularities audible (Harrison). The practical applications for manufacturing processes are discussed. 10 references. Ha (9a)

■ 9b. Physical & Mechanical Testing ■

W. A. TUCKER, SECTION EDITOR

The Relation Between the Tension Static and Dynamic Tests. H. C. Mann. *Proceedings American Society for Testing Materials,* Vol. 35, Part II, 1935, pages 323-335, discussion pages 336-340. Attempts to correlate impact test results have been unsuccessful due to the varying interpretations of data obtained from a wide variety of shapes and sizes of notched specimens. From the use of a tension form of specimen which could be tested under both static and dynamic conditions, data have been obtained which have led to the discovery of a correlation between these two types of tests. This correlation involves consideration of the fact that a material in its initial state possesses a certain amount of inherent potential energy which, during the process of deformation, is apparently converted to kinetic energy and manifested as increased elastic strength. The data indicate that the mechanism of the process of deformation and rupture is essentially the same in both static and dynamic tests. The work involved in producing deformation depends on force, time, and space, and therefore must be independent of the magnitude of the applied force. The rate of deformation for maximum energy conversion is dependent on the composition and condition of the material. The dynamic properties of a material are dependent on three major factors; volume (as determined from the length of uniform least diameter or section), velocity of the applied force, and material condition (also influenced by temperature). The present available types of impact machines are too limited with respect to velocity for determining the complete dynamic properties of materials. While the data presented concern only the tension form of test specimen, it appears entirely reasonable to assume that the theory is equally applicable to other types as well. To obtain a complete knowledge of the dynamic properties of materials, impact tests should be conducted through a range of velocities of a magnitude sufficient definitely to reveal material embrittlement. The combination of such data with that of the static test, should make possible definite predictions as to the subsequent behavior of materials under known service conditions. VVK (9b)

Notched Bar Impact Tests. G. Burns. *Metallurgist,* Dec. 1935, pages 86-88. Results of comparative Izod notched bar impact tests on Ni and Ni-Cr-Mo steels using the B.S.I. standard 10 x 10 mm. test piece and the sub-standards 10 x 5 mm. and 5 x 5 mm. test pieces showed that any attempt to convert the impact figures obtained with the smaller test pieces into the standard impact figure is subject to the possibility of a large error of the order of ± ⅓ and that, as the values given by the smaller test pieces do not rise in the same proportion as those given by the standard test piece, the subsidiary standard test pieces will not discriminate so well between tough and brittle materials as will the British standard test piece. Work on the German proposed sub-standard test piece is also reviewed. VVK (9b)

Effect of Test Conditions on Shrinkage Determination (Einfluss der Versuchsbedingungen auf das Schwindmass) O. Bauer & H. Sieglerschmidt. *Metallwirtschaft,* Vol. 14, Oct. 25, 1935, pages 854-858. The usual method for determining shrinkage was used, but the length and width of the test pieces, the rate of pouring, and the temperature of the mold were varied. The alloy was 16% Sb, .21% graphite, balance Pb. With equal width the short pieces shrank more than the long ones. With equal length the narrow pieces shrank more than the wide ones. With slow pouring rate the size of the test piece had less influence on the shrinkage than with fast pouring rate. At 20° C. mold temperature the quickly poured test pieces had higher shrinkage than the slowly poured ones, but at 130° the conditions were reversed. The results are explained by the effect of the test conditions on the average temperature of the metal in the mold which controls the shrinkage. Photomicrographs of slowly cooled and quenched test pieces showed segregation in the upper part of the mold, especially in the slowly cooled pieces. CEM (9b)

Hardness Testing of Light Metals and Alloys. R. L. Templin. *Proceedings American Society for Testing Materials,* Vol. 35, Part II, 1935, pages 283-304; *Metal Industry,* London, Vol. 47, Aug. 16, 1935, pages 157-160. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 25L/3. HBG (9b)

Survey of the Testing Methods for the Determination of the Mechanical Strength of Aluminum Castings (Allgemeiner Ueberblick über die Untersuchungsmethoden zur Bestimmung der Festigkeitseigenschaften von Aluminium-Gussstücken) A. von Zeerleder. *Aluminium,* Vol. 17, Nov. 1935, pages 570-574. The manner in which a specimen has been prepared for a tensile or hardness test is of utmost importance. Separately cast and cast-on specimens or taken from the casting are discussed and the tests described. The best results are obtained with horizontal casting. Ha (9b)

Special Apparatus Used for Testing Aluminium Alloys. E. John Pike. *Metallurgia,* Vol. 13, Dec. 1935, pages 35-37. Briefly describes machines for testing impact fatigue, bearing and frictional properties, and a rotating fatigue test for determining effects of casting and heat-treatment stresses in castings having abrupt changes in section. A study to determine stresses by X-ray diffraction is mentioned. Properties of some Al alloys are given to show the superiority of alloys produced by the author's firm. JLG (9b)

Measuring Surface Finishes. W. G. Myers. *Product Engineering,* Vol. 7, Jan. 1936, page 5. Size and shape of surface irregularities are measured with the "profilograph" in which a diamond tracer point moves on the surface and deflects the path of a light ray by a mirror attached to the point. Photographic records can be made. Ha (9b)

Impact Abrasion Hardness of Molded Boron Carbide and of Some Cemented Tungsten and Tantalum Carbide. L. H. Milligan & R. R. Ridgway. *Paper, Electrochemical Society,* Oct. 1935, pages 453-458. The test for hardness is performed by subjecting the polished surface of a specimen to a standardized pressure blasting, using a constant abrasive at a constant pressure. The depth of the depression produced is a measure of the hardness. In this paper it was found that for "impact abrasion" resistance molded boron carbide is approximately 15 times as suitable as crystals of boron carbide. GBH (9b)

Mechanical Testing with Small and Large Test Pieces. *Metal Treatment,* Vol. 1, Autumn 1935, pages 133-134. Annotated translation of paper by P. Chevenard in Bulletin de la Société d'Encouragement pour l'Industrie nationale, Vol. 134, 1935. JCC (9b)

Methods of Testing, Report of Committee E-1. W. H. Fulweiler, Chairman. *Proceedings American Society for Testing Materials,* Vol. 35, Part I, 1935, pages 486-496. Progress report. **Supplement A (1935) to A.S.T.M. Manual on Presentation of Data. Presenting ± Limits of Uncertainty of an Observed Average,** pages 1411-1417. This supplement discusses the problem of presenting ± limits to indicate the uncertainty of the average of a number of observations obtained under the same essential conditions, and suggests a form of presentation for use in A.S.T.M. reports and publications where needed. **Supplement B (1935) to A.S.T.M. Manual on Presentation of Data. "Control Chart" Method of Analysis and Presentation of Data.** Pages 1418-1437. This supplement gives formulas and tables useful in applying the "control chart" method of analysis and presentation of quality data obtained from several samples. This method provides a criterion for detecting lack of statistical control of quality, which is often used for determining when observed variations in quality are greater than should be left to chance. VVK (9b)

The Effect of Cold Bending on the Elastic Properties of Heavy (3½ in. Thick) Steel Plates. C. H. Gibbons. *Proceedings American Society for Testing Materials,* Vol. 35, Part II, 1935, pages 275-282. This paper reports the results of a series of experiments in which test specimens were taken from various parts of a .17% C and a .27% C plate both in the cold-bent condition and in the stress-relieved condition and stress-strain determinations were carefully made on each specimen. No conclusions are drawn as the paper is intended only as a presentation of little-known data on a complex and controversial subject. VVK (9b)

A Method of Determining the Strength of Weld Metal Within a Welded Joint. *Engineer,* Vol. 160, Dec. 20, 1935, page 657. From the Technical Report for the years 1933-1934 of the British Engine, Boiler and Electrical Insurance Company, Limited. LFM (9b)

Method of Determining Distribution of Stress in Fusion-Welded Joints. *Engineer,* Vol. 160, Oct. 11, 1935, page 385. From the Technical Report for the years 1933-1934 of the British Engine, Boiler and Electrical Insurance Company, Limited. LFM (9b)

Significance of Tests on Automobile Body Sheet. J. C. Arrowsmith. *Metal Treatment,* Vol. 1, Autumn 1935, pages 117-120. Sheet steel used for die pressing inevitably lacks uniformity since it is made from "rimming" steel. Variations in composition between casts and in grain size cause varying amounts of hardening during cold rolling and influence degree of age-hardening. Apart from difficulty of obtaining representative samples, no test really measures properties which decide drawing behaviour. Tensile tests for elongation, yield point, and ultimate strength are favored as providing the most useful information. JCC (9b)

Pendulum Hardness Testing (Über Pendelhärteprüfung) W. Schmidt. *Fortschritte, der Mineralogie, Kristallographie & Petrographie,* Vol. 19, Sect. I, 1935, page 62. The reproducibility of pendulum hardness values is stressed and its utilization for mineralogical studies is recommended. EF (9b)

Hardness Conversion Chart. Clarence J. Schilling. *Steel,* Vol. 97, Sept. 23, 1935, sup. Chart for mutual conversion of hardness numbers according to Brinell, Rockwell B, Rockwell C, and scleroscope scales. Last pertains only to C, C-V, and Cr-Ni steels. MS (9b)

Bolts under Static and Impact Loads. *Engineering,* Vol. 140, July 26, 1935, pages 102-103. From a paper by H. L. Whittemore, G. W. Nusbaum & E. O. Seaquist entitled "Impact and Static Tensile Properties of Bolts" and published in the *Journal of Research of the National Bureau of Standards,* Feb. 1935. See *Metals & Alloys,* Vol. 6, July 1935, page MA 290R/2. LFM (9b)

Standardization of Resiliency Tests (Normalizacion de Ensayos-Resiliencia) J. Castells Ruiz. *Metalurgia y Construccion Mecanica,* Vol. 1, Nov. 1935, pages 13-14. Principle of the Charpy test and the machine used for it are briefly described. Ha (9b)

Optical Surface Testing of Metals, in Particular with Regard to Their Corrosion (Optische Oberflächenprüfung von Metallen, besonders hinsichtlich ihrer Korrosion) A. Karsten. *Werkstoffe & Korrosion,* Vol. 10, Dec. 10, 1935, pages 61-62. An instrument is described for determining the quality or changes of surfaces by lacquers, corrosion, paints, etc. The microscopic arrangement is rugged enough to be used in manufacturing processes by unskilled hands. Ha (9b)

A Bend Tester for Vacuum Tube Wires. W. J. Farmer. *Bell Laboratories Record,* Vol. 14, Dec. 1935, pages 139-142. A method to subject fine wires of 0.003″ to 0.125″ dia. and from 1 to 5 cm. long as used in radio tubes to bending tests is described. Ha (9b)

Stresses in Overstrained Material. *Engineer,* Vol. 160, Sept. 13, 1935, pages 270-271; *Engineering,* Vol. 140, Sept. 13, 1935, pages 281, 291-292. From a report of the Committee appointed by Section G in 1928 and read by J. G. Docherty before the British Association for the Advancement of Science, Sept. 1935. LFM (9b)

A New Method and Machine for Dynamic Hardness Testing. W. M. Patterson. *Proceedings American Society for Testing Materials,* Vol. 35, Part II, 1935, pages 305-322. Includes discussion. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 24R/9. (9b)

Testing of Engineering Materials. *Journal of Commerce, Shipbuilding & Engineering Edition,* Oct. 31, 1935, page 1. A discussion on the value of alternative methods of static tensile or bending tests as against fatigue tests for assessing the value of engineering materials with special reference to the testing of crane hooks, eyebolts and chain slings. JWD (9b)

180,000 kg. Compound Lever Universal Testing Machine. *Mechanical World & Engineering Record,* Vol. 98, Nov. 8, 1935, pages 449-450. The machine described tests up to 177 tons and has a space capacity of 20 x 23 x 6 ft. It is an advance in the construction of universal machines of the vertical type. WH (9b)

The "David Brown" Disc Testing Machine. *Mechanical World & Engineering Record,* Vol. 48, Dec. 6, 1935, page 550. Two discs in contact can be revolved at different speeds. The length of the line of contact can also be varied. The machine is used to determine the frictional properties of different materials and to compare the qualities of different oils under gear-tooth loading conditions. WH (9b)

Unusual Test Determines Impact Strength of Welds. *Machine Design,* Vol. 7, Dec. 1935, page 25. Describes simple but unusual means of determining the impact values of welds in the construction of oil barges. A welded 12″ box section is placed on railroad ties spaced 8 ft. apart. Then a 180 lb. weight is dropped 100 times starting from a height of 3 ft. and finishing at 75 ft. WH (9b)

New Methods for Measuring Mechanical Stresses at Higher Frequencies. A. Bloch. *Nature,* Vol. 136, Aug. 10, 1935, page 223. 2 new methods are devised for measuring stresses in impact problems or during vibrations. (1) A C coating is laid on an insulating varnish applied to the surface under examination. Changes in resistance of the C coat, as it is stressed by the underlying surface, are followed in an oscillograph. (2) A Rochelle salt crystal is cemented to the surface and the piezoelectric voltages induced by stretching or compressing it are measured in an oscillograph. CSB (9b)

Stresses in the Tyres of Locomotive Wheels. *Engineering,* Vol. 140, Oct. 25, 1935, pages 439-440. Comments on a paper by E. G. Coker & M. Salvadori issued for written discussion by the members of the Institution of Mechanical Engineers. LFM (9b)

The Testing of Engineering Materials. H. J. Gough & W. J. Clenshaw. *Transactions Institute of Marine Engineers,* Vol. 47, Nov. 1935, pages 241-267; discussion, pages 257-276. The lecture discusses certain aspects of the testing of engineering materials many of which have special interest in connection with marine engineering. Some mention is made of the method of test employed but attention is primarily given to current or recently completed researches carried out at the National Physical Laboratory. In each aspect covered, reference is made to some practical problems which appear to require further research. The subjects dealt with are: high tensile structural steels, testing of materials at high temperatures, welded joints, lubricants and bearing metals, failure of metals under complex stress distributions, fatigue and corrosion fatigue of metals, cracking of boiler plates, materials for high temperature service, contact corrosion under stress, lifting gear components and failures in service. WH (9b)

■ 9c. Fatigue Testing ■

H. F. MOORE, SECTION EDITOR

The abstracts appearing under this heading are prepared in cooperation with the A.S.T.M. Research Committee on Fatigue of Metals.

Fatigue Testing at the National Physical Laboratory. H. J. Gough & W. J. Clenshaw. *Mechanical World & Engineering Record,* Vol. 48, Dec. 13, 1935, pages 575-577. Describes and illustrates 2 fatigue testing machines developed at the N.P.L. for (1) testing wires and (2) testing plates. WH (9c)

Cracking of Boiler Plates. H. J. Gough & W. J. Clenshaw. *Mechanical World & Engineering Record,* Vol. 48, Dec. 6, 1935, pages 551-553. Efforts have been made to simulate boiler conditions in testing specimens but without convincing success. The latest development is a special machine for fatigue stressing a specimen while immersed in boiling solutions. WH (9c)

Fatigue Strength of Aluminum Alloys (Die Ermüdungsfestigkeit der Aluminium-Legierungen) R. Irmann. *Aluminium,* Vol. 17. Dec. 1935, pages 638-643. The usual determination of fatigue strength is made in the machine by Schenck with polished specimens. The fatigue strength is influenced by the structure of the alloy (heterogeneous or homogeneous), by the manufacturing process (casting, rolling, heat treatment), and by notch effects (due to casting skin, inclusions, segregations, oxidation). These effects are discussed individually for different Al alloys, and shown in diagrams and photographs of structures. The fatigue strength is defined as that load in kg./mm.^{2} which the material will stand under an alternating load of 100 x 10^6 alternations for Al wrought alloys, and 20 x 10^6 alternations for Al cast alloys. Ha (9c)

Some Aspects of the Fatigue Properties of Patented Steel Wires. II. Note on the Effect of Low-temperature Heat Treatment. E. T. Gill & R. Goodacre. *Engineering,* Vol. 140, Sept. 27, 1935, pages 342-343; *Iron & Coal Trades Review,* Vol. 131, Sept. 20, 1935, pages 426-428. From a paper read before the Iron & Steel Institute, Sept. 1935. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 72R/4. LFM + Ha (9c)

The Rotating-wire Arc Fatigue Machine for Testing Small-diameter Wire. J. N. Kenyon. *Proceedings American Society for Testing Materials,* Vol. 35, Part II, 1935, pages 156-166; *Mechanical World & Engineering Record,* Vol. 98, Aug. 8, 1935, pages 125-127. See *Metals & Alloys,* Vol. 6, Aug. 1935, page MA 331L/5. WH (9c)

High-speed Fatigue Tests of Several Ferrous and Non-ferrous Metals at Low Temperatures. W. D. Boone & H. B. Wishart. *Proceedings American Society for Testing Materials,* Vol. 35, Part II, 1935, pages 147-155. Includes discussion. See *Metals & Alloys,* Vol. 6, Aug. 1935, page MA 331L/3. (9c)

9d. Magnetic Testing

L. REID, SECTION EDITOR

On the Magnetization of Single Crystals of Nickel at Various Temperatures. Kotaro Honda, Hakar Masumoto & Yuki Shirakawa. *Science Reports Tohoku Imperial University*, Vol. 24, Nov. 1935, pages 391-410. Magnetization of single crystals of Ni were measured by the ballistic method at temperatures from —252° to 370°. At ordinary temperatures the magnetization in the direction of the (111) axis was found to rise rapidly, then more slowly as the field increased until saturation values were reached. Magnetization curves in the direction of the (110) and (100) axes were similar to those of the (111) curves but saturation values were not reached at low temperatures even in a field of 1000 oersteds. At absolute zero the saturation value of magnetization of Ni was estimated to be 523 gausses. BWG (9d)

Electro-Magnetic Tests for Work-Hardening Steel Wires. T. F. Wall. *Engineer*, Vol. 160, Sept. 13, 1935, pages 260-263. Two electro-magnetic test methods were used in this investigation of steel wires after having been in service as mine winding and haulage ropes. The ballistic magneto-striction method consists in magnetizing the wire to a known value of H and then applying a load to the wire. Induction increase due to the load is measured by the throw on a ballistic galvanometer. The tests show that the effect of work-hardening results in a relatively smaller response to large stresses. The second test method records the speed of travel and the rate of decay of a surge of stress in the wire. The method provides means for the observation of work hardening and overstrain and also measures Young's modulus in wires which are distorted in such a way that it is difficult to apply the method of longitudinal vibrations and impossible to apply the direct method of static elongation. For this test the wire must be approximately 100 ft. long. The wire is passed through 3 or 4 solenoids at equal distances along the wire and at the center of each solenoid is placed a search coil. A blow is struck at the end of the wire which is clamped at one end, to start a surge stress which then travels along the wire. As each solenoid is passed, the surge gives rise to an e. m. f. in the corresponding search coil, and this is recorded on the oscillogram. The surge decays in magnitude as it travels the length of the wire and the induced e.m.f. decays accordingly. A simple method for the calculation of Young's modulus by this means is given. A table is given comparing the figures obtained for Young's modulus by means of the traveling surge test and by the longitudinal vibration test. The materials tested include normal hard-drawn steel, annealed steel of the same composition, steel wire from a new haulage rope and steel of the same composition from a used rope, hard-drawn Armco wire, annealed Armco wire, hard-drawn pure-Ni wire and annealed pure-Ni wire. The figures show that except in the case of hard-drawn Armco wire, the value of Young's modulus measured by the traveling surge method is less than the value obtained by the longitudinal vibration test. The value for hard-drawn Ni wire is 15% greater than the value for the Ni wire in the annealed condition. Reproduction of typical oscillograms are given. LFM (9d)

9e. Spectrography

Spectrographic Determination of Impurities in Commercial Cadmium. Frances W. Lamb. *Proceedings American Society for Testing Materials*, Vol. 35, Part II, 1935, pages 71-78. A spectrographic procedure for analysis of the impurities in commercial Cd is described and illustrated by reproductions of typical analyses. A description of a simple method developed for preparing and impregnating graphite electrodes with solutions, which insures the obtaining of uniform exposures with minimum blackening of the background of the spectra, is given. The application of this procedure to the analysis of Cd-base alloys and to Cd compounds is pointed out. VVK (9e)

Quantitative Analysis of Non-Ferrous Alloys by Spectroscopic Methods. R. A. Wolfe. *Proceedings American Society for Testing Materials*, Vol. 35, Part II, 1935, pages 87-92, discussion pages 93-98. The spectrographic analysis of non-ferrous alloys, using the method devised by Duffendack, Wolfe & Smith (*Industrial & Engineering Chemistry*, Vol. 5, July 15, 1932) is described. Details are given on the determination of Al in Ni-alloys, Mg in Zn-alloys, Ba in Ni-alloys and Cr in Ni. Excitation conditions are fixed, a working curve from known standards is prepared in which is plotted the ratio of the logarithms of the relative intensities of the spectral lines against the known composition, the spectrum of the unknown sample is photographed and the logarithm of the relative intensities of the selected lines determined and then applied to the working curve giving the desired percentage. The advantages of the method are; known standards are only used once in making the working curve; analyses using only one exposure can be made; no assumptions are necessary as to the validity of the reciprocity law, the introduction of intermittency effect, or in determining exact lengths of photographed lines; the accuracy is ± 5%; a large number of elements can be analyzed at each exposure and at least 10 exposures made on a single photographic plate; analyses have been made in about 15 minutes which can probably be shortened. VVK (9e)

The Purification of Graphite Electrodes for Spectrochemical Analysis. G. W. Standen & L. Kovach, Jr. *Proceedings American Society for Testing Materials*, Vol. 35, Part II, 1935, pages 79-85, discussion page 86. The removal of metallic impurities from graphite electrodes is accomplished by the heat-treatment method or the solvent-purification method. In the heat-treatment method, electrodes which have been given a brief preliminary solvent treatment are maintained in a furnace at 1000° C. for 23 hrs. During this period the electrodes are initially saturated with dry ammonia and finally, maintained in an atmosphere of chlorine for the remainder of the run. In the solvent-purification method, the graphite electrodes are subjected to a series of solvent treatments which effectively leach out the various impurities with the exception of B and Si. Final traces of impurities are removed by burning the electrodes in an electric arc following either of the purification procedures. VVK (9e)

10. METALLOGRAPHY

J. S. MARSH, SECTION EDITOR

Relative Changes in Dimensions of Metal Wire on Annealing (Variazione relative nelle dimenzione di fili metallici per ricottura). V. Montoro. *La Metallurgia Italiana*, Vol. 27, July 1935, pages 504-507. Annealing was shown by Scarpa (*Alluminio*, 1932) to cause contraction in previously hardened Al. Several other metals have been found to have this same property, as shown by their increase in sp. gr. after annealing. Thus Al shows 0.07% increase in sp. gr.; Cu 0.00; Ni 0.19%; Fe (Armco) 0.20%; and harmonic steel 0.25% increase. The sp. gr. were measured at 27.5° C. using a pycnometer. The change in length during annealing was also measured by enclosing the wire in a steel die having a groove of the same length as the wire used (175 mm.), and provided at the end with a vernier arrangement to measure the change in length. Al and Ni show practically no change in length; Fe and brass show a slight contraction; steel expands. The changes in diam. and vol. are calculated using the equation

$$(1)\quad \frac{D}{D_o} = \sqrt{\frac{d_o}{d}} \times \frac{L_o}{L}$$

D_o and D being the diam. of the wire before and after annealing; L_o and L the relative lengths; or $(2)\quad \frac{\Delta d}{d} = -\frac{\Delta V}{V} = -\left(\frac{\Delta L}{L} + 2\frac{\Delta D}{D}\right)$

Below is a resume of the results:

			Annealing temp. °C.	Change in sp. gr.	Change in length	Change in diam. formula (2)
Al (commercial)	4	mm.	250° C.	$+0.07.10^{-2}$	$-0.01.10^{-2}$	$-0.03.10^{-2}$
	3.36	mm.	250° C.	$+0.06.10^{-2}$	-0.00	$-0.03.10^{-2}$
Cu (electrolytic)	3.36	mm.	450° C.	0.00	$+0.02.10^{-2}$	——
Fe (Armco)	2	mm.	650° C.	$+0.21.10^{-2}$	$-0.57.10^{-2}$	$+0.18.10^{-2}$
Ni (electrolytic)	3	mm.	700° C.	$+0.14.10^{-2}$	0.00	$-0.007.10^{-2}$
Brass (comm.)	4	mm.	480° C.	$+0.15.10^{-2}$	$-0.07.10^{-2}$	$-0.04.10^{-2}$
Steel (1.06% C)	3.5	mm.	650° C.	$+0.11.10^{-2}$	$+0.06.10^{-2}$	$-0.08.10^{-2}$

Change of Transformation Point and Microstructure of Chromium Steels Due to Cooling Conditions. T. Murakami & H. Kishimoto. *Tetsu-to-Hagane*, Vol. 20, Nov. 1934, pages 788-797. In Japanese. Utilizing magnetic analysis of specimens of less than 27.8% Cr and 1.55% C, the change of the transformation point due to the cooling conditions was studied, and several diagrams showing composition range in which the transformation is lowered and its change due to the cooling conditions were proposed. The microstructure of these specimens and its change due to the cooling conditions were examined, and structural diagrams showing the relation between the composition of specimens and the microstructures in 4 cases cooled from 900° and 1100° C. in furnace and in air, respectively, were constructed. Based on these diagrams the effects of C and Cr contents in specimens, the cooling rate and the maximum heating temperature on the microstructure were explained. By examining the microstructure of several specimens which were carburized and cooled under several conditions the effect of C on the microstructure was studied, and the correctness of the structural diagrams obtained above was confirmed. Small X-ray Apparatus for Fine Structure Investigations (Ein Kleinröntgenapparat für Feinstrukturuntersuchung). W. E. Schmid. *Zeitschrift für technische Physik*, Vol. 16, Apr. 1935, pages 115-119. Description of an X-ray apparatus for crystallographic investigations. Its main features are: a special water-cooled tube, 500 watts maximum, which can be operated at 30, 37, or 45 kv, with controllable tube amperage; 3 windows combined with complete electron shielding of the glass wall, permitting making 3 simultaneous exposures 35 mm. from the target; optical and acoustical signals and automatic cut-outs eliminating danger to inexperienced operators; great adaptability to various working conditions permitting convenient working in combination with X-ray goniometers, temperature chambers, and on specimens subjected to mechanical stress. See also *Metals & Alloys*, Vol. 5, Aug. 1934, page MA 412. ORS (10)

Perfect Ternary Solid Solutions. Harry Seltz. *Journal of Chemical Physics*, Vol. 3, Aug. 1935, pages 503-505. Equations are developed for calculating the solidus and liquidus surfaces with tie lines for ternary systems showing complete solid solubility, based on the assumption that both liquid and solid solution are perfect. The forms of the liquidus and solidus isotherms predicted by these equations are considered for a hypothetical example. The ternary system Au-Cu-Ni is shown to deviate markedly from ideal behavior at low mol fractions of Au, even though the Cu-Ni system is practically ideal in its binary behavior. It is pointed out, however, that the Au-Ni system shows partial miscibility in the solid state and that the Au-Cu system though completely miscible in the solid state, shows a minimum in its phase diagram. Amorphous Condition on Polished Surfaces of Metal. G. B. Hogaboom. *Monthly Review, American Electroplaters' Society*, Vol. 22, June 1935, pages 47-49. In answer to a discussion of existence or non-existence of an amorphous layer at metal surfaces, quotations are given from papers by Desch, Hopkins, Portevin and Cymboliste, and Lee, which were presented at a meeting of the Faraday Society, London, March 29, 1935. All conclude that the amorphous or Beilby layer exists on polished metal surfaces. GBH (10)

The Metallurgy of Low Carbon Metallic Arc Weld Metals. J. C. Hodge. *Welder*, Vol. 7, July 1935, pages 624-640; Aug. 1935, pages 654-660. The changes in chemical composition of the metal occurring during the arc transfer, the characteristic macro- and microstructures arising from the abnormal conditions in melting and casting of metal, and the variations in mechanical properties throughout a range of temperatures as affected by the before mentioned changes and by subsequent heat treatment are described, using a welding rod of 0.21% C, 0.22% Mn, 0.125% Ni. Experiments and literature are discussed. Ha (10)

Iron-Tantalum Binary System (Zur Kenntnis des Zweistoffsystems Eisen-Tantal). Werner Jellinghaus. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 223, Aug. 9, 1935, pages 362-364. 6 alloys were prepared with Ta metal and carbonyl Fe to 6, 10, 15, 25, 50 and 75% Ta by weight. These were prepared by sintering and then melting down in alundum crucible. Investigation of microstructure, magnetic saturation, fine structure, and diagram is reported for a range of Ta from 0 to 50 atomic %. In the 6% alloy the structure of the cooled ingots is homogeneous. When this is quenched in oil from 1200° C. there is a needle-like precipitation in the coarse-grained material. In the 10% alloy a fine network surrounds the primary grains and inside the grains there is a needle-like precipitation as in the 6% alloy. The 15% Ta has the same appearance as the 10% alloy. The max. solubility of Ta in α Fe is at the eutectic temperature between 6 and 10% Ta. The γ loop extends to a max. at about 4.25% Ta. At 25% Ta the Fe rich solid solution in dendrite form is embedded in a lamelar eutectic. The Ta content of the eutectic was determined to be between 25 and 50% Ta. The study was extended by investigating the fine structure by means of Debye-Scherrer photograms. At 15% Ta, lines other than those of Fe begin to appear, the Ta lines becoming stronger as the Ta is increased and at 75% Ta the Fe lines have disappeared. For the lattice a = 4.81 A.U. and c/a = 1.64 A.U. Calculation of elementary cell showed 158.0x 10^{-24} cm.^{3} which indicates FeTa. FeTa melts at 1700° C. WB (10)

Diffusion of Hydrogen and of Deuterium in Palladium. I (Über die Diffusion von Wasserstoff und von Deuterium in Palladium. I). W. Jost & A. Widmann. *Zeitschrift für physikalische Chemie,* Abt. B, Vol. 29, Aug. 1935, pages 247-255. The diffusion constant of H in Pd determined under conditions excluding the effect of boundary reactions has been found to be: (in 10^{-5} cm.^{2} sec.$^{-1}$, at 192.5° C., —1.21; at 248.5° C., —2.43; at 302.5° C., —3.95; that of D in Pd: (same unit) at 192.5° C., —0.97; at 302.5° C., —3.01. The values are in agreement with the theory within the limits of accuracy of these experiments. ORS (10)

Contributions to the "Electrolysis" of Solid Alloys (Versuche zur "Elektrolyse" fester Legierungen). W. Jost & R. Linke. *Zeitschrift für physikalische Chemie,* Abt. B, Vol. 29, June 1935, pages 127-132. When an electric current passes through a glowing wire of an Au-Pd alloy, a transfer of Au and Pd takes place. Change of composition at the ends of the wire was determined by X-rays. The "transference number" of Pd is about 10^{-11} at 900° C. Contrary to theoretical expectations Au is transferred towards the anode, as has been also observed with Au-Pb alloys by Seith & Etzold (*Zeitschrift für Elektrochemie,* Vol. 40, 1934, pages 829-832). No theoretical interpretation of the results is attempted for lack of sufficient data. ORS (10)

Effect of Metals of the Iron Group on Precipitation Hardening of Aluminum Alloys of High Purity (Ueber den Einfluss von Metallen der Eisengruppe auf die Aushärtung von Aluminiumlegierungen hoher Reinheit). W. Koch & F. W. Nothing. *Aluminium,* Vol. 17, Oct. 1935, pages 535-546. The effect of the metals Fe, Cu, Ni, and Mo on precipitation hardening was investigated in an Al-Cu alloy with 4% Cu by taking time-hardness curves at room temperature, at 135°, and at 200° C. The results can be summarized briefly as follows (test series with Fe): Quench-hardness as well as precipitation hardness at all temperatures decreases with increasing Fe content. This is ascribed to the fact that Cu is bound by the addition of Fe and thus taken out of the solid solution. A ternary component is hereby formed, Cu_2FeAl_2. Test series with Co: Co is practically insoluble in the Al-Cu alloy with 4% Cu in solid state. It occurs as an intermetallic compound of probable composition Co_2Al_9. At 525° C. the quenching hardness shows an increase probably partly due to the hardening action of the precipitations and partly to an increase of the concentration of the solid solution by removal of Al on account of the binary compound. Additions of 0.1-0.2% Co impede the precipitations at first strongly, the increase in precipitation hardness being about the same as that of the quench hardness. Test series Ni: The view of Bingham that Al-Cu-Ni alloys do not show precipitation hardening to any pronounced degree (*Journal Institute of Metals,* 1926, page 137) does not seem to be correct, as tests with Ni up to 2% show a slowly decreasing precipitation hardening with increasing Ni content; the decrease has a certain relation to the quench hardness. The reason for the decrease is seen in the decrease of the amount of Cu available for precipitation of the solid solution, and in the formation of the ternary compound. Test series Mo: The deciding influence in Al-Cu-Mo alloys is exerted by compound $MoAl_3$ or $AlMo_4$. The increasing hardness after quenching from 360° C. is due to the hardening effect of the precipitated components. Curves show precipitation hardness maxima at different temperatures which are parallel among themselves and also to the curve of quench hardness at 525° C., except for very small additions; from this it can be concluded that both quench hardness and aging and precipitation hardness are subjected in principle to the same effects, which view was also corroborated by examination of the structures. For the ternary alloys it can be stated in general that precipitation hardening is proportional to the Cu dissolved in the solid solution. According to whether compounds are Cu-free or Cu-containing, quench and precipitation hardness will be more or less affected. 16 references. Ha (10)

Iron-cobalt-tin System (Das System Eisen-Kobalt-Zinn). W. Köster & W. Geller. *Archiv für das Eisenhüttenwesen,* Vol. 8, June 1935, pages 557-560. The ternary diagram of the system Fe-Co-Sn to 40% Sn is sketched. The boundaries of the solid phases were determined by measurements of the hardness, coercive force, loss of magnetism, and microstructure. An alloy with 19% Co and 5% Sn showed precipitation hardening. SE (10)

Isomorphism of the Ternary Compounds $Mg_3Zn_3Al_2$ and Mg_4CuAl_6 (Über die Isomorphie der ternären Verbindungen $Mg_3Zn_3Al_2$ und Mg_4CuAl_6). F. Laves, K. Löhberg & H. Witte. *Metallwirtschaft,* Vol. 14, Oct. 4, 1935, pages 793-794. $Mg_3Zn_3Al_2$ was prepared by melting the 3 metals together in the theoretical proportion and a homogeneous melt was obtained. Mg_4CuAl_6 could not be made by melting. $CuAl_2$, Al and Mg in powder form were pressed under 20,000 atm. and heated 60 hours at 500° to alloy them. Twelve alloys of various compositions were made and examined microscopically and by X-rays. Only the alloy corresponding to the formula Mg_4CuAl_6 showed only lines corresponding to a cubic lattice. $Mg_3Zn_3Al_2$ is also cubic. Both compounds contain approximately the same atomic % of Mg, 37, and correspond to the formula $Mg_{37}X_{63}$, where X may be Cu, Zn or Al. The average radius of the X atom in both compounds is about the same, 1.39 A.U. and 1.41 A.U. The lattice constant, a, for $Mg_3Zn_3Al_2$ is 14.16 A.U. and for Mg_4CuAl_6 14.25 A.U. CEM (10)

Crystal Orientations in a Nickel Casting and Their Alteration by Rolling and Recrystallization (Über die kristallitenorientierung in einem Nickelgussstück und ihre Änderung beim Walzen und bei der Rekristallisation). G. Tammann & F. Laass. *Zeitschrift für Metallkunde,* Vol. 27, Apr. 1935, pages 86-88. A 4 cm. Ni cube was cut from a casting of the same cross section and orientations determined by observation of points of maximum light reflection; cubic, dodecahedral, and octahedral types were distinguished, the last being further divided into {111} and {211} groups. Orientation distributions are determined on the casting for faces parallel and perpendicular to the cooling surface, on cold rolled samples cut from the casting, and on these specimens when recrystallized, and correlated with similar information on Al and Cu. On the castings {111} surfaces predominate near the cooling face, {100} 12 mm. from the surface, similar to Al, and indicating most rapid grain growth in [111] direction when heat dissipation is fast, in [100] direction when slow. However, Cu showed {100} orientation. Changes in orientation during rolling are the same as for Al and Cu. With increasing reductions the fraction of octahedral types increases and alignment of these in [111] direction occurs. However, up to 20% reduction Ni showed an anomalous decrease of the octahedral type and increase of cubic orientations, which cannot be explained by slip on {111} planes in the [111] direction. Samples which had been reduced 33% recrystallized at 750°, while recrystallization occurred at 650° after 90% reduction. In both cases grains were too small to permit orientation determinations until after heating to 1300° when octahedral surfaces predominated, as in Al, whereas Cu showed mainly {100}. GD (10)

Grain Growth in Carbonyl Iron and Preparation of Single Crystals of Iron (Kornwachstum im Karbonyleisen und Herstellung von Eiseneinkristallen). W. Tangerding. *Archiv für das Eisenhüttenwesen,* Vol. 9, Aug. 1935, pages 113-114. Carbonyl iron annealed at 850° C. first in air for 10 hrs. then in H_2 for 75 hrs. became very coarse grained even unicrystalline. Apparently hindrance to grain growth is greatly diminished after the last traces of C, O_2, and other impurities are eliminated in this way. Veining in this carbonyl iron appeared after more rapid cooling. The presence of veining increased the coercive force, confirming the view that veining indicates a disturbance of the α-iron lattice, accompanied by the presence of very slight traces of impurities. A Study of Chemical Equilibria in Melts (matte and Slag). A. N. Volsky & P. A. Agracheva. *Tzvetnuie Metallui,* Apr. 1935, pages 92-114. In Russian. 1. *Dissociation Pressure of Sulphides in Molten Slags.* On the basis of theoretical analysis of equilibrium between matte and slag the authors show the importance for theoretical metallurgy of determinations of the relation between the dissociation pressure of sulphides and oxides and their concentrations in their melts. Experimental methods developed by the authors for determination of dissociation pressures of sulphides are described. The authors determined the relation between the dissociation pressures of Ag_2S and FeS and their concentration in their solution (molten) in Cu_2S. The dissociation pressures of sulphides are shown to be considerably lowered as their concentration in the melt decreases. The mass-action constant for the reaction of dissociation of sulphides in melts does not remain constant, but is a function of concentration of these sulphides in the melt, and is decreased as the concentration decreases. 2. *Dissociation Pressure of Oxides Dissolved in Molten Slags.* The relation of dissociation pressures of FeO and its concentration in molten slags was determined. With decreasing concentration of oxide of a given metal in molten slag the equilibrium concentration of CO_2 in the mixtures of CO and CO_2 decreases. When oxides of 2 metals of different affinities for O_2 are present in slags, different concentrations of these oxides are required to produce equal dissociation pressures. The concentration is greater for the metal of greater affinity for oxygen. When this condition of equal dissociation pressures is realized both metals will be reduced simultaneously. This explains e.g., the reduction of Fe in the smelting of Cu, Pb, Ni and Sn ores in spite of the fact that certain amounts of Cu, Pb, Ni, Sn remain unreduced, although these metals possess lower affinity for oxygen than the Fe. In the oxidizing refining of metals the concentration of oxides of given metals dissolved in slag in contact with metal bath is reflected in the oxidizing action of slag on the metal bath through the decreasing dissociation pressure of oxides as their concentration in the slag decreases. A Refinement of the Heisenberg Theory of Ferro-Magnetism Applicable to Simple Cubic Crystals. Charles H. Fay. *Proceedings, National Academy of Sciences,* Vol. 21, Sept. 1935, pages 537-542. Results agreeing closely with those of the simple Heisenberg theory, but differing widely from the results of the use of the Gaussian distribution, seem to indicate that the simple approximation is better than the Gaussian. The order of validity of the simple approximation is perhaps as good as that of the other assumptions of the Heisenberg theory except at low temperatures. EF (10)

Crystals and the Polarising Microscope. N. H. Hartshorne & A. Stuart. Longmans, Green & Company, New York, 1934. Cloth, 5½ x 8¾ inches, 272 pages. Price $6.00.

The authors of this book are convinced that the polarising (or "petrographic") microscope should be widely used by chemists as a rapid means for diagnosing known compounds and for satisfactorily describing new ones, and they succeed in convincing the reader to this effect. One is inclined to believe, after reading this book, that the neglect of this tool by the average chemist is because the books that have been available up to the present on the polarising microscope have been written for the mineralogist and geologist, or, if directed at the chemist, have bristled with a multitude of details and complexities quite unnecessary for his purpose. The authors indicate that the apparatus is not elaborate and that the operations by which the optical properties of crystals are determined may be done quickly and simply. To clinch their argument for the general adoption of the method they give a summary of some fifty recent chemical researches in which the polarising microscope has been of considerable value, including, for example, the studies at the Geophysical Laboratory and the Bureau of Standards on equilibria in numerous systems of refractory oxides. As nearly all crystalline materials except metals are sufficiently transparent to be studied by transmitted light, the technique is widely applicable. The book, however, makes the field look rather too easy; a chemist cannot read the book one day and expect to go into the laboratory with it the next. If this were true, there would be little excuse for the college courses (usually graduate ones) that are customarily taken before entering the field!

The book is a manual on the symmetry and optical properties of crystals, the construction and care of polarising microscopes, and the procedure in the microscopic examination of crystals. It also includes 14 simple laboratory experiments. It is written for chemists and others who know something of the fundamentals of lenses and the phenomenon of interference, but who do not wish to consider any details of the method that are unnecessary in making chemical applications. There is no mathematics in the book; there are no tabulations of optical data of different compounds, but references are given to the best sources of this information; while no photographs of the interference figures are given, they are amply described with the aid of drawings. The book does not cover the recent metallographic studies by the reflection of polarised light from polished surfaces.

The book is to be highly recommended to those working with slags, refractories, ceramics, and various impurities in industrial materials. It will definitely help to increase the number of chemists who publish definite quantitative optical data and to decrease the number who describe the results of a crystallization in a casual way, such as "pale pink nodules" or "tufts of white flattened needles," which is of no value to subsequent observers who crystallize under somewhat different conditions. C. S. Barrett (10) -B-

Magnetism and the Electronic State of Metallic Solid Solutions and Elements (Magnetismus und Elektronenzustand Metallischer Mischkristalle und Elemente). U. Dehlinger. *Zeitschrift für Elektrochemie,* Vol. 41, Sept. 1935, pages 657-659. It is found that the theoretical magneton-composition curves for Ni-Co, Ni-Fe and Co-Fe solid solutions fall above the experimental curves. The theoretical curve is based on the assumption that each atom has given one *s* electron to the electron gas. This does not change the magnetic moment of the resulting atomic shell. The magnetic moments of Ni, Co and Fe then will be respectively 1, 2 and 3 Bohr magnetons. The difference between the curves for Fe, Ni and Co is independent of the nature of the atomic shells and must therefore be dependent upon the electron gas. It may be concluded that in ferromagnetic and temperature-dependent paramagnetic metals and alloys the *s* electron gas is not magnetically completely saturated but is partially counteracted by the spin of the atomic shells. The explanation of the magnetic behavior of metals is based on the interaction of three extinction integrals, that pertaining to the interaction of the (1) atomic shells with each other, (2) *s* electrons with each other, and (3) atomic shells with the electron gas. Fe, Ni, Co, Cu and Mn and their alloys are discussed in this connection. HAS (10)

Phase Changes During Aging of Zinc-alloy Die Castings. I—Eutectoidal Decomposition of Beta Aluminum-zinc Phase and Its Relation to Dimensional Changes in Die Castings. M. L. Fuller & R. L. Wilcox. *Transactions American Institute of Mining & Metallurgical Engineers,* Vol. 117, 1935, pages 338-356. See *Metals & Alloys,* Vol. 5, Dec. 1934, page MA 580. (10)

Determination of Orientations of Metallic Crystals by Means of Back-reflection Laue Photographs. Alden B. Crystallographic Uniformity of Lineage Structure in Copper Single Crystals. Alden B. Greninger. *Transactions American Institute of Mining & Metallurgical Engineers,* Vol. 117, 1935, pages 75-88. Includes discussion. See *Metals & Alloys,* Vol. 6, July 1935, page MA 296L/6. (10)

Examination of Electrodeposited Nickel Coatings by X-ray Diffraction. W. A. Wood. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Vol. 20, Nov. 1935, supplement, pages 964-971. An X-ray diffraction examination has been made of specimens of electrodeposited Ni differing in hardness and initial brightness. The brightness was found to be associated with the degree of selective orientation of the metal grains, and the hardness with the degree of diffusion of the X-ray diffraction spectra. The diffusion of the lines is expressed in terms of fine-grain and lattice distortion, and the grain size was estimated from the broadening of the spectral lines for a series of deposits of known hardness. 6 references. Transformation Points in Nickel Steels (Sur les Points de Transformation des Aciers au Nickel). Marins Sauvageot & Edmond Rousseau. *Comptes Rendus,* Vol. 201, Oct. 7, 1935, pages 611-613. Curves show transformation points obtained by the Chevenard dilatometer for a steel (C 0.62%, Ni 6%, Cr 0.5% and Mo 0.42%) heated to the Ac_3 point and cooled slowly. FHC (10)

New Laue Camera and Reflection Image Obtained Therewith (Beschreibung einer neuen Lauekamera und des dazugehöriga Reflexnetzes). Erich Schmid. *Zeitschrift für Kristallographie,* Vol. 91, July 1935, pages 95-96. The new camera is said to overcome certain shortcomings of back-reflection and rotating crystal methods. The film is placed parallel to the incident X-ray beam, which strikes the sample at an angle. An X-ray picture of Sn and its evaluation are given as an example. EF (10)

Transformation of Magnetite at Low Temperatures. Hikorok̆u Shoji. *Bulletin Institute of Physical & Chemical Research, Tokyo,* Vol. 14, Aug. 1935, pages 679-680. In Japanese. *Scientific Papers & Abstracts Bulletin Institute of Physical & Chemical Research, Tokyo,* Vol. 27, Aug. 1935, page 45. In English. Laue photographs of magnetite at room and liquid N temperature showed no evidence of transformation. WH (10)

Heats of Transformation in Iron (Untersuchungen über die Wärmetönung bei den Umwandlungen des Eisens). H. v. Steinwehr & A. Schulze. *Zeitschrift für Metallkunde,* Vol. 27, June 1935, pages 129-132. The heats of transformation at the A_2 and A_3 points of vacuum melted electrolytic iron, containing 0.03% Mn and a trace of Si, were determined by a calorimetric procedure already described. (*Zeitschrift für Metallkunde,* Vol. 26, 1934, page 130). In a series of 5 experiments the magnetic transformation was found to begin near 790° and end at 710° giving an average heat of transformation of 4.8 ± 0.02 cal./g. The change from γ to α Fe began at 894° and ended at 870°. For 6 runs the average value for the heat evolved was 6.2 ± 0.08 cal./g. GD (10)

Tetragonal Martensite in Carbon Steels. Zenji Nishiyama. *Science Reports Tohoku Imperial University,* Vol. 24, Nov. 1935, pages 517-522. To confirm the view that tetragonal or α martensite is an interstitial solid solution of C in Fe, the lattice constants were calculated from the radii of the sphere of action of Fe and C atoms. Results agreed fairly well with observed values on the change of lattice constant with C content, thus adding confirmation to the solid solution theory. BWG (10)

A Back-reflection Laue Method for Determining Crystal Orientation. Alden B. Greninger. *Zeitschrift für Kristallographie,* Vol. 91, Oct. 1935, pages 424-453. In English. See *Metals & Alloys,* Vol. 6, May 1935, page Ma 205R/3. EF (10)

Constitution and Properties of Cadmium-tin Alloys (Konstitution und Eigenschaften von Kadmium-Zinn-Legierungen). *Die Metallbörse,* Vol. 16, 1935, pages 754-755. See *Metals & Alloys,* Vol. 6, May 1935, page MA 203L/6. EF (10)

On the Theory of Superlattice Structures in Alloys. William Hume-Rothery & Herbert M. Powell. *Zeitschrift für Kristallographie,* Vol. 91, July 1935, pages 23-47. In English. After summing up the outstanding examples of observed superlattices, the Fe_3Al, FeAl, and the Cu_3Au superlattices are discussed at length and a theory of superlattice structures is set forth. Effect of grain Size on the Beginning of Supraconductivity (Der Einfluss der Kristallitgrösse auf den Eintritt der Supraleitung) K. Steiner & P. Grassmann. *Physikalische Zeitschrift,* Vol. 35, Aug. 1, 1935, pages 516-519. Experiments on annealed, worked, and recrystallized Sn wires showed that the transitional curve to supraconductivity is affected by grain size. **Effect of Bends on Wires on the Beginning of Supraconductivity (Über den Einfluss von Knickungen an Drähten auf den Eintritt der Supraleitung)** W. Meissner, K. Steiner & P. Grassmann. *Physikalische Zeitschrift,* Vol. 36, Aug. 1, 1935, pages 519-520. The initial part of the supraconductivity curve is shifted to lower temperatures by bends in In and Ta wires. EF (10)

The Crystal Structure of Gallium. A. J. Bradley. *Zeitschrift für Kristallographie,* Vol. 91, Sept. 1935, pages 302-316. In English. A redetermination of the structure of metallic Ga by the X-ray powder method confirmed Laue's orthorhombic structure (*Zeitschrift für Kristallographie,* Sect. A, Vol. 84, 1933, page 256) but photographs with Ni-K α radiation showed that all 3 axes were different in length: a = 4.5167 A.U.; b = 4.5107 A.U. and c = 7.6448 A.U. The axial ratios are a : b : c = 1 : 0.99868 : 1.69257. The space group is Va^{18}. EF (10)

Etching for Metallographic Investigations (Herstellung metallographischer Aetzungen für die metallographische Untersuchung) *Die Metallbörse,* Vol. 25, Aug. 14, 1935, pages 1026-1027; Aug. 17, 1935, page 1042. A useful chart gives 15 etching reagents, the composition, application, and etching effect of which are considered. Proper grinding and polishing of specimens for metallographic work are also taken up. EF (10)

X-ray Study of Aluminum Barium Alloys (Röntgenographische Untersuchung der Legierungsreihe Aluminium-Barium). K. R. Andress & E. Alberti. *Zeitschrift für Metallkunde,* Vol. 27, June 1935, pages 126-128. Alloys containing 0.5% increments of Ba from 0 to the eutectic at 2%, and 5% increments from this point to 56% Ba were studied by back-reflection powder photograms. A constant a_0 value for Al was found throughout this range, indicating no solid solution field. Only one intermetallic phase, corresponding to Al_4Ba at 56% Ba, was observed. Photograms of cleavage sections of Al_4Ba showed that it may be considered a body-centered-tetragonal lattice of Ba atoms (a = b = 4.53 A.U., c = 11.1 A.U.) whose interstices are filled with Al atoms in the positions of the two types (00u) and (0 ½ ¼), where u is 0.38. GD (10)

Structural Changes in Gray Iron Subsequent to Annealing (Variazioni strutturali nella Ghisa grigia consequenti a Ricottura). V. S. Prever. *Industria Meccanica,* Vol. 17, Nov. 1935, pages 978-982. An ordinary gray Fe was heated to different temperatures and for different lengths of time and the structural changes were observed. No typical changes can, however, he stated; the complexity of the phenomena does not permit a uniform explanation. Individual micrographic examinations are required in most casts of metallographic determination. Ha (10)

Copper-Nickel-Zinc Alloys (Kupfer-Nickel-Zink-Legierungen). J. Schramm. K. Triltsch, Würzburg, 1935. Boards, 6 x 8 inches, 129 pages. Price 4 RM. Extensive phase rule study of the Cu-Ni-Zn system with many sections of the solid diagram. H. W. Gillett (10) -B-

Influence of Structural Characteristics on the Properties of Metals. N. A. Ziegler. *Industrial Heating,* Vol. 2, Oct. 1935, pages 575-579. The physical properties of steels, in particular the structural characteristics, are determined by (1) condition of metallic grains before the heat treatment, (2) condition of metallic grains (usually austenitic) at the heat treating temperature, (3) final or ultimate grain condition. Improve
High Speed Production
with Welding Electrodes and Dies
of MALLORY
ELKALOY

Mallory welding electrodes and dies of Elkaloy and Mallory water cooled holders are playing an increasingly important part throughout industrial America. When properly water cooled Mallory Elkaloy lasts 3 to 8 times longer than copper assuring greater welding uniformity and eliminating frequent annoyance and expense of "mushrooming" and redressing.

Submit your welding problems to Mallory engineers. Advise them of the kind and thickness of the two metals you wish to join. Their recommendations will meet your requirements effectively and economically.

Mallory also makes welding electrodes and dies to your specifications.

11. PROPERTIES OF METALS AND ALLOYS

Recent Developments in Metals Sealing into Glass. HOWARD SCOTT. *Journal of the Franklin Institute*, Vol. 220, Dec. 1935, pages 733-753. Co added to low expansivity Ni steels increases the temperature to which the steel can be heated and still retain the property of low expansivity. As a result, Fe-base alloys may now be sealed in hard glass. FHC (11)

Calculation of Energy Values of Metals from Recrystallization Data (Die Berechnung der Auflockerungswärme der Metalle aus Rekristallisationsdaten). J. A. M. VAN LIEMPT. *Zeitschrift für Physik*, Vol. 96, Sept. 7, 1934, pages 534-541. From recrystallization data, the following equation is derived to explain the heat energy governing the mobility of atoms grouped in a space lattice.

$$E = 4.6\ C + 1200\ \beta$$

Where E = heat governing the loosening of atoms from their space group limitations,
C = recrystallization constant, and
β = deformation gradient.

Energy relations of the loosening of atoms can also be explained on the basis of diffusion phenomena and on the elastic recovery of metallic atoms. FHC (11)

Metals—Their Structure, Characteristics and Idiosyncrasies. V. N. KRIVOBOK. *Canadian Chemistry & Metallurgy*, Vol. 20, Feb. 1936, pages 48, 50. The general application of studies of atomic arrangement is most apparent in the alloys. Alloys possess the same general atomic arrangement as the pure metals. The characteristics of alloys of Fe and C; Fe and Si; Fe, Ni and Cr, etc., are outlined. From the periodic table of elements it is possible to decide what type of diagram will be obtained with a certain alloy and thus roughly determine its utility even before manufacture. Mechanical testing methods indicate in a crude way only changes in metals, and to understand what takes place when the properties of a metal suddenly change we must resort to studies of the atomic arrangement and other exact methods of determining what is taking place. The changes in properties of metals may also be explained, on the basis of a change in the number of slip planes, with a consequent change in the ductility of the metal. WHB (11)

A. J. PHILLIPS, SECTION EDITOR

Crystallization in Binary Systems with Eutectics (Ein Beitrag zur Kristallisation binärer Systeme mit Eutektikum). E. RAUB. *Zeitschrift für Metallkunde*, Vol. 27, Apr. 1935, pages 77-83. The grain size and structure in binary systems were observed by metallographic methods. It was found that these are both determined by the characteristics of the primary constituent, but are also influenced by other factors which affect pure metals, such as, size and shape of the casting, pouring temperature, and rate of cooling. Experiments have shown that the structure has little effect on the mechanical properties when the constituents have widely varying properties, but the structure is determinative when the components have similar properties. Using 83% Ag-Cu alloy as an example of the latter type it is shown that recrystallization and deformation processes are similar to those in pure metals and solid solutions, the distribution of phases having little importance. For this alloy he shows that cold rolling leads to anisotropy, as in pure metals, as does subsequent recrystallization, both effects being strongest at high reduction and high annealing temperature. Demonstrated by data on extension and tensile strength, the first shows a maximum, the latter a minimum in test foils cut 45° to rolling direction. GD (11a)

The Ductile Alloys of Copper and Silicon. H. H. PARRETT. *Metal Industry*, London, Vol. 46, Mar. 29, 1935, pages 349-350. The author describes a series of Cu-Si alloys containing 3-5% Si investigated to determine the composition giving the highest strength and ductility and the amenity of the alloys to such heavy working as the production of fine wire. His conclusions show that the alloys having 4.00-4.70% Si are ductile and have a tensile strength superior to phosphor bronze. If the Si content is above 4.70% the alloys become brittle. The Cu-Si alloys are not as resistant to sea-water corrosion as phosphor bronze. Rapid continuous annealing at as low a temperature as possible is necessary for these alloys. HBG (11a)

Embrittlement of Uranium by Small Amounts of Aluminum and Iron. H. W. HIGHRITER & W. C. LILLIENDAHL. *Transactions American Institute of Mining & Metallurgical Engineers*, Vol. 117, 1935, pages 381-386. Includes discussion. See *Metals & Alloys*, Vol. 6, Oct. 1935, page MA 411L/10. (11a)

Aluminum Alloys—Patent List (Aluminium-Legierungen, Patentsammlung) A. GRÜTZNER & G. APEL. Supplement to section on aluminum in Gmelins Handbuch der anorganischen Chemie. Verlag Chemie, Berlin, 1936. Paper, 7 x 10 inches, 342 pages. Price 35 RM.

Index, by alloy composition, of patents on Al alloys. Patents of Germany, England, France, Austria, Switzerland and the U. S. from 1887 to May 1935 are listed. The Al alloys containing Si cover 113 pages, ranging from the binary group up to Al-Si-Co-Cr-Cu-Mg-Mn-Mo-Ni-Sb. If an element is mentioned in the patent specification as being a possible addition or substitute, that element is indexed. It must have been a huge task to prepare the index, which would be a great aid in patent searches. H. W. Gillett (11a) -B-

Modulus of Elasticity for Cu-Be Alloys (Sur le Module d'Élasticité des Alliages Cuivre-Beryllium). LÉON GUILLET. *Comptes Rendus*, Vol. 201, Nov. 18, 1935, pages 960-962. Author demonstrates with graphs the increase in hardness and in the modulus of elasticity for Cu alloys with a Be content varying from 2 to 18.5% by weight. With 15% Be the alloy has a modulus equal to that of steel. FHC (11a)

Compression Requirements for Avional Samples (Knickbeanspruchung an Avional-Stäben). K. Guler. *Zeitschrift für Metallkunde,* Vol. 27, June 1935, pages 137-138. Stress-strain curves were obtained for a high quality Avional containing 0.7% Si, 0.7% Mn, 0.7% Mg, and 4% Cu. The compression elastic modulus was calculated from these and related to the shape of the specimen. The compression experiments were made on an apparatus designed to insure uniform aplication of load. GD (11a)

Experiments on the Electrical Resistance of Copper and Some Copper Alloy Wires. Clement Blazey. *Journal Institute of Metals,* Vol. 58, Nov. 1935, pages 503-522 (*Advance Copy* No. 719). Electrical resistances of 7 samples of high-conductivity Cu, a furnace-refined Cu, 2 Cu-Cd alloys, and some specially prepared samples were measured after annealing in CO_2 at temperatures over the range 300-950°C. One series of samples was quenched from the annealing temperature and another was slowly cooled. In general, a minimum resistance resulted from annealing at 500°C. and the resistance gradually increased as the annealing temperature was increased above this temperature. The increase, however, tended to disappear when the wires were slowly cooled from the annealing temperature or when the wires were reheated to 500°C. In wire-bar Cu the increase in resistance on quenching from 950°C. varied from 0.5 to 1%. Additions of S and Se to Cu increased resistance increase brought about by quenching from a high temperature. Causes for increase in resistance are discussed. The most probable cause is the increased solubility of some element present in all the Cu examined—possibly O. JLG (11a)

The Bronzes as Engineering Materials. F. Johnstone Taylor. *Metal Industry,* London, Vol. 46, Apr. 26, 1935, pages 453-456. The multiplicity of alloys now available has made necessary closer coöperation between metallurgist and brass-foundrymen. The variety of alloys available for various forms of fabrication are indicated. While the major purpose of casting in bronze is to resist corrosion, high strength—particularly at high temperatures—is frequently a requisite. The author discusses an 85:5 Cu-Sn (Editor's note: Probably an error) corrosion resistance bronze that is superior in many ways to gun-metal and Mn-bronze. The following data on this material are reported:

Type of Material	Ultimate Strength Tons.	Reduc. in Area, %	Elong. in 2", %	Brinell	Density
Cast	21	34	39	72	8.62
Drawn Rod	44	60	30	130-171	
Cast Material (at 1000° F.)	20				

This material is suitable for high temperature work such as pressure valves for superheated steam-lines, for use in oil lines, and for use in brewing, distilling and paper-making trades where corrosive liquids must be withstood. The variety of proprietary metals developed for certain superior physical properties are considered and the effect of variation of the major constituents and the influence of metallic additions are indicated. The advantages of certain alloys of the solid solution type, such as Everdur, their physical properties and certain commercial applications are noted. Foundry practice with emphasis on pyrometric temperature control is recommended. The author describes a method for ensuring a pressure-tight casting. Methods of casting Ni-bronze and Si-Cu are given and the importance of gating is emphasized. HBG (11a)

Vapor Pressure Abnormalities of Amalgams (Dampfdruckabnormalitäten bei kapillaraktiven Amalgamen). Hans H. von Halbon. *Helvetia Physica Acta,* Vol. 8, Feb. 15, 1935, pages 65-81. The vapor pressures of K, Na and Zn amalgams were determined by the author's method which depends on the intensity of absorption of resonance radiation by the vapor. Even when the concentration of K, Na and Zn is very low, drastic decreases of the vapor pressure of Hg were noticed. This phenomenon is attributed to surface adsorption of the metals since stirring restored almost completely the vapor pressure of pure Hg. EF (11a)

Non-Ferrous Casting Alloys of High Strength. A. J. Murphy. *Metal Industry,* London, Vol. 47, Sept. 6, 1935, pages 229-232; Sept. 27, 1935, pages 319-321; Oct. 4, 1935, pages 346-349; *Foundry Trade Journal,* Vol. 53, Oct. 10, 1935, pages 271-274; Oct. 17, 1935, pages 291-294; *Canadian Chemistry & Metallurgy,* Vol. 19, Sept. 1935, pages 245-247, 250; Oct. 1935, pages 274, 276-277. Exchange paper of the Inst. of British Foundrymen to the Annual Convention of the A.F.A. at Toronto, Can., Aug. 20-23, 1935. The author outlines a wide range of alloys which, in addition to high strength, have other desirable properties. The alloys considered include Mn-bronze, Al-bronze, Ni-alloys, Zn-alloys, Al-alloys, Ceralumin-alloys, and Mg-alloys. The physical properties of these alloys, necessary precautions to be taken, the effect of additions, applications and the relation of high strength to other properties are included in the discussion. Microstructures of some of the alloys discussed are included. WHB+AIK+HBG (11a)

Hardness of Heat-Treated Al Bronzes. I. Binary Bronzes of the Type 90- 10 (Ricerche sulla durezza di rinvenimento dei bronzi d'alluminio. I. I bronzi binari del tipo 90- 10). C. Panseri. *Alluminio,* Vol. 4, July-Aug. 1935, pages 213-217. The variation in hardness with the temperature of heat-treatment of 2 types of Al bronzes has been determined. The bronzes contained 10.85 and 10.68% Al, respectively, but type "O" had 0.26% Fe and 0.07% Si, while type "OO" had only 0.02% Fe and 0.04% Si. Samples were hardened at 900°C., and then tempered at increasing temperatures. Type "O" increases in hardness as the temperature of heat-treatment increases, up to a maximum of 400°C.; then there is a sudden drop in hardness as the temperature of heat-treatment is increased to 650°C. where it reaches a minimum, which is retained with heat-treatment, up to 900°C. Type "OO" bronze behaves similarly. The maximum hardness (Brinell, 250 kg. load, 5 mm. ball, 30 seconds time) varies from 221, when heat-treatment is carried out at 250°C., up to a maximum of 235, and then down to 164 for temperatures of 650°C. and above. For type "OO" the hardness varies from 218 to a maximum of 255 at 350°C., and down to 118 when the heat-treatment is carried out at 750°C. and above. AWC (11a)

Note on the Effect of Interrupted Straining on the Elongation of Lead. J. C. Chaston. *Engineering,* Vol. 140, Oct. 11, 1935, pages 397-398; Vol. 160, Oct. 4, 1935, page 342. See *Metals & Alloys,* Vol. 6, Sept. 1935, page MA 372L/9. LFM (11a)

OFHC
REG. U.S. PAT. OFF.

OXYGEN-FREE HIGH CONDUCTIVITY

A Superior Copper for All Purposes

OFHC Copper conforms to the A.S.T.M. Specification for electrolytic copper wirebars, cakes, etc., B5-27 with regard to metal content and resistivity, and is free from cuprous oxide.

OFHC Copper is characterized by its freedom from casting defects and its bar-for-bar uniformity. Its freedom from oxygen results in great ductility and toughness as evidenced by its high reduction of area and resistance to impact.

OFHC Copper withstands more working in hard condition when tensile strength is greatest, making it especially suited for products subjected to severe fabricating or service conditions.

Copies of a schedule of weights and dimensions of **OFHC** wirebars, cakes and billets, and a booklet containing technical information will be gladly furnished upon request.

Effect of Small Quantities of Bismuth and Manganese on Tin (Ueber den Einfluss kleiner Mengen von Wismut und Mangan auf Zinn). *Die Metallbörse,* Vol. 35, May 18, 1935, pages 625-626. Literature survey emphasizing recent investigations of Hanson & Sandford. See *Metals & Alloys,* Vol. 6, Aug. 1935, page MA 334R/3. EF (11a)

Determination of the Melting Points of Calcium, Strontium, and Barium (Bestimmung der Schmelzpunkte von Kalzium, Strontium, und Barium). F. Hoffmann & A. Schulze. *Zeitschrift für Metallkunde,* Vol. 27, July 1935, pages 155-158; *Physikalische Zeitschrift,* Vol. 36, July 1, 1935, pages 453-458. Samples weighing about 20 g. were melted in pure Fe crucibles in oxygen-free argon within a vacuum oven. Heating and cooling curves were taken with a precious metal thermocouple and the accuracy of determination of the melting point estimated as ±1°. Three samples of technical Ca of about 95% purity gave melting points of 810°, 813°, 819° while resublimed material of 99.9% purity melted at 849°. A 99.9% commercial Sr sample melted at 756° but resublimed Sr melted at 771°. Technical Ba samples of 99.9% and 97% purity melted at 670° and 669° respectively, while 99.8% resublimed Ba melted at 704°. In all cases the differences found between technical and resublimed material are attributed to the presence of nitrides in the former. EF+GD (11a)

The Most Important Properties of Fabricated Light Metals from the Production Viewpoint (Die wichtigsten Eigenschaften der mechanisch verarbeiteten Leichtmetalle für die Betriebspraxis). H. Jensch. *Metallwaren Industrie & Galvano Technik, Sect. Werkstoffkunde & Verarbeitungstechnik,* Vol. 33, Apr. 1, 1935, pages 150-156. Tabulates and discusses physical properties of 13 important light alloys. Their behavior under corrosive conditions is briefly dealt with. EF (11a)

Dental Alloy Containing Silver as Base. Senji Hatada. *Bulletin Institute of Physical & Chemical Research, Tokyo,* Vol. 14, Sept. 1935, pages 885-890. In Japanese. *Scientific Papers & Abstracts Institute of Physical & Chemical Research, Tokyo,* Vol. 27/28, Sept. 1935, pages 57-58. In English. Substitutes for Au, Pt and their alloys were studied chemically. The favorable physical properties of Ag are pointed out and attempts were made to overcome its main drawback, the tendency towards discoloration. A great number of binary Ag alloys were submitted to corrosion tests and an alloy containing 70% Ag and 30% Pd was found to be highly corrosion resistant and to possess excellent physical properties with respect to its use as a dental alloy. WH (11a)

A New Bearing Metal—A Lead Base Alloy. C. H. Hack. *Metal Progress,* Vol. 28, Nov. 1935, pages 61-64, 72. Describes a lead base bearing alloy hardened by Ca and other alloying elements. It has in addition to excellent bearing properties a resistance to damage by temperatures up to 560° F. WLC (11a)

Temper Hardening of Commercial Nickel-Coppers Containing Phosphorus. E. C. Rollason & T. G. Bamford. *Metals & Alloys,* Vol. 6, Dec. 1935, pages 345-346, 349. Age hardening characteristics of 3 Cu alloys of 1.72%, 1.73% and 2.33% Ni and 0.03%, 0.11% and 0.03% P respectively are reported. WLC (11a)

Non-Ferrous Metals and Alloys. Report of Committee B-2. R. F. MEHL, Chairman. *Proceedings American Society for Testing Materials,* Vol. 35, Part I, 1935, pages 136-140. Progress report primarily on specifications. VVK (11a)

A Discussion of the Transition Metals on the Basis of Quantum Mechanics. N. F. MOTT. *Proceedings Physical Society,* Vol. 47, July 1935, pages 571-588. Magnetic and electrical properties of Co, Ni, Pd, and their alloys with Cu, Ag, Au are discussed on the basis of quantum mechanics. The relative high resistance of the transition metals can be explained. The number of electrons in the outermost state must be 0.6 per atom in transition metals and 1 in noble metals. 32 references. JCC (11a)

Standardization of Aluminum Alloys. (Die Normung der Aluminiumlegierungen). W. KOOPMAN. *Zeitschrift Verein deutscher Ingenieure,* Vol. 79, Nov. 30, 1935, pages 1445-1446. The basic considerations for a standardization of Al alloys are explained as they are applied in the German standard DIN 1713. Conditions of the metal as delivered, hardened or cold deformed, possibilities and manners of welding, corrosion resistance and purpose of application have been taken into account. Ha (11a)

Zinc (Zink) German Committee on Standards for Non-Ferrous Metals. *Zeitschrift für Metallkunde,* Vol. 27, Aug. 1935, page 191. Analytical requirements are set down for different classes of commercial Zn. GD (11a)

The Physical Properties and Annealing Characteristics of Standard Nickel Silver Alloys. MAURICE COOK. *Journal Institute of Metals,* Vol. 58, Dec. 1935, pages 551-565 (Advance Copy No. 721). A series of alloys containing approximately 63% Cu, from 10 to 30% Ni, and the balance Zn were melted and cast into ingots 1⅝″ thick. Ingots were rolled to 0.30″ by a sequence of rolling and annealing. These strips were then rolled to 0.031″, samples being taken at stages of 10% reduction in thickness. Mechanical properties and change in properties on annealing were then determined for the material given different reductions. The modulus of elasticity increased progressively with Ni content, and in annealed condition hardness also increased with Ni content. The difference in hardness was not maintained when the materials were cold rolled, the hardness increase decreasing as the Ni content increased. The temperature at which softening begins on annealing increases with Ni content. Density, electric conductivity, thermal conductivity, and thermal expansion of the alloys were also determined. 29 references. JLG (11a)

Softening and Recrystallization of Pure Aluminum. (Ueber die Erweichung und Rekristallisation von reinem Aluminium). *Aluminium,* Vol. 17, Nov. 1935, pages 575-576. The experiments of Calvet to determine the effect of impurities on the velocity of softening are discussed. The velocity depends to a large degree on the purity of Al. The recrystallization velocity is very high for the very pure metal and increases rapidly with increasing temperature. Ha (11a)

Beryllium. *Metallurgist,* Dec. 1935, pages 91-93. A review of the production, properties and applications of Be and Be alloys. VVK (11a)

A New Low-Melting Alloy. SIDNEY J. FRENCH. *Industrial & Engineering Chemistry,* Vol. 27, Dec. 1935, pages 1464-1465. The new alloy consists of "Lipowitz eutectic alloy" plus indium, and has a m. p. of 46.5° C. Some possible applications of the alloy are suggested, and cooling curves are shown. MEH (11a)

Melting Points of Eutectics. Lipowitz Alloy and Wood's Metal. SIDNEY J. FRENCH. *Industrial & Engineering Chemistry,* Vol. 28, Jan. 1936, pages 111-113. The author gives the compositions of the 2 alloys, and the melting range is given as 69.7°-71.7° C. for both. It is thought that the abnormally low m.p.'s reported in the literature may be those of undercooled alloys or amalgams, and the author suggests the name "quaternary eutectic" with a designation of its composition and melting range, in place of the older, confusing names. Copper Wire, Report of Committee B-1. J. A. CAPP, Chairman. *Proceedings American Society for Testing Materials,* Vol. 35, Part I, 1935, pages 133-135. Progress report on specifications. VVK (11a)

Properties of Silumin Containing Magnesium (Die Eigenschaften von magnesiumhaltigem Silumin (Silumin Gamma)) G. SACHS & E. SCHEUER. *Metallwirtschaft,* Vol. 14, Nov. 22, 1935, pages 937-941; Nov. 29, 1935, pages 972-975. This alloy, containing 12% Si, .4% Mg, .5% Mn, balance Al, is especially suitable for large and complicated castings which require high strength. Large castings can be quenched in water during heat treating without danger of cracking. Slight warping can be overcome by straighening after quenching, but after aging this alloy is too stiff to straighten. It was found that in castings quenched under ordinary conditions the hardness of thin sections was less than that of heavy sections. This was due to cooling of the thin sections during the transfer from furnace to quench. Uniform results were obtained when this interval was reduced to 10 seconds by improved equipment. It is essential to use cold water for quenching and the highest possible temperature, usually 525° C. after 3 hours heating. At about 550° the Al-Si-Mg_2Si eutectic melts and leaves voids at the grain boundaries. Very large castings are apt to be too soft due to the relatively large interval between Mg_2Si dendrites and resulting slow diffusion. This is overcome by increasing the heating time and by the use of chills. The use of salt as a flux should be avoided as it lowers the Mg content and results in low physical properties. The aging treatment is not critical, 20 hours are required at 150° and 4 hours at 180°. The endurance limit is quite high in the quenched state, but is not increased by aging. It is not lowered by running water over the test piece. Test bars cut from 14 production castings averaged 31.3 kg./mm.^{2} tensile strength, 2% elongation, 109 Brinell hardness, and 7 kg./mm.^{2} endurance limit. Still better properties are obtained in permanent mold castings. Silumin gamma is not recommended for castings which are subjected continuously to temperatures higher than 150° to 170°. 12 references. CEM (11a)

Electrical Resistance Alloys. F. P. PETERS. *Paper, Electrochemical Society,* Oct. 1935, pages 351-362. A resistance alloy should have the following properties: (1) High resistance, (2) low temperature coefficient of resistivity, (3) resistance to oxidation, (4) high melting point, (5) strength at high temperatures, (6) reasonable cost. The 80-20 Ni-Cr alloys fill these requirements. Some other alloys containing Fe-Cr-Al and Fe-Cr-Al-Co exceed 80-20 Ni-Cr have higher resistivity and better resistance to oxidation but they exhibit a permanent increase in length characteristic, lack of strength at high temperature and are difficult to fabricate. GBH (11a)

Magnesium Alloy Developed for Die-Cast Products. J. B. NEALEY. *Steel,* Vol. 98, Jan. 20, 1936, pages 29-30. Dowmetal can be produced in almost every known form. It can be die cast successfully by the press-cast process. Dies used are similar to those used in die casting Al. However, larger fillets and rounding of sharp corners are often advantageous. Most commonly used die-casting alloy is Dowmetal G, which contains 89.9% Mg, 10.0% Al, and 0.1% Mn. It combines good casting properties with good mechanical properties. Forgings are employed where higher strength and impact properties are required than can be obtained with die castings. Press forgings are recommended in preference to hammer forgings because of greater time available for metal flow. Existing dies and equipment can be easily adapted. Where maximum strength is desired and forged part is not too intricate, Dowmetal alloys F(95.7% Mg, 4.0% Al, 0.3% Mn), J, and A(91.8% Mg, 8.0% Al, 0.2% Mn) generally are used in the order named. For moderately stressed parts subject to salt H_2O conditions M(98.5% Mg, 1.5% Mn) is used. Extruded bars and rods are used for forging stock instead of cast billets as they permit wider forging temperature range and greater speed of forging. Forging temperature ranges from 600° to 825° F. and 1 hr. at heat for each in. thickness should be allowed. Heat treatment is unnecessary as forging develops maximum strength. Tabulates physical properties of the various alloys and mechanical properties of cast alloys. MS (11a)

Study of Iron-carbon-aluminum Alloys. B. E. Somin, N. N. Lipchin & Yu. M. Margolin. *Kachestvennaya Stal,* No. 9, 1935, pages 22-37. In Russian. Specimens were prepared in high frequency induction furnace and contained 0.05 to 1.2% C and 4 to 16% Al in steps of 2%. All could be forged between 1000° and 1200° C. All samples were quenched at 1050° C. in oil, drawn 40 hours at 450° C. and finally annealed at 1100° for one hour and furnace cooled. At each stage of treatment specimens were studied for their structure, hardness, electrical resistance and magnetic properties. On most of them Curie point was determined. 4 and 6% Al alloys showed decrease of pearlite in annealed, and of martensite in quenched steels having the same C content with the rise of Al. Al shifts the pearlitic point to the right at the rate of 0.087% C for each % of Al. At 8% Al pearlite does not form any more and C is precipitated as η phase of F. R. Morral, *Journal Iron & Steel Institute,* 1934, throughout the grains. With higher C contents it is present as massive inclusions, but when C is removed, as on the outside of specimens, their shape approaches needles, either separately located or crossing each other. This is explained on the basis of anisotropic speed of crystallization of this substance. η phase reduces grain size causing gradual refining of the fracture with increasing C. Data of Keil & Jungwirth, *Archiv fuer Eisenhuettenwesen,* Vol. 4, 1931, page 221, on the complete lack of graphitization between 10 and 18% Al are fully supported. C is tied here in η phase, which is quite stable. The amount of it with the same C passes through a maximum at 12% Al and a minimum at 14% Al. C concentration in η phase is lowest at 12% and greatest at 14% Al corresponding to Fe_3Al. Electrical resistance shows anomalies both for high and low C steels due to the formation of superlattice. Quenching speed for low C was not high enough because with about 14% Al crystals passed from random orientation, at least partially. With sufficiently long drawing at low temperature, arrangement of the crystallites begins with 4% Al and depends, apparently, on the closeness of the composition to the stoichiometrical ratio, to 14% Al in this case. Degree of freedom from random orientation is greater after drawing than after annealing. Increasing Al content lowers magnetic induction both in quenched and drawn alloys. Higher C samples show a break at 8% Al after which induction increases to 12% Al and then continues to decrease. It is connected with η phase presence which concentrates in itself Al and C impoverishing the matrix in their respect when Al is below 14% and enriching it as soon as this figure is passed. This is supported by determination of Curie points. Up to 8% Al Curie points do not change remaining around 210° C. which indicates that one deals here with pure cementite. Between 6 and 8% Al a second point around 300° C. is observed. It corresponds to cementite containing some Al. At 10% Al the magnetic transformation point of η phase is observed, which changes with Al content. Magnetic induction of η phase in 12% Al, 1.0 C alloy is calculated. Coercive force is greatly lowered by Al, so that in annealed 12% Al, 1.0% C steel it is the same as in 0.05% C steel, less than 2 oersteds. Hardness passes through a maximum between 12 and 14% Al, both in quenched and annealed state. On drawing quenched alloys pronounced precipitation hardening takes place. Forging permits breaking η phase and cementite so that they become distributed within the grains which gives a material suitable for wire drawing. (11a)

The **Light Metals and Their Alloys (Les Métaux légers et leurs Alliages)** L. Guillet. Dunod, Paris, 1936. Paper, 6½ x 10 inches, 429 pages. Price 138 Fr.

This volume deals with the history, the ores, the production of the metals from the ores, the properties of the metals themselves and the economics involved, while the second, to be written in collaboration with J. Cournot, is to deal with the alloys, their mechanical and thermal treatment and their uses.

In the preface the author states that excellent treatises are available in English and German, but up-to-date ones in French are lacking. The Aluminum Industry, by Edwards, Frary and Jefferies, is so complete that, in this volume at least, relatively little of importance will be found not already adequately covered by those authors. Indeed the American reader will probably find more of interest in the illustrations, showing views of the interior of foreign plants, e.g. those of a 28,000-ampere cell, than in the text itself. The presentation is primarily that of an extensive "correlated abstract," chiefly citing published data, though often with illuminating remarks. However, it is often difficult to tell which of several processes described has the most commercial acceptance.

The sections on Mg, Be, Na, Ca, etc. are much less detailed than that on Al. The book will serve its purpose in France, since nothing so complete is available in French, but, since so much is available in English, the English-speaking metallurgist will be likely to use it but rarely, though its copious references and illustrations in particular make it worthy of a place on the shelves of those having to do with the light metals. H. W. Gillett (11a) -B-

Various Copper-Nickel Alloys (Les divers Alliages Cuivre-Nickel) Joseph Dhavernas. *Cuivre et Laiton,* Vol. 8, Dec. 30, 1935, pages 541-543. Alloys of Ni with Cu, Zn, bronzes and light metals are briefly reviewed. Cu-Ni alloys are now widely used as fire tubes and condenser tubes; the alloy with 20-30% Ni possesses a particularly high resistance to corrosion by seawater. The alloy with 45% Ni, "constantan," has a high thermo-electric force and a fairly constant electric resistance at varying temperatures. Alloys of Cu-Ni-Zn are the so-called "German Silvers" (Ni-silver) with 15 or less % Ni and 45-55% Cu. Ni added to Sn bronzes gives a much finer grain and improves the tensile strength. Al alloys with Ni additions up to 4% show increased hardness and strength. A heat-resistant alloy (Y) is composed of 92.5% Al, 4.0% Cu, 1.5% Mg, 2.0% Ni. Another light metal used for parts of combustion engines is a complex Al alloy containing Ni, Cu, Mg, Fe, Ti and Si. Ha (11a)

Longitudinal Thermoelectric Effect: (5) Silver. J. L. Ch'en & William Band. *Proceedings Physical Society,* Vol. 47, Sept. 1935, pages 904-909. The homogeneous thermoelectric constants for a Ag wire have been determined, and are shown to depend on the longitudinal tension. With zero tension, an abrupt change occurs near 200° C., and this is considered to be connected with the change of elastic limit. JCC (11a)

Plasticity of Bismuth. W. F. Berg & L. Sandler. *Nature,* Vol. 136, Dec. 7, 1935, page 915. Crystals of Bi were grown in vacuum and at atmospheric pressure in H_2, N_2 and CO_2. Under all conditions of growth some of the crystals obtained were soft, with slip occurring in tensile tests at room temperature. It is concluded that previous observations of lack of plasticity of Bi crystals are explained not by gas content but either by orientation unsuitable for slip or by strain hardening of crystals during freezing (especially with Bridgman's method). Hardening Characteristics of One Per Cent Carbon Tool Steels. T. G. Digges & Louis Jordan. *Transactions American Society for Metals,* Vol. 23, Dec. 1935, pages 839-860. 8 references. Discussion. 2 C steels were selected from 6 for their wide difference in grain size and hardenability. Prepared in 3 conditions, spheroidized, coarse pearlitic and sorbitic they were studied for grain size, grain growth and critical cooling rates. The composition of the deep hardening (uncontrolled grain size) and shallow hardening (controlled grain size) were respectively C-1.05% and 1.06%, Mn-0.28% and 0.26%, P-0.019% and 0.013%, S-0.013% and 0.011%, Si-0.22% and 0.19%, Cr-0.08% and 0.09%, Ni-0.13% and 0.10%, W not detected, Mo and V less than 0.01%, Al_2O_3-0.006% and 0.010%, acid soluble Al-0.001% and 0.008%, total Al-0.004% and 0.013%, H-0.0002% and 0.0003%, 0-0.007% and 0.009%, N-009% and 0.007%. Quenching temperatures employed were 1475°-1775° F. For temperatures below the solution point for all the C in austenite both grain size and cooling rate depend largely on initial structure. Above this point both steels approach a condition characteristic of the steel except that initial treatment exerts greater influence on the shallow hardening or controlled grain size steel above this point. Controlled steel shows marked change in cooling rate without change in grain size whereas the uncontrolled steel shows marked effect of grain size upon critical cooling rate. WLC (11b)

Heat Resisting High Alloy Chromium Tungsten Steel as a Material for Turbine Buckets. P. B. Mikhailov-Mikheiev. *Kachestvennaya Stal,* No. 8, 1935, pages 39-47. In Russian. For turbines operating at 550° C. and above bucket stock was previously developed which better withstood oxidation and was stronger than the usual low C 12-14% Cr alloy. Its composition was 0.5-0.7% C, 14-18% Cr and 1.5-2.0% Mo. In the present work a steel containing 0.6-0.7% C, 0.4% Si, 0.4% Mn, 17.5% Cr and 2.0-2.1% W was compared with it. The steel is composed in annealed state of ferrite and carbides which fully pass in solid solution only on heating to 1250° C., forming austenite. Its hardness after quenching does not decrease after heating to 1150° C. which was selected as maximum quenching temperature to produce 250 Brinell hardness. Quenching in oil at 1100°-1150° C. and drawing at 820° C. produces optimum properties, yield point 46-53 kg./mm.², tensile strength 73-76 kg./mm.², elongation 21-24%, Charpy impact 2.4-3 kg./cm.² and permits flat bending in cold. Its fatigue limit is 42-44 kg./mm.² as compared with 46-48 for Cr-Mo and 38-40 for 13% Cr steels. Short time tensile tests at high temperatures showed that Cr-W steel is weaker than Cr-Mo though only slightly. Yield point of Cr-W steel remains, however, practically the same, 35 kg./mm.², up to 500° C. while yield point of Cr-Mo steel drops continuously. Scaling resistance of both steels is practically the same up to 900° C. The steel can be used for the purpose intended. (11b)

Tool Steels (Les Aciers à outils) II. André Michel. *Métaux,* Vol. 10, Aug. 1935, pages 180-187. General remarks on alloy tool steels. GTM (11b)

Heat Resistance, High Temperature Strength and Intercrystalline Corrosion of 18-8 Steel Containing Silicon and Aluminum. L. Ya. Liberman. *Kachestvennaya Stal,* No. 8, 1935. In Russian. 4 steels made in a high frequency furnace were studied. They contained 18.5-19.3% Cr, 7.8-8.8% Ni. 3 of them had 0.15% C, the fourth 0.49% C. Their Al content was respectively: 0.33, 0.86, 0.50, 0.98% and Si content: 0.69, 0.93, 2.45 and 2.12%. This corresponds to steels in which the sum of Si and Al equals to 1, 2 and 3% with the same C content and to 3% in case of high C. Low C steels were in solid solution at 1100° C. producing after quenching in water austenitic structure in the first case and austenitic-ferritic structure in the last two. High C steel was not fully in solution at 1200° C. giving a structure of austenite and carbides. Testing for strength up to 900° C. showed that for 0.15% C steels addition of Al + Si in the amounts up to 3% has but little effect on the strength, though the elongation of steel containing 1.8% of these elements is about 8% greater than the corresponding value of two others. Steel with 0.49% C has high tensile strength, but is difficult to forge. Impact values are practically constant for 3 steels with the exception of 0.15% C and 3% (Al + Si) which has a minimum at 700° C. and a maximum at 900° C. Drawing quenched steels at 600° to 800° C. showed that intercrystalline corrosion, as determined by Strauss solution, is absent in 0.15% C steels to which sufficient Al and Si was added to form a 2 phase structure. Steel containing a total of 1% of Al + Si and steel with 0.49% C and 3% Al + Si failed in solution. Heating in air at 800° and 1000° C. showed that 3% of (Al + Si) added to 18-8 steel greatly increases its resistance to scaling. An 18-8 steel containing 2.0-2.5% Si and 0.5-1.0% Al is recommended as having high strength at high temperatures and low scaling characteristics. (11b)

The Wear Resistance of White Cast Iron. O. W. Ellis, J. R. Gordon & G. S. Farnham. *Foundry Trade Journal,* Vol. 53, Dec. 19, 1935, pages 449-452. The tests were conducted in a Greey, motor-driven, 6-jar mill, designed to take end-discharge porcelain jars of standard dimensions. The jars were rotated at 60 r.p.m. The grinding medium was ¼" silicon carbide grain. Swedish wrought Fe, washed metal and West Coast hematite pig Fe formed the basis for every melt. A pouring temperature of 1500° C. was used, this being checked with an optical pyrometer. The sand cast balls were used. The following conclusions were drawn by the authors: (1) Given a suitable abrading medium, the ball mill can be used to measure the wear resistance of white cast Fe. (2) The higher the C content the less consistent are the results of wear tests on cast balls made from these materials. (3) The higher the C content of white cast Fe, other things being equal, the lower is its wear resistance under the conditions of test described. (4) Variations in amounts of Mn up to about 1% are practically without effect upon the wear resistance of white cast Fe. No benefits acrue from adding up to 6% Mn to white cast Fe containing ledeburite. (5) Increase of Si from about ¾% to about 1½% has little or no effect on the wear resistance of white cast Fe, but results in a remarkable increase in that of mottled irons. (6) S is deleterious in its effect on the wear resistance of white cast Fe. AIK (11b)

Wrought Iron, Report of Committee A-2. H. W. Faus, Chairman. *Proceedings American Society for Testing Materials,* Vol. 35, Part I, 1935, pages 70-73. Progress report on Tentative and Standard Specifications and revisions. VVK (11b)

The Properties of Some Low-Nickel Steels Containing Manganese. R. H. Greaves. *Engineering,* Vol. 140, Nov. 29, 1935, pages 593-594. From a paper read before the Iron & Steel Institute, Sept. 1935. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 32R/2. LFM (11b)

Compression Yield Point of Casing Is Increased Sharply by New Process. *Steel,* Vol. 98, Jan. 20, 1936, page 36. Outlines process of A. O. Smith Corp. for producing oil-well casing of greater strength without increased weight. Pipe with larger circumference than desired finished circumference and with proportionately thinner walls, is compressed in a 10,000-ton press, equipped with special dies, to the desired dimensions. For example, pipe originally 7" in diam., with walls 0.362" thick, was reduced to diam. of 6.562" while wall thickness increased to 0.378". Compression yield-point increased from original of 66,000 lbs./in.^{2} to 91,000 lbs./in.^{2} Collapse pressure increased from original of 5450 lbs./in.^{2} to 9150 lbs./in.^{2} Stress at collapse increased from 55,300 lbs./in.^{2} to 84,000 lbs./in.^{2} MS (11b)

Quenching Characteristics of Carbon Tool Steels. V. V. Kuznetzov & N. V. Semenov. *Kachestvennaya Stal,* No. 9, 1935, pages 16-22. In Russian. Steels were classified into deep and shallow hardening after quenching in water at 76° to 900° C. They were made in a 3 ton arc furnace. The study was directed towards the relation between the melting and deoxidation practices and the quenching properties of steel. Steels were deoxidized under a carbide slag and by adding Fe-Si, Al and FeMn. At different stages of heats spoon tests were deoxidized with different substances to study the influence of the latter on the quenching properties. These tests were forged down and quenched from the desired temperature to study their behavior. From 19 heats so produced (it is not clear whether these spoon tests were considered as heats) 17 were shallow hardening and had a wide quenching interval. It was concluded that steels with high O_2 content at the time of melting down do not quench properly after 70 minutes under carbide slags, though they might have 0.7-1.0% C. Quenchability increases with deoxidation. Deoxidation with Al gives small grain and wide range of quenching. Si and Mn action also depended on the degree of oxidation. Quenchability is dependent on the amount of deoxidizers added, time allowed after their addition, degree of slagging of oxides and temperature of the bath. This property is but little affected by subsequent heat treatment, though overheating in annealing increases quenchability of deep hardening steels. (11b)

Gray Cast Iron. John W. Bolton. *Foundry,* Vol. 63, Apr. 1935, pages 18-21, 48, 50, 53; May 1935, pages 27-30, 66; June 1935, pages 22-23, 78; July 1935, pages 21-23, 48, 50; Aug. 1935, pages 38-39, 80; Sept. 1935, pages 32-33, 84, 86; Oct. 1935, pages 36-37, 78; Nov. 1935, pages 36-37 81-82; Dec. 1935; pages 36-37, 80, 83-84. (To be continued.) Series of articles dealing with: (1) The formation and properties of steadite and graphite in cast Fe; (2) Fe-C diagrams; (3) equilibrium diagrams and process of graphitization and their theories; (4) effect of Si in gray Fe, also its effect on graphitization and physical properties, and Si-Fe; (5) effect of Mn in cast Fe; (6) effect of special elements; (7) effect of S in gray Fe and equilibrium diagram of Fe-Si system; and (8) effect of Cr. VSP (11b)

Susceptibility to Quenching and Grain Size of Saw Steel. P. Ya. Barzdain & N. N. Murzin. *Kachestvennaya Stal,* No. 8, 1935, pages 5-19. In Russian. Saws made of 0.70-0.78% C, 0.25-0.40 Mn, 0.35 max. Si, 0.20 max. Cr steel had heavy tooth breakage. 4 heats were made in basic and acid open hearth furnaces and in electric arc furnace to study the influence of the manufacturing processes on the breakage. None of the factors entering them had any influence on breakage of teeth in finished saws with the exception of Al addition to the heat which reduced it. Later 46 heats were investigated in order to bring out the relation between susceptibility to quenching and grain size and breaking of teeth. Coarse grained steels were quenched in a narrow range and were associated with failure of teeth. Fine grained steel had a wide quenching range and had a greatly reduced breaking of teeth. Best results are obtained with grain size of 6 to 8 (ASTM). Paper gives a very detailed treatment of all factors involved. (11b)

Influence of Common Alloying Elements on Properties of Steel (Influence des éléments ordinaires d'alliage sur les propriétés de l'acier) Edgar C. Bain. *Revue de Métallurgie,* Vol. 32, Nov. 1935, pages 553-561. Basic reactions of thermal treatment of alloy steels are all present in common C steels. Alloying elements change only speed and intensity of these reactions and temperatures at which they occur. The best properties at room temperature obtainable with certain sections and mass C steel samples are only moderately though definitely lower than those of the corresponding type alloy steels. The factors defining the final properties of C steel are the same as for alloy steels, but C steel has certain limitations which are eliminated by addition of alloys. Dissolving in austenite on heating before final cooling they affect profoundly speed and type of transformations and, therefore, the final structure. The lower the temperature at which transformation actually takes place, the finer the division of the carbide particles and the harder the metal. Transformation takes place rapidly at higher temperatures, and to prevent them from taking place the steel must have a certain critical speed of cooling which would carry it without transformation through the higher temperature range to about 150° C. where martensitic transformation takes place. Alloys reduce it. All alloying elements with the exception of Co which actually dissolve in austenite before quenching increase the depth of quench penetration. Grain size of austenite crystals inversely affects physical properties of heat treated steels, and alloying elements refine the grain either by formation of finely divided solid oxides in deoxidation, or by forming insoluble carbides during solidification. Deep quenching can be produced here either by adding some other element or by a partial solution of the carbide forming alloy, such as Mo. The nature of the carbides formed by alloying substances has influence both on the grain size and speed of transformation depending on their stability at higher temperatures. JDG (11b)

B. S. 3. S. 11 Steel in Aircraft Structures. P. L. Teed. *Metal Treatment,* Vol. 1, Autumn 1935, pages 135-140, 142. A detailed study of the longitudinal and tranverse mechanical properties of forged bars of various diameters of the above nickel-chromium steel, and of the influence of tempering temperature. Too high a tempering temperature causes low values of 0.1% proof stress, and it is recommended that requirements for this property should be specified. Repeated hardening and tempering had no adverse effects if done as specified, but water quenching is liable to cause cracking. JCC (11b)

The Exploits of Science in the Industries are described plainly and interestingly in a notable new popular book

A comprehensive, compact, authoritative, readable account of the recent advances, present status, and future opportunities of industrial research, as discerned at Mellon Institute.

Written especially for business and other busy men, at the request of many of them; usefully informative to all who wish to learn about the value of scientific research in creating new products and new processes and in improving present commodities and their methods of manufacture.

Industrial research, the subject of this book, is the fact-finding agency of scientific management in the industries. Its principal aims are to aid in developing technology by advancing manufacturing operations through the application of scientific methods and by discovering new materials, new processes, and new uses for products. Scientific management therefore requires and seeks the constant and full collaboration of scientific research. The very rapid progress and present strong position of industrial research are attributable to its economic soundness.

12. EFFECT OF TEMPERATURE ON METALS AND ALLOYS

L. JORDAN, SECTION EDITOR

The abstracts in this section are prepared in co-operation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M.

Modern Refining Requires Extensive Use of Alloy Steels for Equipment. H. D. NEWELL. *Oil & Gas Journal,* Vol. 34, Feb. 20, 1936, pages 32-34. In an effort to develop an alloy intermediate between 18-8 Cr-Ni and 5% Cr steel, the nominal composition was obtained of 9.25% Cr, 1.50% Mo, and .12% C and was given the trade name "Croloy 9". Tables of physical properties of 8-10 Cr steel with various additions of Mo, V, and W are given. The chosen alloy has stainless properties approaching those of 12% Cr-iron alloys and for this reason may be termed "semistainless" as contrasted to the complete stain-resisting qualities of 18-8 and the nonstainless qualities of 5% Cr steels. Tubes of this alloy are in service in many oil refineries. Some 10 commercial electric furnace heats have been processed into tubes with all indications that the alloy can be satisfactorily handled in rolling bars and in piercing and rolling tubes. As annealed, tubing has good ductility and may be readily expanded, formed or bent. In welding, practices must follow those acceptable for 5% or higher Cr steels. Susceptibility ratio tests of impact specimens show the alloy to be free from any tendency toward embrittlement when cold with excellent ductility when hot. Tubes meet the following minimum physical requirements: tensile strength 75,000 lbs./in.^{2}; yield point, 30,000 lbs./in.^{2}; elongation in 2", 30%; and Brinell hardness, 180 max. It is suitable for elevated temperature service up to about 1250° F. metal temperature in such applications as furnace tubes and heat exchanger tubes for oil refining and for superheater tubes in steam boilers. VVK (12)

Refractory Chromium Cast Irons (Les Fontes Refractaires au Chrome) PAUL BASTIEN. *Chaleur et Industrie,* Vol. 17, Jan. 1936, pages 13-14. Cr in cast Fe tends to keep C in the combined state, forms a solid solution with the Fe carbide and refines the structure. Its effect at high temperatures is to stabilize the cementite and prevent graphitisation, to raise the transformation temperatures, and to form adherent protective films. Fe with 0.5 to 0.7% Cr is practically stable at temperatures up to 800° C., and with 1-3% Cr, may be used up to 900° C. High Cr irons with up to 37% Cr, and often with additions of Si and Al are serviceable at higher temperatures. JCC (12)

The Utilisation of Creep-Test Data in Engineering Design. R. W. BAILEY. *Engineer,* Vol. 160, Dec. 6, 1935, pages 592-594; *Engineering,* Vol. 140, Nov. 29, 1935, pages 595-596; Dec. 13, 1935, pages 647-651. From a paper read before the Institution of Mechanical Engineers, Nov. 22, 1935. LFM (12)

Silicon Cast Irons (Les Fontes au Silicium) LÉON GUILLET. *Chaleur et Industrie,* Vol. 17, Jan. 1936, pages 14-15. A brief survey of the characteristics of cast Fe containing up to 15% Si. For heat-resisting service, the C and Si contents should be adjusted so that a ferritic hypoeutectic structure exists throughout the temperature range employed. Cast Fe with 6% Si and 2.8% C is satisfactory up to 950° C. JCC (12)

Behavior of Mild Steel Under Prolonged Stress at 300° C. C. H. M. JENKINS. *Iron & Coal Trades Review,* Vol. 131, Sept. 20, 1935, pages 434-435. Paper read before the Iron & Steel Institute, Sept. 1935. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 79R/5. Ha (12)

Refractory Cast Irons in the Construction of Heat Exchangers (Fontes Refractaires dans la Construction des Echangeurs Thermiques) LE THOMAS. *Chaleur et Industrie,* Vol. 16, Dec. 1935, pages 533-536. Structural changes which occur in cast Fe on heating, and the influence of added elements on these are discussed. At steady temperatures below 400° C. ordinary cast Fe corrodes appreciably less than steel; for steady temperatures up to 500° C. "pearlitic" Fe is recommended; up to 800° C., Fe with 0.5-0.7% Cr; and up to 1000° C., Fe with 1.0 up to 3.0% Cr. The latter is very fragile and will not withstand variations in temperature. For rapidly varying temperatures, or in corrosive atmospheres, 5-7% Si iron is recommended; and for particularly severe corrosive conditions low-C iron with 30-34% Cr or austenitic Ni-Cu-Cr irons are suitable. JCC (12)

Metals for Heat Exchangers (Les Materiaux Metalliques pour Echangeurs Thermiques) ALBERT PORTEVIN. *Chaleur et Industrie,* Vol. 17, Jan. 1936, pages 11-13. A brief survey of the characteristics of special steels and cast irons at high temperatures. In making a choice of materials for high temperature service, long-time tests on mechanical resistance, corrosion resistance to hot gases, and expansion through graphitisation are desirable. Short time time tests can only be used for preliminary elimination. JCC (12)

An Investigation of the Nature of Creep Under Stresses Produced by Pure Flexure. H. J. TAPSELL & A. E. JOHNSON. *Journal Institute of Metals,* Vol. 57, No. 2, 1935, pages 121-140; *Engineer,* Vol. 160, Oct. 4, 1935, page 342; *Engineering,* Vol. 140, Oct. 4, 1935, page 372. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 79R/2. LFM (12)

Scientific and Industrial Research. *Engineer,* Vol. 161, Jan. 10, 1936, pages 54-57. From the Report of the Department of Scientific & Industrial Research for the year 1934-1935 published by H. M. Stationery Office. A brief summary of research on the behavior of materials at high temperatures and on light alloys. LFM (12)

13. CORROSION AND WEAR

V. V. KENDALL, SECTION EDITOR

Determination of Corrosion on Underground Pipe Lines and Methods Used in Mitigation of Problem. G. C. GABLER & O. C. MUDD. *Oil & Gas Journal,* Vol. 34, Oct. 24, 1935, pages 54-67. Comprehensive and practical discussion with the following general conclusions. Mitigation of corrosion on underground pipe lines and structures by cathodic protection is practical. Degree to which this protection is to be carried depends upon the economic returns to be realized. Principal factors will be prevention of loss of commodities, prevention of damages, curtailment of maintenance and recovery value of equipment. Figures on which the degree of such protection are to be based will depend upon the accurate record of expenditures and observations of companies engaging in such work. Coordination of such information will also assist in establishing a sound basis for such work. Methods of providing cathodic protection are dependent upon cost and reliability. Where power from sources of mechanical generation is not available, the installation of Zn anodes offers the most practical solution to date. VVK (13)

Experiences and Developments in the Electrical Protection of Pipe Lines. STARR THAYER. *Oil & Gas Journal,* Vol. 34, Oct. 24, 1935, pages 120, 122. A general discussion of cathodic protection of pipe lines. This method of protection may be used in many instances to save heavy replacement or reconditioning expenditures. It may also be used on new lines that are not as yet producing any corrosion troubles as an insurance against trouble in the future. VVK (13)

General Consideration on Mitigation of Electrical Corrosion of Pipe Lines. VINCENT LEE NEALY. *Oil & Gas Journal,* Vol. 34, Oct. 24, 1935, pages 85-90. Detailed accounts of installations of cathodic protection on pipe lines of The Texas Pipe Line Co. Data are given on the operation of the wind-driven generating unit previously described. See "Cathodic Protection on Pipe Lines by Wind Driven Generator Unit," *Metals & Alloys,* Vol. 6, Sept. 1935, page MA 374R/8. VVK (13)

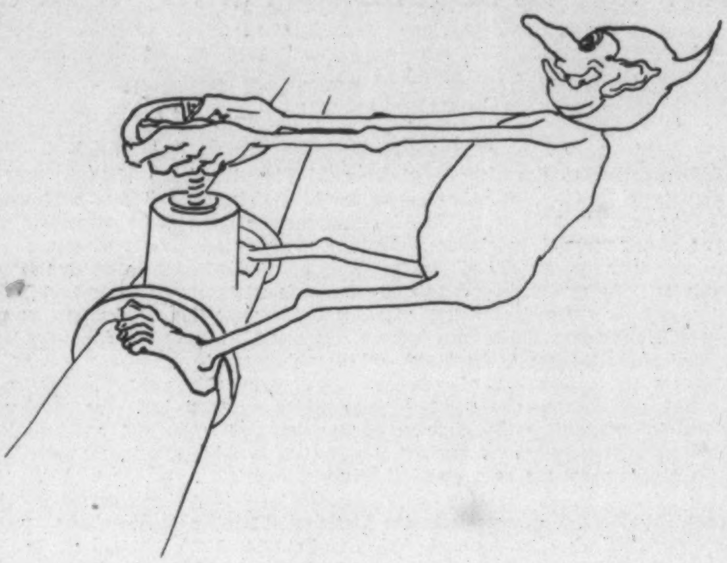
Electric Pipe Line Drainage a Practical Alternative to Reconditioning Pipe. GEO. I. RHODES. *Oil & Gas Journal,* Vol. 34, Oct. 24, 1935, pages 130-136. A comprehensive review of cathodic protection of pipe line systems from a practical and economical standpoint with particular reference to a paper by the author before the Natural Gas Department of the American Gas Association in May 1935. Data are also given showing by leak records that cathodic protection is entirely effective with a time lag of about 6 months, i.e. leaks will be entirely stopped about 6 months after cathodic protection is turned on and after it is turned off it will be 6 months before leaks will again develop. VVK (13)

Sucker Rod Failures Often Traceable to Incorrect Practices in Oil Fields. W. R. SHIMER. *Oil & Gas Journal,* Vol. 34, Sept. 5, 1935, pages 48, 50. The treatment a sucker-rod receives in the field is as important in determining the life to be expected from the rod as the manufacture of the rod itself. Rods, metallurgically correct when leaving the mill, have not given good service. The author points out various abuses such as bending or nicking in handling; not tightening a coupling sufficiently will invariably cause pin breaks; high overloads due to too quick taking up of slack, etc. Rods taken out of a bad sulphide well were so brittle that they could be broken by a light tap of a hammer; in 3 weeks the brittleness had disappeared. The author suggests if possible a periodic low anneal or heating for sucker-rods used in sulphide wells to remove brittleness. Careful observation and records of the use accorded sucker-rods in the field will solve many "mystery" failures. VVK (13)

Action of Solutions of Sodium Silicate and Sodium Hydroxide at 250° C. on Steel Under Stress. W. C. SCHROEDER & A. A. BERK. *Metals Technology,* Jan. 1936, *American Institute Mining & Metallurgical Engineers Technical Publication* No. 691, 14 pages. Special equipment was used for stressing steel specimens in aqueous solutions at 250° C. A given stress was maintained until the specimen broke or until it had been applied for from 4 to 12 days. Straub had found that in solutions of caustic soda steel failed by "caustic embrittlement." Such embrittlement was not found with C.P. NaOH. Straub had used commercial NaOH. Analysis of this material showed it to contain an appreciable amount of silicate. Tests in solutions of silicate and NaOH plus silicate indicated that the silicate was responsible for the embrittlement, which resulted in the failure of the specimens at comparatively low stresses in a few hours. Intercrystalline cracks were formed in the specimens stressed in silicate solutions. JLG (13)

Care and Preservation of Bronze Statues. WESLEY LAMBERT. *Metal Industry,* London, Vol. 47, Aug. 2, 1935, page 107. The author believes it necessary that the custodian of bronze statuary exposed to the elements have knowledge of corrosion of metals. The distinctive coloring and patina should not be maintained at the expense of the metal itself and by loss of detail. The most desirable cleansing reagents and the best remedial measures have been developed by those who are students of atmospheric corrosion and familiar with the corrosive action of the atmosphere on different metals. Water is recommended as the best cleansing reagent but very small additions of soap powder or ammonia are suggested as sometimes permissible. Extreme care is necessary to prevent staining of marble. In the study of preservation of metals coatings tested have been grouped into (1) transparent lacquers and varnishes and (2) waxes and greases. The disadvantages of the first group are indicated and it is stated that preservatives of the second group are most popular in Great Britain. A mixture of bees-wax and turpentine is the most popular. It is not permanent but when used 3 times a year is an excellent safeguard. HBG (13)

Metals in Wineries. CHARLES S. ASH. *Industrial & Engineering Chemistry,* Vol. 27, Nov. 1935, pages 1243-1244. It has been found that the ability of various metals to resist the corrosion due to hot (about 95° C.) wine and fruit juices is as follows: Cr-steel (18-8), silicon irons such as Duriron, Corrosiron, bronzes (Amberac, Tobin), Cu, Monel metal, brass, Ni, Al, Al-alloys, wrought Fe, steel, Pb, Sn, cast Fe, Zn. The results of tests with vinegar on Cr-steels and Duriron are also given. MEH (13)



A NEW BOOK ON A BIG SUBJECT IS NOW IN PRESS

CORROSION RESISTANCE OF METALS AND ALLOYS

by Robert J. McKay and Robert Worthington

ALL who have to do with metals—producers, manufacturers, distributors and users—find themselves faced with corrosion problems. This book was written primarily to povide help to a man in this situation.

The total annual loss from corrosion is tremendous. In one case the wrong use of metal led to the scrapping of several hundred thousands dollars worth of equipment inside a month or two, in another the loss was nearly as great. These losses would have been entirely avoided if one or two perfectly simple facts of corrosion had been understood. Losses on a minor scale, due to lack of understanding, are innumerable.

Corrosion can be made an extremely complicated subject. The authors have not let it become so in this book. They have taken as the basis of discussion the simple facts of what a corrosive will do to metals or how a metal will behave in the face of corrosives. Insofar as possible they have expressed this behavior in quantitative terms. Involved discussion of the theories of corrosion have been avoided, yet enough of this has been included to provide background. The approach is essentially a practical one.

Corrosion knowledge is rapidly increasing. It is believed that the present work of about 500 pages may serve for years to come as a pattern into which each newly discovered fact may be fitted and which thus may provide this fact with its true and useful interpretation.

Additions which Reduce the Attack of Solutions on Aluminum (Angriffvermindernde Zusätze zu das Aluminium angreifenden Lösungen. Addition de produits immunisants aux solutions corrodant l'aluminium) H. Röhrig. *Aluminium,* Vol. 17, Nov. 1935, pages 559-562; *Revue de Métallurgie,* Vol. 32, Nov. 1935, pages 577-580. The disintegration of Al by alkali solutions is prevented not only by additions of Na silicate (as discovered in 1929) but also by other colloidal substances such as animal and vegetable glues. As an explanation of this protective action it is assumed that the colloids deposit on the metal surface because of their electric charge. Experiments were made with nicotine and nicotine sulphate in HCl solutions, dibenzyl sulphide in HCl solutions, and several special solutions from different makers with pure Al and Al alloys; the results are shown in tables and show remarkable reductions in the amount of metal dissolved. A number of industrial and domestic applications are described. Ha + JDG (13)

Effect of Smoke on Building Materials. H. B. Meller & L. B. Sisson. *Industrial & Engineering Chemistry,* Vol. 27, Nov. 1935, pages 1309-1312. Reports and observations show continuation of excessive air pollution and resultant damage to building materials. Effects of tarry matter and S compounds resulting from combustion of fuel are discussed, complications caused by city smoke in air-conditioning, and efforts to develop materials and protective coatings more resistive to air-borne corrosive agencies are noted. It is remarked that the progress and development that is manifested by the production of such materials as stainless steels, tiles, porcelains, anodic Al finish, should be matched by the progress in air purification. Die-Cast Metals and Alloys, Report of Committee B-6. J. R. Townsend, Chairman. *Proceedings American Society for Testing Materials,* Vol. 35, Part I, 1935, pages 181-183. Progress report. **Appendix I: An Investigation of Aluminum Die-Casting Alloys Nos. IVa and Va.** E. E. Thum, Chairman. pages 184-189. Outline of an investigation of a 5% Si and a 12% Si Al die-casting alloy. Analyses and original mechanical properties are given. Subsequent reports will cover the accelerated or the atmospheric corrosion tests. **Appendix II: Report of Subcommittee V on Exposure and Corrosion tests.** W. M. Peirce, Chairman. Pages 190-226, discussion pages 227-229. This report covers the results of the first 5 years of exposure tests of 12 Al and 10 Zn alloys cast by several producers and exposed at 6 outdoor and 4 indoor locations. The general conclusion is that with the Al alloys no significant changes have been induced by corrosion and only small changes have resulted from aging. The following conclusions are drawn on the Zn alloys. The superiority of alloys prepared with high-purity Zn (99.99+%) over those prepared with high-grade Zn (99.90%) which was demonstrated in the 95° C. steam tank is confirmed by the 5-yr. exposures. The steam test causes corrosion due to the combined effect of moisture and heat and also aging changes due to the effect of heat alone. Comparison of the effects of the steam exposure, exposure to dry heat, and the various atmospheric exposures show that the results of the steam test, when properly interpreted, afford a reliable and rapid means of predicting whether intercrystalline corrosion will occur under atmospheric exposure conditions over long periods of time. VVK (13)

Corrosion of Non-Ferrous Metals and Alloys, Report of Committee B-3. T. S. Fuller, Chairman. *Proceedings American Society for Testing Materials,* Vol. 35, Part I, 1935, page 141. **Report of Subcommittee VI on Atmospheric Corrosion of Non-Ferrous Metals and Alloys.** W. H. Finkeldey, Chairman. Pages 142-159. This report presents results of the atmospheric corrosion tests on 24 non-ferrous metals and alloys after an exposure of approximately 3 years. The data on changes in weight, changes in tensile strength, and visual examination are given in the form of tables. **Report of Subcommittee VII on Corrosion in Liquids.** A. J. Phillips, Chairman. Pages 160-166. Data are reported on an 8-month sea water exposure test of 20 materials; 13 materials in NaOH; and 16 materials in H_2SO_4. **Report of Subcommittee VIII on Galvanic and Electrolytic Corrosion.** C. L. Hippensteel, Chairman. Pages 167-175. This report presents the results of dissimilar metals in contact in outdoor exposure at 9 locations after 3 years. VVK (13)

Reconditioning Natural Gas Pipe Line Without Any Interruption to Service. A. L. Forbes, Jr. *Oil & Gas Journal,* Vol. 34, Oct. 24, 1935, pages 102-103. Details of the reconditioning of the 16" natural gas line between Ysleta and Clint, Tex. which operates under a pressure of from 250 to 300 lbs. without disturbing service. VVK (13)

Corrosion of Iron and Steel, Report of Committee A-5. F. F. Farnsworth. Chairman. *Proceedings American Society for Testing Materials,* Vol. 35, Part I, 1935, pages 81-85. The Committee offers 3 new proposed tentative specifications for electrodeposited coatings: (1) of Zn on steel, (2) of Cd on steel and (3) of Ni and Cr on steel. (1) and (2) require a minimum thickness of 0.0005" Zn or Cd for general service and 0.00015" for mild service. (3) requires a minimum thickness of 0.00075" Ni or combined Ni and Cu for general service. (If Cu is used the minimum thickness of the final Ni layer should be 0.0004"). For mild service, the Ni or the combined Ni and Cu should be 0.0004" and if Cu is used, the minimum thickness of the final layer should be 0.0002". If a Cr finish is specified, the minimum thickness of the Cu and Ni layers should be as above and the average thickness of the Cr should not be less than 0.00002". The atmospheric test at Annapolis and the Key West and Portsmouth sea water immersion tests are continuing. **Report of Subcommittee VIII on Field Tests of Metallic Coatings.** R. F. Passano, Chairman. Pages 88-103. Progress report. The additional data confirm the tentative conclusions of last year, namely that at a given location the amount of protection is substantially in accord with the weight of coating and that the same weight of coating gives quite different amounts of protection at different locations. Data on the coated hardware, structural shapes, tubular goods, etc. are given in the form of tables. VVK (13)

Why Metals Corrode. R. M. BURNS. *Monthly Review American Electroplaters' Society,* Vol. 22, Nov. 1935, pages 33-46. Corrosion is defined in general terms as the chemical reaction of a metal with a non-metal. Metals corrode because it is their inherent tendency to react with non-metals with attendant liberation of energy, usually in the form of heat. Corrosion may also occur by replacement, i.e. the metal displaces H_2 from water, or other compounds, and goes into solution itself. The rusting of Fe by water or acids is an example. The original metal may also displace another metal from solution which is illustrated when Zn is placed in a solution of $CuSO_4$ and a film of Cu appears on the Zn surface. The mechanism of the above mentioned corrosion actions is electrolytic-the existence of small anodes and cathodes. Corrosion cells are set up under various conditions. Thus an annealed region of a metal may be cathodic to a strained region which will be anodic (dissolves). Other types of cells are given in a table:

Nature of Couples Comprising Corrosion Cells.

Cathode	*Anode*
Noble metal	Base metal
Oxide	Metal
Dust (carbon)	Metal
Annealed metal	Strained metal
Large metal crystal	Small metal crystal
Metal (O_2)	Metal (Absence of O_2)
Metal in high M ion concentration	Metal in low M ion concentration
Metal in high H ion concentration	Metal in low H ion concentration

GBH (13)

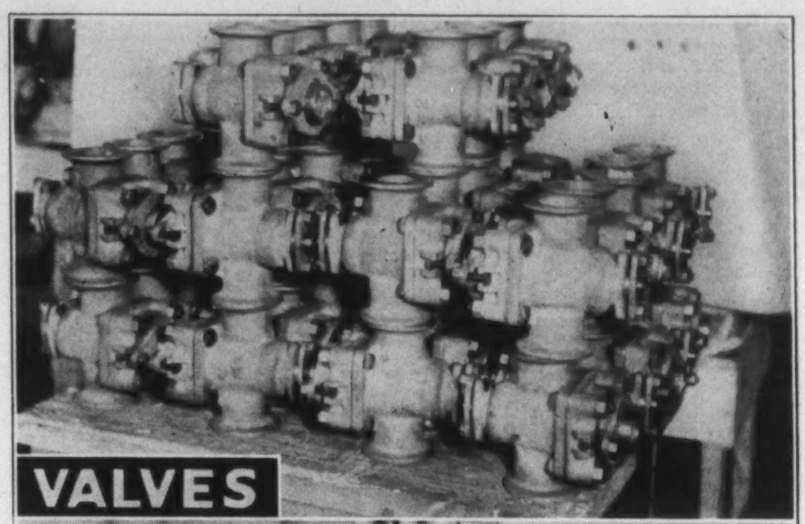
Metallic Wear. H. W. BROWNSDON. *Journal Institute of Metals,* Vol. 58, Dec. 1935, pages 535-549 (Advance Copy No. 720). A special machine for measuring wear was constructed. In this machine a rotating steel disc was pressed against the metal to be tested, the latter being in the form of a thin plate. The periphery of the disc was rounded to a radius of 0.05", the diameter of the disc being 1" and its thickness 0.1". Wear was determined by measuring the dimensions of the impression made by operation of the disc under a definite pressure for a definite time. Tests were made with plenty of lubrication, a light machine oil being used in most tests. Tests with a soap solution showed that for some alloys wear was greater with this and for others wear was greater with oil. The rate of wear depended to a large extent on whether or not the metal seized. Alloys with a duplex structure did not appear to have a higher wear resistance than other alloys. Cold working did not change the wear resistance of Cu alloys. Increasing the Sn content of Cu-Sn did not change wear resistance. JLG (13)

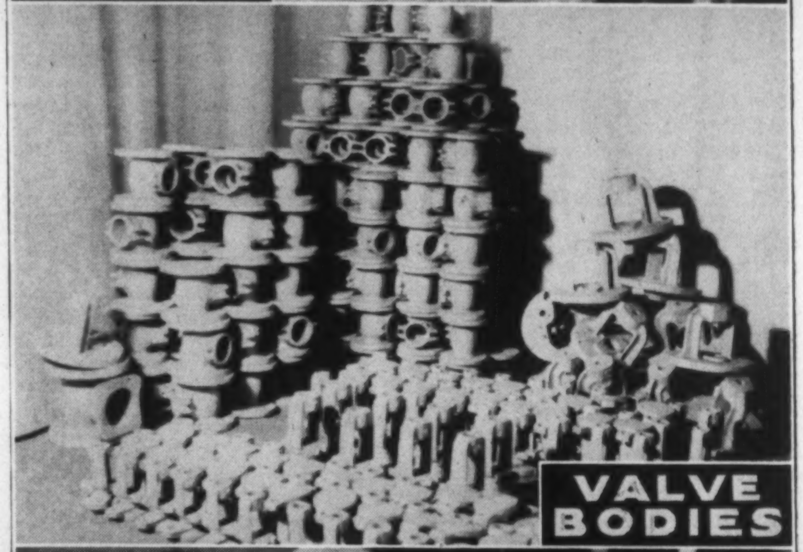
The Resistance of Galvanized Iron to Corrosion by Domestic Water Supplies. S. C. BRITTON. *Chemistry & Industry,* Vol. 55, Jan. 24, 1936, pages 19T-22T. An extensive series of laboratory experiments were made with steel and Zn (either sheet Zn or galvanized Fe) immersed in solutions containing the salts present in public H_2O supplies, having a wide range of pH values and degrees of salinity. The Zn sheet had a composition similar to galvanizing (Pb content 1%). The composition of the steel used was 0.108% C, 0.40% Mn, 0.062% S and 0.039% P. The data resulting from the tests may be briefly summarized as follows: (1) H_2O having a pH of 7.5 and 8.5, and containing $CaCO_3$, but low SO_4, Cl and NO_3 radicals is initially corrosive to Zn. The rate, however, drops to zero after a short time; Fe is evenly and progressively attacked. (2) H_2O low in $CaCO_3$ and appreciable amounts of SO_4, Cl and NO_3 radicals is both initially and progressively corrosive to Zn, evidenced by deep and preferential pitting; Fe corrodes evenly. The difference between Zn and Fe corrosion characteristics appears to be due to an insoluble and highly protective film of $CaCO_3$ which forms on the Zn, but not on Fe. The deciding factors for corrosion of Zn in the above described water supplies are, thickness of Zn deposit, $CaCO_3$ content, pH value and conductivity. AAA (13)

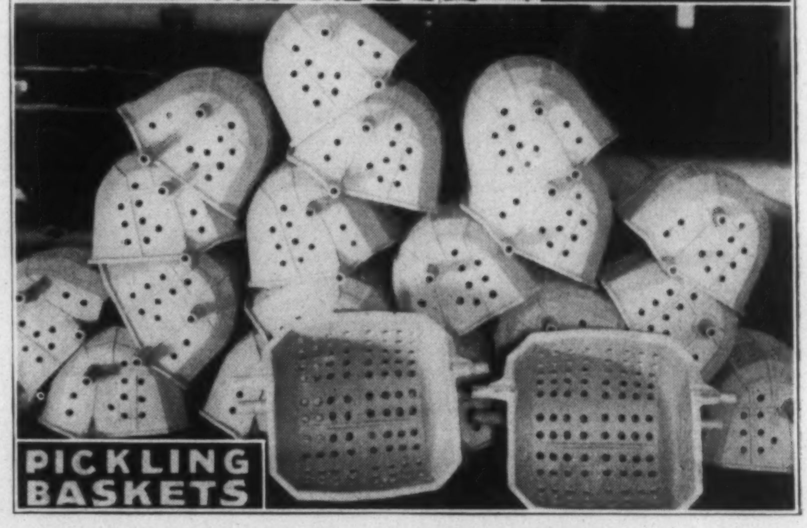
Influence of Heat Treatment on the Corrosion Resistance of Plated Duralumin (Einfluss der Wärmebehandlung auf die Korrosionsbeständigkeit von plattiertem Duralumin) P. BRENNER. *Zeitschrift für Metallkunde,* Vol. 27, Aug. 1935, pages 169-174. With discussion. Duralumin sheets of 0.5 and 1.0 mm. had an 0.03 mm. Al plate free from Cu on both sides, while 1.5 mm. sheets had an 0.05 mm. plate. These were initially in an untreated soft condition and hardened (a) by quenching in H_2O from 500° and holding at 20° for at least 5 days, (b) by air cooling from 350°, heating to 500° for 10 minutes, quenching in H_2O, and aging at 20° for at least 5 days. Micrographs showed the protective layer to be quite distinct on the original material, but after 30 minutes of treatment (b) half of the zone had vanished, and 60 minutes of type (a) caused diffusion to extend to the surface of the 0.03 mm. plates, though this zone did not disappear after 5 hrs. of (a) with 0.05 mm. plates. Accelerated corrosion tests were made at room temperature in solutions containing 3% NaCl + 0.1 H_2O_2. After various periods of exposure, measurements of tensile strength and elongation showed that resistance to corrosion was best when diffusion was the least, but that plated material was always superior to straight duralumin. Similar corrosion tests in sea water showed nearly complete resistance for all plated samples over a 2-year period. Plating was also shown to be effective for samples aged at 140°, when subjected to a salt spray test while strained. GD (13)

Questions of Rust Protection (Ueber einige Rostschutzfragen) A. V. BLOM. *Korrosion & Metallschutz,* Vol. 11, Nov. 1935, pages 245-249. Destruction of materials by corrosion, protective coatings, preparation of the surface to be protected and qualities of coatings are discussed in a general way. The protective coat should be applied only to thoroughly cleaned and perfectly dry Fe, unless bituminous emulsions are used. The ground coat should be of red lead or chromate under oil paints, and of a bituminous nature under bitumen lacquers. Directions for correct application and timing of application, and for selection of the coat are given. Ha (13)

Equipment Corrosion in Kansas Wells Is Retarded by Chemical Treatment. L. G. E. BIGNELL. *Oil & Gas Journal,* Vol. 34, Oct. 3, 1935, pages 32-35. The unusually severe corrosion problems present in producing fields of eastern and western Kansas are finding solution in the systematic application of chemicals. Wells are treated with caustic soda, Na cresylate, dichromate or chromate, alkaline solutions of tannic acid and similar organic acids or compounds such as tan bark, extracts of chestnut, oak, and the alkaline reacting solutions of Na aluminate, Na silicate and similar inorganic compounds. The object of the particular treatment may be the inhibition of corrosion, of the formation of heavy scale or both. VVK (13)







All of DURIMET

DURIMET—low carbon nickel-chromium alloy steel—is so proportioned that all minor constituents are in solid solution, with a structure as simple as ordinary 18/8. This is of vital importance for maximum corrosion resistance, mechanical strength and assurance against leakage under high pressure.

The low percentage of carbon is the major factor in obtaining the greatest resistance to corrosion.

If you have a corrosive solution in which you would like to test Durimet, a sample will be sent for experimental purposes.

Internal Corrosion of Sour Crude Oil Pipe Lines Presents Serious Problem. Walter F. Rogers. *Oil & Gas Journal,* Vol. 34, Oct. 24, 1935, pages 69-75. The handling of sour crude oil has been found to result in rapid internal corrosion of the pipe line equipment. The average service life which has been found to be obtained in handling sulphide crudes from the older Gulf Coast oil fields approaches 8 yrs. as a maximum. Internal corrosion of main trunk lines is not as rapid as that of gathering lines, but the recent development of rust holes through the interior of West Texas sour oil trunk lines show that rapid attack is occurring. Pipe line station manifolds and suction lines will have average service lives approaching 10 yrs. The internal corrosion attack can be reduced or stopped by removing either or both the H_2S or the water from the crude oil. No method for removing the H_2S economically has been found. The only practical means of handling the water so it will not result in rapid attack of gathering lines is to lay the lines at a slope so the settled water can gravitate to catch basins. For trunk lines it has been determined that certain velocities will prevent brine and bottom settlings and water from settling in the pipe. The use of these velocities will prevent internal corrosion from occurring. It is of importance that all air be kept from the sulphide-bearing oil if possible. This can best be accomplished by the use of vapor tight lease equipment and tight pipe line storage tanks. The use of oxygen free gas systems on these tanks to prevent oxygen access during breathing periods will result in lessened corrosion losses to both the pipe lines and the tank equipment. Cement lined pipe is recommended as a corrosion resistant pipe for gathering and suction lines. VVK (13)

The Corrosion of Pb Alloy Coated Steel Cylinders Used as Fire Extinguishers. W. L. Hewlett. *Chemistry & Industry,* Vol. 54, Dec. 20, 1935, pages 1094-1095. Chemical type fire extinguishers, i.e. the $NaHCO_3$-H_2SO_4 type and the foam mixture type ($NaHCO_3$, Saponin + $Al_2(SO_4)_3$), are occasionally subject to severe corrosion and frequent replacement. Corrosion appears to be confined to the interior of the cylinders which, in both types of extinguishers, consists of Pb-Sn alloy lined steel. The author is of the opinion that the salts in the water used in making the $NaHCO_3$ solution are chiefly responsible for the corrosion, which he proves by exposing ordinary C steel, Pb-Sn alloy, and C steel and Pb-Sn together in $NaHCO_3$. Amount of corrosion in each case was negligible. Although a porous Pb-Sn alloy coating accelerates iron corrosion in the beginning, the reaction subsides due to the formation of an oxy-carbonate film. The radicals Cl, SO_4, NH_3 salts and organic acids prevent film formation and accelerate corrosion. As a remedy, the following is recommended (1) the use of salt free H_2O, (2) addition of 2 oz. $Na_3PO_4.12H_2O$/gal. AAA (13)

Atmospheric Exposure Tests on Non-Ferrous Screen Wire Cloth. G. W. Quick. *Proceedings American Society for Testing Materials,* Vol. 35, Part I, 1935, pages 458-476. Report of Subcommittee IV of Committee D-14 on Screen Wire Cloth. Final results of a 9-yr. atmospheric test at 4 locations of 7 alloys (90-10 Cu-Zn; 80-20 Cu-Zn; 75-20-5 Cu-Ni-Zn; 70-30 Ni-Cu; Cu; 98-2 Cu-Sn; 95-5 Cu-Al) in the form of screen wire cloth. Tension tests were made before and after exposure. No correlation was found between the atmospheric results and accelerated tests in salt spray, dilute H_2SO_4 and in NaCl. The severest damage to each material was caused by the heavy industrial atmosphere at Pittsburgh. In the mildly corrosive atmosphere at Washington, no failures occurred in any of the materials during the entire period. In the temperate and tropical seacoast atmospheres of Portsmouth and Cristobal with some industrial contamination at both exposure stations, there was more damage to each material than at Washington. No conclusions aside from tables and charts are drawn as to the relative corrodibility of the materials. However the 98-2 Cu-Sn and Cu (unalloyed) lost the least in tensile strength and the 70-30 Cu-Ni, 80-20 Cu-Zn, and 95-5 Cu-Al alloys lost the most in tensile strength at most of the locations. See also *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 34L/6. VVK (13)

Pipe Cleaning. Charles Haydock. *Journal American Water Works Association,* Vol. 27, Nov. 1935, pages 1566-1571. Discussion of the cleaning of tuberculated water mains. VVK (13)

Progress in Corrosion- and Heat-resisting Steels. W. H. Hatfield. *Metallurgia,* Vol. 13, Dec. 1935, pages 41-44. Reviews development and uses of these alloys. All alloys discussed contain Cr. JLG (13)

Corrosion and Water are Problems at Rincon Plant. *Refiner & Natural Gasoline Manufacturer,* Vol. 14, July 1935, pages 357-358. A very corrosive water was successfully treated with lime-soda-sodium aluminate. Pipe lines in very corrosive soil were coated with 4 coats of pipe line grease and grease saturated wrappers. No further trouble was encountered. VVK (13)

Report of Committee on Electrolysis and Electrical Interference. N. S. Hill Jr., Chairman. *Journal American Water Works Association,* Vol. 27, Nov. 1935, pages 1581-1588. The committee recommended that the American Water Works Association revoke and rescind any and all previous approval or sanction of the practice of grounding electric light and power circuit on water pipes for protective or other purposes. The recommendation was adopted. The committee pointed out that sufficient currents were carried by the water pipes to constitute a hazard. VVK (13)

Surface Preparation and Painting of Magnesium Alloys. A. W. Winston, J. B. Reid & W. H. Gross. *Industrial & Engineering Chemistry,* Vol. 27, Nov. 1935, pages 1333-1337. Paint adhesion and protection against sea water are the main problems in connection with the painting of Mg-alloys. Pretreatment of the metal surface by chemical means such as a short dip in sulphuric acid-sodium dichromate solution, is recommended. The effect of the composition of the primer and finish coats on adhesion and protection is discussed. Tables of data are given showing the relationship between alloy, condition of chrome-pickle solution, coating, and paint adhesion. 14 references. MEH (13)

Permanent Pipe Line Reconditioning Plant Utilizes Heat and Sand Blast. Neil Williams. *Oil & Gas Journal,* Vol. 34, Nov. 28, 1935, pages 28-32. Description of the sand blast equipment of the central reconditioning plant of the Houston Pipe Line Co. at Edna, Texas. VVK (13)

New Practices Used in Pipe Conditioning to Combat Corrosion. Neil Williams. *Oil & Gas Journal,* Vol. 34, June 20, 1935, pages 14, 42. The pipe coating practice of the Houston Pipe Line Co. is described, particularly the "holiday detector" in use. VVK (13)

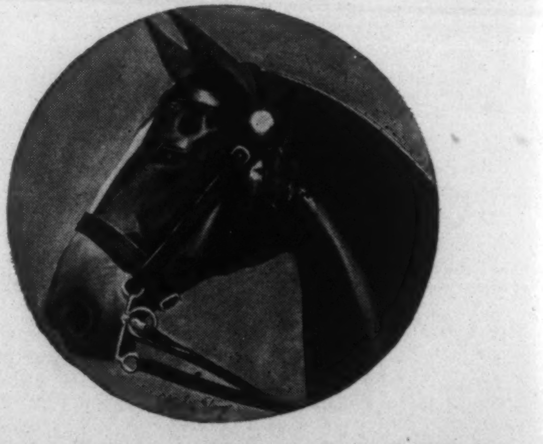
Heat Resisting Cast Irons. Albert Portevin. *Metal Progress,* Vol. 28, Dec. 1935, pages 67-68. Transfer of the principles regarding alloy additions to steel to achieve oxidation resistance, to cast iron is complicated by graphitization with expansion in volume and internal cracks from inequalities in this action and penetration of hot gases into these cracks. In order to control these factors (1) suppress graphitization by addition of carbide stabilizing alloys (Cr, Mn, W, Mo, or V) or completely graphitize by additions of Si, Ti, or Ni; (2) make additions (Al, Si, or Cr) to render completely ferritic over the range of operating temperatures; (3) improve oxidation and sulphurization resistance by additions of elements producing adhesive films (Cr, Al, Si, and Zr) and avoid elements causing intergranular decay (Ni in S atmosphere). Such irons fall into two classes: (1) 35-40% Cr (with additions of Si, Al and Zr) to produce a ferritic or carbide cast iron, (2) Si, Al, or Si-Al cast iron which are ferritic and graphitic in structure. Castibility test can be used for control of Si content which should be slightly hypoeutectic at 5.5% Si. Al irons have poor mechanical properties. Al-Si combination is 6.5-7.0% Al with 5.0-6.0% Si and 1.80-1.90% C, a difficult range to hit in foundry practice. WLC (13)

Action of Dilute Acids on Aluminum. Charles F. Poe, R. M. Warnock & A. P. Wyss. *Industrial & Engineering Chemistry,* Vol. 27, Dec. 1935, pages 1505-1507. The loss in weight of a very pure sheet Al was determined for various inorganic and organic acids, about 30 in all, at concentrations of 1.0, 0.1, and 0.01 normal, and 25° C. One set of tests was made with 0.1 normal acids boiled for 30 min. daily. All immersions continued for 12 weeks, and the loss in weight is recorded for 2, 4, 6, 8, and 12 weeks' immersion. 19 references. MEH (13)

Continuous-flow Corrosion Tests of Steel Pipe. H. S. Rawdon & L. J. Waldron. *Proceedings American Society for Testing Materials,* Vol. 35, Part II, 1935, pages 233-248; *Engineering,* Vol. 140, Aug. 23, 1935, pages 208-209. See *Metals & Alloys,* Vol. 6, Jan. 1936, page MA 36L/5. LFM (13)

Reconditioning Water Supply Lines with Bituminous Enamel. Linden Stuart. *Journal American Water Works Association,* Vol. 27, Aug. 1935, pages 1055-1064. Review of the reconditioning of water mains. The coating advocated is a compounded coal tar pitch base coating of at least 1/16" thickness. Advantages are given. VVK (13)

Present-Day Maintenance of a Pipe Line System Calls for Efficiency. J. Campbell Stirling. *Oil & Gas Journal,* Vol. 34, Oct. 24, 1935, pages 91-95. The history and experiences of the Stanolind Pipe Line Co. in reconditioning their pipe lines are given. In general it is more economical to maintain pipe lines by a systematic plan than to neglect them and postpone the maintenance work through the use of temporary repairs. Extensive reconditioning on field gathering lines, on lines smaller than 6" in size or on lines of only a short economic life is not done. Smaller lines extending across salt water drains, slush ponds, and the like are protected by supporting the lines on props across such corrosive areas. VVK (13)



Down here in Maryland where
THE HORSE IS KING

FLYING hoofs roll out a fast tattoo that quickens the pulse of the wildly cheering throng on tip-toe in its excitement. Maryland's racing season is on! —and your home in Baltimore is ready for you.

Your car is taken at the door by an expert garage attendant. Yours is one of 700 comfortable rooms—each with bath or shower, running ice water, full length mirror and bed head reading lamp. You're at the center of Baltimore's business and social activities. You enjoy characteristic Maryland cuisine in any of three distinct restaurants. And the rate—from $3.00 single.

Stainless Steel, Nickel, and Nickel Alloys Solve Food Equipment Fabricator's Problems. G. H. Tay. *Food Industries,* Vol. 8, Feb. 1936, pages 60-61. Describes the use of stainless steel (18-8), Ni and Ni alloys (Monel) for equipment for processing. Stainless steel is preferred for fruit and acid products and Ni or Ni alloys for brine. Specifications are given for the construction of plain and jacketed tanks and kettles. IW (14)

How to Select Electric Heating Alloys. F. P. Peters. *Product Engineering,* Vol. 7, Jan. 1936, pages 19-21. Electric resistance alloys for heating purposes must possess high melting point, resistance to oxidation, resistance to growth, low cost, strength at elevated temperature, high electrical resistance, and low temperature coefficient of expansion. Properties of the following metals and alloys are tabulated: Mo, Pt, 80Pt 20Rh, 72Fe 20Cr 5Al 3Co, 68Fe 27Cr 5Al, 80Fe 15Cr 5Al, 80Ni 20Cr, 60Ni 16Cr 24Fe, 30Ni 20Cr 50Fe, 45Ni 55Cu, 25Ni 75Fe, 18Ni 60Cu 22Zn, ranging in melting temperatures from 4750° to 2000° F. Ha (14)

Metals in Airplanes. *Engineering & Mining Journal,* Vol. 136, Nov. 1935, page 557. Metals and alloys employed in airplane construction are listed. WHB (14)

Arc Is Discharged in Line Form in Contactor of New Design. *Steel,* Vol. 97, Sept. 23, 1935, pages 44, 46. Contactor described utilizes Al alloys in moving parts and high permeability, rolled steel armature plates and core in magnetic circuit. Contacts are cold formed of pure Cu, hardened by a special process. Nitralloy is used for bearing pins, bushings, and main contactor arm. Ag is used for stationary control circuit contacts on panel and for control circuit contacts carried on a P-bronze, double-break bridge. MS (14)

Manufacture of Fare Boxes Provides Outlet for 150 Tons of Steel Annually. *Steel,* Vol. 97, Dec. 23, 1935, page 38. Describes several types of fare boxes used on street-cars and buses. Steel, Al, and brass are chief metals used in their construction. MS (14)

G. L. CRAIG, SECTION EDITOR

Makes Large Lantern for Boulder Dam of Aluminum Castings. *Foundry,* Vol. 63, Oct. 1935, page 51. Describes lantern made of Al by the Pacific Brass Foundry. Castings are made from Al-Si alloy, similar to S.A.E. No. 35 or Aluminum Co. of America No. 43. Only new metal was used in the mixture to conform to stringent government regulations. Item of interest is the construction of the flasks, the ends of which were made to conform to irregular parting line of particular piece, resulting in one side of drag and cope being 8″ higher or lower than opposite side. VSP (14a)

Copper Channel Bus-Bars. G. W. Preston. *Electrical Review,* Vol. 118, Jan. 31, 1936, page 160. Describes use at Boulder Dam. Each phase conductor of bus-bars is composed of 2-6″ Cu channels, held together to form a hollow square by means of Cu clamps and bolts. Clamps are made from extruded sections and are fixed at short intervals along the channels. Bars and their insulators support surrounding housing. Inclosure and inter-phase barriers are constructed of ⅛″ thick Cu sheet and all fittings, nuts, bolts, and structural members are made entirely of Cu or its alloys. Required 112 tons of Cu and alloys. MS (14a)

The Electrochemical Behavior of Lead, Lead-Antimony, and Lead-Calcium Alloys in Storage Cells. H. E. Haring & U. B. Thomas. *Paper, Electrochemical Society,* Oct. 1935, pages 163-177. In the usual Pb-Sb grids Sb is leached out of the positive electrode and deposited on the negative, causing local action and self-discharge. Grids made from a Pb-Ca alloy (.1% Ca or less) do not have this defect since Ca is electronegative to Pb. In addition the Pb-Ca alloy does not sulphate so rapidly and retains its charge longer. GBH (14a)

Some Physical and Metallurgical Properties of Lead Calcium Alloys for Storage Cell Grids and Plates. E. E. Schumacher & G. S. Phipps. *Paper, Electrochemical Society,* Oct. 1935, pages 155-162. A Pb-Ca alloy containing .10% Ca has a tensile strength of 8,000 lbs./in.^{2}, which is comparable to Pb-Sb alloy now used. Pb-Ca alloy requires aging for a week at room temperature and heat treatment at 100° C. for 18 hrs. Material cost of these alloys, however, will be lower than that of Pb-Sb alloys. GBH (14a)

Sweep-Float Made Portable Through Use of Aluminum Alloy. Vernon H. Donaldson. *Engineering-News-Record,* Vol. 116, Jan. 9, 1936, pages 50-51. Sweep-float for quick checking of depths in navigable channels was built of Al in small units so that the apparatus could be taken apart and loaded on a truck for movement from port to port. CBJ (14a)

Recent Developments in the Manufacture and Applications of Magnesium and Magnesium Alloys. W. C. Devereux. *Metallurgia,* Vol. 13, Dec. 1935, pages 47-49. It is reported that Mg is now produced in England and in Austria by reduction of MgO with C in an arc furnace in H atmosphere. The crude metal is purified by distillation in an inert atmosphere. Casting and working of Mg are described. Properties of alloys are given and uses of alloys, principally in aircrafts, are mentioned. JLG (14a)

Bearing Bronzes. Published by Copper Development Association, London, 1935. Boards, 4 x 7 inches, 32 pages.

This was issued as C.D.A. publication No. 15 and discusses: requirements of a bearing metal; range of British bearing bronzes; properties of Cu-Sn bearing bronzes; bearing brasses; Cu-Pb bearing alloys; typical bearing bronzes, etc. Richard Rimbach (14a) -B-

Bearing Metals. R. T. Rolfe. *Metal Industry,* London, Vol. 46, June 28, 1935, pages 691-694; Vol. 47, July 12, 1935, pages 33-36; July 19, 1935, pages 59-62; July 26, 1935, pages 85-88; Aug. 2, 1935, pages 109-111; Aug. 9, 1935, pages 135-138. A slightly condensed version of a paper presented to the Midland Metallurgical Societies. In spite of the importance of bearings in engineering, the average engineer seems to know but little about the composition and behavior of the materials used in bearings and about lubrication in general. The author endeavors to indicate in which directions more information may be obtained. Lubrication is discussed in a broad general manner. Little information is available relative to variations in operating conditions of bearings in service due to the difficulties encountered in the determination and interpretation of data. Most bearing failures are attributed to metallic contacts caused by failure of the oil system to function properly. The requirements of good bearing metals discussed are: (1) good melting and casting properties, (2) high compressive and tensile strength under service conditions, (3) sufficient plasticity to accommodate inequalities in alignment, (4) a low coefficient of friction, (5) a high thermal conductivity, (6) a high resistance to wear. A survey is made of the materials used commercially today as bearings and it is pointed out that cost is a major factor. The constituents of the Sn-base alloys are discussed. The properties of a number of bearings, gradually changing from the Sn-base to the Pb-base are tabulated with specific recommendations indicating where each is superior. In a detailed comparison between Sn-base and Pb-base bearing alloys, the author discusses physical properties, rate of wear, conditions for lining bearings, commercial practice and practical procedure in lining, preparation before tinning and the tinning operation, lining and some specific methods used in lining. The advantages of the centrifugal lining process are indicated and the process is briefly described. Specific examples are given of bearings that failed in service and reasons why these failures are ascribed to certain factors are indicated. Among the Pb-base alloys considered are the Pb-Sb alloys and the Pb-alkaline earth alloys. The latter were developed due to the scarcity of Sn during the War. The excellent physical properties obtained with these alloys should make them economical substitutes for the expensive Sn-base alloys but the oxidation during melting and the removal of the hardening constituents as dross, will probably prevent such a substitution in normal times. Among the Cu-Sn alloys considered are admiralty gunmetal and the phosphor-bronzes. The constitutional diagram of the former is discussed, methods for obtaining the δ-constituent are indicated, some commercial applications are cited, and it is emphasized that to insure satisfactory operation of bearings of this alloy they must be accurately bored and properly aligned. Cast material is superior to hot-rolled. The advantages of phosphor-bronzes over gunmetal are pointed out and commercial applications are noted. Best physical properties are obtained when the alloy is centrifugally cast. Leaded bronzes are compared with the Cu-Pb alloys. Pb-segregation is encountered in both types of alloys but under suitable conditions 30% Pb can be used in Cu-Pb alloys without undue segregation. The additions of small amounts of S and Si-Zr have entirely prevented segregation in Cu-Pb alloys containing 40% Pb. After comparing mechanical quality, hardness and frictional quality, thermal quality, and rate of wear of leaded bronzes and Cu-Pb alloys with white metals, the author states that the straight Cu-Pb alloys are replacing the white metals where service reliability is of major importance. Self-lubricating alloys such as "Genelite," manufactured by the General Electric Co., and "Oilite," produced by the Manganese Brass and Bronze Co., are briefly discussed. The patented processes of the General Motors Co. for the manufacture of similar alloys are outlined. Included among the non-metallic bearing materials are Lignum Vitae, rubber and plastic or synthetic resins. The latter have just recently come into use as materials for bearings. Little information is, as yet, available for these materials but it is claimed that as bearings for rolling mills they are superior to either cast Fe or gunmetal. The physical properties of a number of the alloys discussed are presented in tabular form and the articles are illustrated by a number of micrographs. HBG (14a)

M. GENSAMER, SECTION EDITOR

Selection of Die Steels for Plastic Molding. *Steel,* Vol. 97, Nov. 18, 1935, pages 30-33. Principal qualities desired in die steels for plastic molding are resistance to abrasive wear and corrosion, workability, proper surfacing, and ability of core to stand up under repeated applications of pressure. There is no unanimity as to what is the most suitable all-around steel. In general, tool-steel, machine, low-C alloy, and nitralloy steels are used for this purpose. Advantages and disadvantages of each of these groups and of Cr plating molds are presented. Recently introduced steel for molding Bakelite is "Bakadie," a Ni-Mo steel with low-C. It takes a high mirror finish, has a tough core, and after heat treatment shows a surface hardness of 63-65 Rockwell. Heat treatment involves normalizing at 1150° F. between hobbing operations and cooling in still air. Die should be held for 1 hr./in.^{2} cross-section. It should be carburized at 1600°-1650° F., cooled in pot, reheated to 1475°-1550° F., quenched in oil, and drawn at 300°-400° F. Mold used in production of Plaskon housing for Toledo scale weighs 7 tons and required special methods of handling during treatment to avoid distortion, cracking, or nicking. Parts were packed with carburizer in specially constructed boxes, which were loaded into a gas-fired furnace at 1120° F. Temperature was raised in 10 hrs. to 1660° F. and held for 20 hrs. Parts were furnace cooled in 4 hrs. to 1000° F. at which they were held for 1 hr., slowly heated to 1500° F. and held for 9 hrs., quenched in oil to 400° F., cooled in air, drawn in an electric furnace held at 425° F. for 16 hrs., and air cooled to room temperature. MS (14b)

Cold Heading Dies and Die Steels. J. C. Alexander. *Mechanical World & Engineering Record,* Vol. 48, Nov. 1, 1935, pages 423-424. Cold-heading machines are now ahead of tool steels and die developments with the result that modern machines cannot always be run at maximum speed. The problem is discussed and an explanation is given of the best ways of making use of available materials. WH (14b)

Steels for Ball Bearings. B. M. Suslov. *Metal Progress,* Vol. 28, Dec. 1935, page 51. Data on steel compositions and production of ball and roller bearings in U.S.S.R. WLC (14b)

Metallurgical Developments and the Mining Industry. L. Sanderson. *Canadian Mining Journal,* Vol. 56, Nov. 1935, pages 526-527. A brief review of metallurgical developments during the past year. Mn steels, the welding of high-Mn steels, highly-alloyed cast irons, alloy steels, stainless steels and wires, Ni-Mo, Mn-Mo and special C steels are discussed. WHB (14b)

Some Mechanical and Metallurgical Aspects of Present-day Oil-production Equipment. Albert G. Zima. *Transactions American Institute of Mining & Metallurgical Engineers,* Vol. 117, 1935, pages 399-412. See *Metals & Alloys,* Vol. 6, Dec. 1935, page MA 516R/2. (14b)

The Qualities, Characteristics, and Uses of Steels. A. C. Harris. *Iron & Coal Trades Review,* Vol. 131, Nov. 29, 1935, pages 905-906. The various types of steel made in the open-hearth process used for rails, wires, structural and other industrial purposes, and the special requirements for certain purposes such as aircraft and automobile engineering are reviewed exhaustively. Ha (14b)

Iron and Steel. *Food Industries,* Vol. 7, Dec. 1935, page 576. Fe and steel in contact with foods should be protected by a non-corrosive coating. Cast Fe may be used sometimes without a protective coating because of its natural Si-Fe alloy surface but machined or ground surfaces are not so protected. Fe and steel continue to be chief metallic materials of construction for the food processor because of low cost, strength, ease of fabrication and availability. BWG (14b)

Material Problem of High-grade Rails (Zur Baustofffrage hochwertiger Schienen). Berchtenbreiter. *Organ für die Fortschritte des Eisenbahnwesens,* Vol. 90, July 1, 1935, pages 232-235. Discusses tensile strength, impact strength, wear resistance and cleanliness of rail steel. States that higher Mn and Si contents with low additions of Cr and Cu furnish tough rails of medium tensile strength but with considerably increased resistance to abrasion. Austenitic Mn steels become sufficiently surface hardened in service. Cleaner steels are obtained in electrical furnaces. Attention is called to compound rails whose rail surface has a hardness of 330-400 Brinell, while web and lower flange show 120-140 Brinell. Surface hardening by heat treatment followed by quenching, welding and built-up welding of rails are dealt with. EF (14b)

The Use of Alloy Steels in Mining Work. L. Lahoussay. *Iron & Coal Trades Review,* Vol. 131, Dec. 6, 1935, page 941. A review of the types of steel used and economies obtained in using these steels of greater strength in ropes and mine equipment, particularly in French mines. Ha (14b)

Reinforced Concrete. Report of the Building Research Board. *Iron & Coal Trades Review,* Vol. 131, Nov. 22, 1935, page 870. Comparative tests for various steels in reinforced concrete are described. Results showed that with regard to deflection and cracking due to strain, concrete reinforced with special alloy steels behaves in much the same way as with ordinary mild steel. At 12 tons/in.^{2} the deflections of the beams with special steel reinforcement were about 40-50% greater than the deflections of beams reinforced with ordinary steel at 9 tons/in.^{2} A marked increase in ultimate strength was, however, observed for the special steel reinforcement. The factor of safety was 2.67 at 12 tons against 2.33 for the ordinary steel at 8 tons/in.^{2} The tests are described and discussed in detail. Ha (14b)

Large Uses of Steel in Small Ways. No. 295. Skylight Guards. *Steel,* Vol. 97, Sept. 16, 1935, page 31. Manufacture of skylight guards requires annually about 100 tons of steel, consisting almost entirely of wire, rods and shapes. MS (14b)

Metal Replaces Glass in Radio Tubes. *Metal Progress,* Vol. 28, Dec. 1935, pages 32-37. Describes the development of metal parts in the internal structure of radio tubes and the final development of metal envelopes to replace glass. WLC (14b)

Large Uses of Steel in Small Ways. No. 296. Barber Shop Equipment. *Steel,* Vol. 97, Sept. 30, 1935, page 36. Modern barber and beauty shop furnishings represent an important outlet for Fe and steel much of which is porcelain enameled and Cr plated. About 90% of the weight of a barber chair is cast Fe. It is estimated that before the depression, more than 3000 tons of Fe and steel were consumed annually in manufacture of barber chairs. MS (14b)

Large Uses of Steel in Small Ways. No. 294. Wire Tying Machines. *Steel,* Vol. 97, Sept. 2, 1935, page 58. Machines for tying and reinforcing various articles, bundles, and cases are made in various sizes. They are made of castings, forgings, and rolled steel parts. About 6000 tons of steel wire are consumed annually for tying. MS (14b)

One-Piece Cast Steel Decks on Air Compressors Withstand Severe Service. *Steel,* Vol. 97, Sept. 2, 1935, pages 53-54. One-piece steel castings made from a special grade of low-C, unannealed steel have been found most satisfactory for withstanding shock and vibration and eliminating distortion of frames. MS (14b)

Rotary Cutter Has Liquid Seals and Saves Power by Using Roller Bearings. *Steel,* Vol. 97, Sept. 2, 1935, page 42. Describes improved cutter, utilizing steel and gray-Fe and semi-steel castings in its construction. Knives are made with special alloy soft steel backing, with high-speed steel inlays, welded together under hydraulic pressure. MS (14b)

Frameless Steel Building Erected to House Unattended Telephone Exchange. *Steel,* Vol. 97, Sept. 16, 1935, pages 38-39. Describes building constructed of steel sheets. Outer walls are porcelain enameled. Sections are shop fabricated. MS (14b)

Large Uses of Steel in Small Ways. No. 300. Car Movers. *Steel,* Vol. 97, Nov. 25, 1935, page 42. Shoe, socket, and saddle toggle of car mover illustrated are electric furnace, normalized steel castings containing 0.25-0.35% C, 0.60-0.80% Mn, and less than 0.04% in both P and S. Spur plate is of malleable Fe. Bolts, nuts, and pin are of mild steel. Roller is a steel bushing. Spurs are of tool-steel. MS (14b)

RICHARD RIMBACH, SECTION EDITOR

Metallurgical Researches of the National Physical and Technical Institute for 1934 (Aus den metallkundlichen Arbeiten der Physikalisch-Technischen Reichsanstalt im Jahre 1934). A. Schulze. *Zeitschrift für Metallkunde,* Vol. 27, June 1935, pages 139-140. A progress report of investigations on the chemical and physical properties of metals and alloys, dealing especially with the preparation of high purity materials; magnetic, thermal, and elastic properties; low temperature work; and the development of special apparatus. GD (15)

Technical Progress Provides Stimulus for Modernization of Equipment. N. G. Symonds. *Steel,* Vol. 97, Sept. 23, 1935, pages 66, 68. Discusses promotion of modernization in the steel industry by more efficacious electrical devices and mechanical improvements, with examples of developments by Westinghouse Electric & Mfg. Co. These include an automatic circuit-breaker; an "electrical drive shaft" or synchro-tie; photo-electric tube control of motor-driven sheet catcher; Micarta bearings; and gear motor. MS (15)

French Tool Steels. Albert Portevin. *Metal Progress,* Vol. 28, Sept. 1935, page 61. Brief summary of compositions of commonly used tool steels of France. WLC (15)

This Apprentice System Was Depression-Proof. Franklin R. Hoadley. *Steel,* Vol. 97, Dec. 2, 1935, pages 17-18. Paper read before National Founders' Association. Describes system of Farrel-Birmingham Co., Ansonia, Conn., for training foundry apprentices. Features include giving boy a job at 40-45 cents per hr.; guaranteeing him steady work, and regular wage increases during apprenticeship; training him in foundry practice; and offering him an opportunity for further education and advancement. MS (15)

15a. Economic

The World's Gold Resources. A. Knopf. *Scientific Monthly,* Vol. 42, Jan. 1936, pages 62-67. Present state of production, mode of occurrence of Au and the resources of the U. S. are reviewed. The Au resources of the world are very large but they cannot be measured with any approach to accuracy. Au in sea water is contained in the ratio of about 1 to 10^8 so that no commercial possibility of exploiting it can be foreseen; the deep-sea sediments, however, will very likely be rich in Au. 6 references. Ha (15a)

Recent Trends in British Iron and Steel Production. K. R. Binks. *Metallurgia,* Vol. 13, Dec. 1935, pages 67-68. Production of steel ingots in 1935 approached prosperity levels. The average output per month was 809,712 tons in 1917, 804,600 tons in 1929, and 802,255 tons in 1935. It is concluded that the causes leading to such expansion in output cannot be called abnormal, but are the result of general increase in national prosperity, protection of home markets from outside influences, and a rational policy for the regulation of the steel industry as a whole. JLG (15a)

How Can the Metal Founder Increase His Competitiveness? (Wie kann der Metallgiesser seine Wettbewerbsfähigkeit erhöhen?). Erich Becker. *Giesserei,* Vol. 22, Nov. 22, 1935, pages 586-588. The various methods of producing metallic parts, by casting, punching, turning and pressing are briefly compared and casting methods discussed at greater length as casting has the least and cheapest waste and therefore the least economical loss. Hot-pressing is sometimes advantageous especially if later the parts have to be polished. Dies for pressing should be of a composition Ni-Cr-cast Fe: 2.7-3% total C, 0.7-0.8% Si, 0.6-0.9% Mn, 2-2.5% Ni, 0.9-1.1% Cr; P should not exceed 0.2% and S 0.12%; heated to 790° C., quenched in water or oil, and annealed in boiling water to release interior stresses. Polishing methods are discussed as to their economical preferences. Ha (15a)

The Aluminum Industry. Prospects in the World Markets. Richard Flint. *Metal Industry,* London, Vol. 47, July 26, 1935, pages 79-80. The international aluminum industry has successfully endeavored to balance the world supply and demand by regulation of production and storage of the surplus output. At present Japan, Russia, and Sweden are in a state of transition from buyers to producers and British India is a new possible source. The activities in Japan and Russia, and the consequences of transition are discussed. The percentages imported and exported. the results of this transition and its effect on the domestic market are considered. HBG (15a)

The World's Metal Production and Consumption in 1934. *Engineer,* Vol. 160, Sept. 6, 1935, pages 249-250. Gives figures collected and issued annually by the Metall-Gesellschaft of Frankfurt-on-Main, Germany. From 1929 to 1932 metal production exceeded the consumption but during 1933 and 1934 the consumption increased and exceeded the production. Figures are given of world production and consumption of Pb, Cu, Zn, Sn and Al from 1929 to 1934 inclusive. American production has fallen behind the average of the whole world while that of Continental Europe has been increasing due to the expansion of the Dutch and Belgian industries from their colonial ores. Production in the British Empire of Pb, Cu and Zn increased during the past year. LFM (15a)

Dumping and the Pretoria Steel Works. *Engineer,* Vol. 160, Sept. 20, 1935, page 304. Comments on a recent complaint made by the South Africa Iron and Steel Industrial Corporation. The Pretoria works of the company which started last year have been forced to close their rolling mills for 2 weeks due to dumping of iron and steel products in the Union. It is expected that the Government will intervene in some manner to protect them although at the present time the company has an advantage over imported products through a saving of sea freight and coast charges. LFM (15a)

Russian Steel Exports. *Engineer,* Vol. 160, Sept. 20, 1935, page 302. Russia is exporting foundry iron to certain European countries and steel to Turkey. Production of Soviet pig iron in 1934 was 10.5 million tons and in 1933, 7.2 millions; 9.6 million tons of steel in 1934 and 6.9 million tons in 1933; 6.69 million tons of rolled products in 1934 and 4.48 million tons in 1933. The plan for 1935 is to produce 12.5 million tons of pig iron, 11.8 million tons of steel, 8.65 million tons of rolled products. Building and construction plans which include the entire rebuilding of the city of Moscow and extension and renewal of railways are expected to absorb the rolled products. Foreign markets are being sought for the pig iron and steel. It is thought that Russia may join the Continental Steel Cartel to secure a favorable export quota. LFM (15a)

Age of Alloys Is Upsetting Steel as a Barometer. KENNETH B. LEWIS. *Steel,* Vol. 97, Nov. 11, 1935, pages 17-18. Technical developments in the steel industry during the past 20 years, such as electric melting, alloy steels, fusion welding, and improved protective coatings, have shifted emphasis from quantity to quality. These advances have affected production curves much more than have wars, depressions, and political conditions. During the active phase of such revolution ordinary charts of steel production no longer have any clear significance as indexes of trade activity or of changes in material well-being. MS (15a)

The Progress of Magnesium Industry in Japan. S. IMATOMI. *Scientific Papers Institute of Physical & Chemical Research, Tokyo,* Vol. 27/28, Sept. 1935, pages 57-67. In English. Discusses the subject under the following headings: (1) Introduction, (2) history of the Mg industry in Japan, (3) raw materials, (4) comparison of Mg raw materials in the world, (5) methods of manufacturing Mg, (6) Mg alloys, (7) casting method and anti-corrosion methods, (8) Japan's Mg industry in future. The great supply of raw materials in Japan compared with the rest of the world is stressed and hope is expressed that Japan will become the "largest Mg producer in the near future." Ways are pointed out which will result in a lowering of present production costs. WH (15a)

Melts Iron In Air Furnaces. *Foundry,* July 1935, pages 18-20, 44, 47; **Hardens Steel Roll Surfaces.** Aug. 1935, pages 36-37, 77-78; **Makes Corrugated Slag Ladles.** Sept. 1935, pages 38-39, 96, 99. Describes the work of Mackintosh-Hemphill Co., Pittsburgh for over 130 years. During the Civil War this company produced cast cannons and also some of the earliest rolls for brass sheets. Certain present day small hard chilled Fe rolls used for special purposes are cast from cupola melted metal. Other cast Fe rolls are cast from Fe melted in air furnaces. Melting procedure and charges for chilled Fe rolls are given. Hardening of rolls is accomplished by a torch and spray method. Corrugated and smooth rolls are made. Following compositions are used for the rolls: Smooth—1.00% C, 1.50% Ni, 0.35% Mo, 1.00% Cr, 0.75% Mn. Corrugated—0.45 % C, 0.35% Mo and 1.25% Mn. These rolls may be used where strength and wear requirements are strict. Slag ladles are made in various sizes. Describes the process. VSP (15b)

Origins of Our Modern Guns. ROGERS BIRNIE. *Army Ordnance,* Vol. 16, Nov.-Dec. 1935, pages 147-153. A review of the period from 1880 to 1890 when steel was adopted for the manufacture of cannon. Early gun steels were oil quenched and then annealed to obtain metal free from internal stresses. DJM (15b)

Free Service Department

For Readers of METALS & ALLOYS

Wanted:—By a well-known manufacturer of Heat and Acid Resisting Castings Sales Representatives who are acquainted with buyers and operating heads in the Steel, Automobile, Chemical and Oil Industries in the following territories: New York, Boston, Philadelphia, Chicago, Cincinnati, Houston and Birmingham. No objection to one or two more lines. Reply giving references and full information as to qualifications. Address Box MA-2, Care of Metals & Alloys, 330 W. 42nd St., New York, N. Y.

REPRESENTATIVE WANTED—A manufacturer of heat resisting alloys and castings seeks representation in both the Philadelphia and New England territories. We are looking for a manufacturer's representative now calling on metal working plants who has the entree to the heat treating supplies market. Write Box No. MA-3, METALS & ALLOYS, 330 42nd Street, New York, N. Y.

Junior Executive Available—M. I. T. Graduate. General engineering experience, Chase Brass and Copper Company. Purchasing chemicals and equipment, R. H. Macy and Company. Single, Christian, references. Box No. MA-4, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

POSITION WANTED: INSPECTOR, SUPERVISOR or INSTRUCTOR of WELDING. Specialized 8 years in arc welding. Knowledge of Metallography, Heat-Treating and Physical Metallurgy. Capable of performing tests and conducting investigations of Weld-Metal. Sales experience. Member of American Welding Socy. and American Socy. for Metals. Good Linguist. Consider position outside U. S. Available July First. Address box MA-6, care of METALS & ALLOYS, 330 W. 42nd Street, New York, N. Y.

FURNACE DESIGNER—Wanted by a manufacturer of electric furnaces. Man with experience designing and estimating electric heat treating furnaces; batch, continuous and salt bath. Give full details of experience, references and salary desired in first letter. Position will be permanent to right man. Address Box No. MA-7, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

CURRENT NEWS ITEMS

The Chemistry of Metals

A symposium on "The Chemistry of Metals" was the feature of the April meeting at the Chemists' Club in New York of the New York Section of the American Chemical Society. There were three speakers: Dr. John Johnston, director of the United States Steel Corp., Research Laboratory, Kearny, N. J., who spoke on "The Chemistry of the Ferrous Metals"; C. E. MacQuigg, metallurgist, Union Carbide & Carbon Research Laboratories, New York, whose subject was "The Chemistry of the Ferrous Alloys" and Prof. C. H. Mathewson, head of the metallurgical department of Yale University, New Haven, Conn., who discussed "The Chemistry of the Non-Ferrous Metals and Alloys." There was a large attendance.

Dr. Johnson emphasized the fact that researches on the chemistry of the blast furnace have shown that the efficiency of coke in the chemical reactions is about 80 per cent, a figure hardly likely to be improved upon. So far as low temperature reduction of ores is concerned, he said that the economical production of sponge iron in competition with scrap is not yet feasible. Discussing steel melting processes, he believes that it is possible to produce in the Bessemer converter as good steel as in the open-hearth, if it is efficiently and scientifically operated.

Bethlehem's New Motion Picture on Alloy Steel

The Bethlehem Steel Co. has announced the completion of a new talking motion picture entitled, "The Making of Alloy Steel." All of the various processes, beginning with the charging of the open-hearth furnace through to the loading of finished bars on freight cars, are shown in this picture. The picture very clearly depicts the care that must be taken at every stage in the making of alloy steel and also the checking and re-checking that is necessary throughout its development in order to assure that the steel will be made according to specifications.

The charging and tapping of the open-hearth, the making of various alloy and other additions to the metal, preparation of the molds, pouring of ingots, placing of hot-tops and other details are shown. From the soaking pits on through the blooming mill and the bar mills, the progress of the steel from ingot to bar is faithfully followed. Operations in the modern electric heat treating department at Bethlehem are shown, as well as many tests made during the progress of manufacture.

The picture shows all of these various operations, just as they occur in the ordinary routine of making alloy steel. The explanatory lecture on the sound track follows the various processes of manufacture and explains the results obtained in the case of many of the operations and treatments. It is a technical picture throughout and is intended primarily for technical audiences. It is a 16mm picture and takes 45 mins. to show.

Balanced Alloys Stressed at Moscow

The importance of balanced alloys in chromium and manganese steels was stressed by Dr. A. B. Kizel of Union Carbide and Carbon Research Laboratories, Inc., in a lecture recently delivered in Moscow, Russia, before the society for Science and Culture. Balanced alloy steels were defined as those that contain alloying elements and carbon so proportioned that the optimum combination of desired properties is obtained.

The first part of the address centered on low-alloy structural steels that are immediately usable in the as-rolled condition. The remainder of the talk was devoted largely to balanced high chromium-manganese stainless steels.

Earl C. Smith, chief metallurgist of **Republic Steel Corp.,** has announced the appointment of Muir L. Frey to the metallurgical staff with headquarters at the Republic plant in Buffalo. Mr. Frey comes to Republic from John Deere Tractor Co. in Waterloo, Iowa, where he has held the position of chief metallurgist for the past ten years.

Mellon Institute's Metallurgical Work

The report of the director, E. R. Weidlein, to the trustees of Mellon Institute, for the work of March 1, 1935, to March 1, 1936, while dealing chiefly with topics in industrial, organic and medical chemistry, contains a few items of metallurgical interest. Asbestos-protected metal, with the asbestos bonded onto galvanized steel by contact when the zinc coating is molten or plastic, is mentioned Some undescribed advances relating to drawing and processing of steel wire, and the development of a new alloy steel for razor blades, also undescribed, are also mentioned.

Some work is in progress relating to silicosis. Other projects of metallurgical interest relate to refractories. Cast, electrically fused refractories are under development. It has been found in work on other refractories that the emissivity of light-colored refractories decreases rapidly with increase in temperature above 400 deg. F., which is said to be of interest to electric furnace operators.

Ceramic Society's New Officers

At the annual meeting of the American Ceramic Society, held in Columbus recently, the following officers for 1936-1937 were elected: President, Francis C. Flint, chief chemist, Hazel-Atlas Glass Co., Zanesville, Ohio; vice-president, Robert B. Sosman, director of research, United States Steel Corp., Kearny, N. J.; treasurer, H. B. Henderson, H. B. Henderson Co., New Brighton, Pa.; past-presidents, J. M. McKinley, North American Refractories Co., Cleveland and W. Keith McAfee, Universal Sanitary Mfg. Co., New Castle, Pa.

New Name and Sales Plan for Askania

The business in automatic regulation, previously carried on by H. A. Brassert & Co. in the iron and steel industry and by the American Askania Corp. in other industries, has been united and placed in the hands of a newly organized company which is now known as the Askania Regulator Co. This change became effective the first week in March.

With the organization of the new Askania Regulator Co., all sales and manufacturing to all industries will be concentrated within the new organization. This change allows for sales simplification and better service to industry as a whole. The officers and the manufacturing plant of the new company remain the same as that of the old American Askania Corp., 1603 South Michigan Avenue, Chicago, Ill.

The new Askania company will continue to develop and manufacture automatic controls for iron and steel mills, power plants, chemical industries, paper mills, engine and turbine manufacturers, glass works and kindred process industries. Askania control regulates pressure, rate of flow, humidity, speed of rotation, draft, water level, air for combustion and any other condition that is measureable.

John M. Lessells Goes to M.I.T.

The appointment of John M. Lessells, consulting mechanical engineer, of Swarthmore, Pa., as associate professor of mechanical engineering at the Massachusetts Institute of Technology, has been announced. He will be occupied with teaching and research in the field of engineering materials.

The annual meeting of the **Electric Metal Makers Guild** will be held at the Hotel Onesto, Canton, Ohio, June 5 and 6, 1936. Technical Sessions are being arranged, and there is expected a full attendance of the membership.

Dr. Haig Solakian, chief metallurgist of the Geometric Tool Co., has accepted a position as research metallurgist with the **A. F. Holden Co.,** metallurgical engineers, New Haven, Conn. Dr. Solakian received his D.Sc. degree from the Massachusetts Institute of Technology.

F. Hall Hately, formerly development engineer for Whitehead Metal Products Co., New York, is now in the products development engineering department of Scovill Mfg. Co., Waterbury, Conn.

MANUFACTURERS' LITERATURE

Corrosion and Heat Resisting Stainless Steels

This company claims that it is unique in the respect that its materials are manufactured by special processes involving the direct reduction of chrome ore and providing a closer metallurgical control than has been obtainable heretofore. Type analyses of some standard grades are included in the colorful bulletin. Rustless Iron and Steel Corp., Baltimore, Md. (451)

Drop Forgings

This attractive booklet deals with the characteristics, qualities and uses of drop forgings. It contains valuable information for anyone interested in this subject. Drop Forging Association, Cleveland, O. (452)

Thermal Analyzer

A brochure describing laboratory furnace equipment designed to conduct grain size test, creep tests, thermocouple calibration, etc., and also for precision heat treatment, has been published by the Stanley P. Rockwell Co., Chicago, Ill. (453)

Hardening Control

Useful information regarding case hardening steel is contained in a booklet of the A. F. Holden Co., New Haven, Conn. (454)

Recirculating Furnace

A leaflet lists some of the outstanding features of the "Galvo" furnace as simplified control, even temperature, economical operation, greater heat transfer, indirect firing methods, quicker heating up and flexibility. It was designed to meet the needs of the galvanizing, tinplating and allied industries. F. C. Williams, Inc., Detroit, Mich. (455)

The Jetal Process

Simple immersion in an aqueous bath for about 5 minutes colors all grades of common iron or steel a brilliant and uniform jet black. It is claimed it does not alter dimensions of articles and cannot chip, scale, peel or discolor. Alrose Chemical Co., Providence, R. I. (456)

Heat and Corrosion Resistant Alloys Heated by Gas

Bulletin C1-A illustrates a number of complex castings made from Q-Alloys which are recommended for pipe fittings, furnace parts, etc. General Alloys Co., South Boston, Mass. (457)

MoTung High Speed Steel

An illustrated booklet devoted to the above, contains information under these divisions: working and treatment, surface protection, high heat temperatures, drawing temperatures, effect of treatment, etc. An index is included. Universal Steel Co., Bridgeville, Pa. and Cyclops Steel Co., Titusville, Pa. (458)

Hi-Steel

Information concerning chemical composition, physical properties and corrosion resistance of this steel is offered by the Inland Steel Company, Chicago, Ill. (459)

Controlled Grain Anodes

Seymour Nickel Anodes are homogeneous in grain structure, according to this bulletin. The various available shapes are illustrated and some useful data are given. The Seymour Manufacturing Co., Seymour, Conn. (460)

Silico-Manganese Spring Steel

Extreme care is taken in processing this steel to avoid imperfections, in rolling to obtain cold-shearing qualities and in controlling the uniformity of the structure to insure both high inherent fatigue resistance and uniform heat-treating characteristics, according to the manufacturer. Illustrated. Bethlehem Steel Co., Bethlehem, Pa. (461)

Comparative Metal Melting Costs

A few of the subjects discussed in this colorful, illustrated booklet are: considerations governing selection of melting equipment; design and operation of types of melting equipment and melting costs. Campbell-Hausfeld Co., Harrison, O. (462)

Welding Rods

Hard-facing welding rods Nos. 459 and 217 are the subjects of an illustrated brochure. Hard surfacing can be done with these rods, either electrically or by the oxy-acetylene process to the great majority of ferrous welding parts. American Manganese Steel Co., Chicago Heights, Ill. (463)

Sand Testing Equipment

Catalog No. 103 is a handy reference book on sand testing and foundry control equipment and also contains sand data. It is looseleaf and additional sheets are sent upon request. Harry W. Dietert Co., Detroit, Mich. (464)

Forgings

Information on heat treated molybdenum-chromium-nickel steel forgings for heavy machinery is presented in an illustrated booklet of A. Finkl & Sons Co., Hartford, Conn. (465)

Degreasing

An attractive leaflet describes how modern equipment and solvents make degreasing and cleaning both inexpensive and efficient. Detroit Rex Products Co., Detroit, Mich. (466)

Insulating Firebrick

Bulletin R-2-D contains complete information of the five types of B & W insulating firebrick. A table of physical characteristics, curves of thermal conductivity and a list of applications are among the interesting items in this booklet. Babcock & Wilcox Co., New York, N. Y. (467)

Ramming Mix

An illustrated folder contains the statement that P. B. Sillimanite ramming mix can be used under the most severe operating conditions without deterioration. Recommended uses and instructions for installation are included among the data. Chas. Taylor Sons Co., Cincinnati, O. (468)

Thermometers

Catalog No. 1250 contains information covering liquid-filled, vapor-tension, and gas-filled recording, indicating and controlling thermometers. It also describes a new small-bulb gas-filled thermometer. It is in the form of an engineering reference book and contains about 500 temperature recording charts illustrated in full size. Bristol Co., Waterbury, Conn. (469)

Rust-Proofing

Bulletin No. 7-7 covers all phases of the Cromodine process for rust-proofing steel products. Illustrations of the results of both accelerated and actual service tests prove the value of Cromodizing. American Chemical Paint Co., Ambler Pa. (470)

Yoloy

A colorful bulletin summarizes the properties of the above alloy steel and lists the physical properties of two typical steels in the Yoloy series. It is claimed to be corrosion resistant and to have high tensile strength and high ductility. Youngstown Sheet and Tube Co., Youngstown, O. (471)

Zinc Alloy Die Castings

A technical booklet tells the story of the development of the "Zamak" alloys. Tables and illustrations. New Jersey Zinc Co., New York, N. Y. (472)

Optical Pyrometer

The Burrell optical pyrometer, a direct reading instrument originally designed for use with the Barrett fusion furnace and equally useful for other work requiring an optical pyrometer with a temperature range from 1500 to 3000 deg. F., is described and illustrated in a leaflet published by the Burrell Technical Supply Co., Pittsburgh, Pa. (473)

Molybdenum in Iron and Steel

An attractive brochure contains a summary of the part played by molybdenum in ferrous progress, and claims that a great saving in cost with no impairment in quality can be obtained by its use. The Climax Molybdenum Co., New York, N. Y. (474)

Cutting Oils

A leaflet is devoted to the EFHCut series of oils. It is claimed that this series represents the best straight cutting oils obtainable, at a price which meets and beats competition. E. F. Houghton & Co., Philadelphia, Pa. (475)

Heat Exchanger

Bulletin No. 173 describes the Duriron heat exchanger which is available in the company's corrosion-resisting alloys—Duriron, Durichlor, Durimet, Durco alloy steels and Alcumite. Illustrated. Duriron Co., Dayton, O. (476)

Coreless Induction Furnace

A colorful leaflet contains an explanation of the principle of operation and advantages to be obtained from the use of the Ajax-Northrup electric furnaces. Ajax Electrothermic Corp., Trenton, N. J. (477)

Standard Gas Fired Air Heaters

Publication SC-70 is devoted to these heaters which, it is claimed, are applicable to all low temperature heating operations which may be accomplished by the circulation of heated air and where contact of the material being heated with diluted products of combustion is not objectionable. Surface Combustion Corp., Toledo, O. (478)

Phosphor Bronze

A leaflet lists the sizes in which the company's twelve-inch stock bushing bars are now offered. The Phosphor-Bronze Smelting Co., Philadelphia, Pa. (479)

Centrifugal Castings

Advantages, analyses of metal—sizes of tubes, application, machining and welding and production facilities of these castings are discussed in an illustrated folder of The Duraloy Co., Pittsburgh, Pa. (480)

MANUFACTURERS' LITERATURE

Thermal and Sound Insulation

A catalog devoted to the above contains the statement that the Rockwool products discussed have been developed to the highest degree of efficiency to cope with temperatures from 400 deg. below zero to 2000 deg. F. and for every industrial and domestic requirement. Many of the different applications are illustrated and described. General Insulating and Manufacturing Co., Alexandria, Ind. (481)

Oxwelding Brass and Bronze

This booklet is divided into two main sections, the first devoted to the technique of fusion welding brass and bronze, the second is an illustrated section on the welding of commercial yellow brass pipe. Joint design and welding technique are discussed in detail. Linde Air Products Co., New York, N. Y. (482)

Resistance Wire

Catalog K deals with Hoskins Chromel and other electrical resistance wires. Tables, diagrams, technical data, comparison of wire gauges and much other useful information. Hoskins Mfg. Co., Detroit, Mich. (483)

Soldering Flux

The Eureka Soldering Flux Crystal, a dry, granulated product specially desirable for soldering on copper, brass, tin plate, sheet iron and galvanized ware is the subject of a colorful folder. Grasselli Chemical Co., Inc., Cleveland, O. (484)

Electric Ammonia Dissociators

May be used to replace hydrogen in practically all industrial applications, effecting a decided reduction in gas cost. Ajax Electric Co., Inc., Philadelphia, Pa. (485)

Torsion Impact Testing Machine

Bulletin No. 114 discusses the Carpenter machine whose operation is very simple and requires only one operator. Baldwin-Southwark Corp., Philadelphia, Pa. (486)

Weatherproof Line Wire

Publication GEA-2103 gives information on a new wire with varnished cambric and a weatherproof braid treated with U.R.C. compound, General Electric Co., Schenectady, N. Y. (487)

Grinding for the Railroad Shop

As grinding is the recognized means of obtaining accurate, close-fitting and long-wearing parts at minimum costs it is rapidly coming into more general use by the railroads according to an attractive pamphlet of the Norton Co., Worcester, Mass. (488)

Vanadium Facts

Another issue of this publication contains accounts of progress and performance in the field of alloy steels. Vanadium Corp. of America, New York, N. Y. (489)

Combination Impact Tester

This machine will make either izod, charpy, or tension tests quickly and accurately, and with minimum operator effort according to an illustrated pamphlet which is issued by the Riehle Testing Machine Div. of American Machine and Metals, Inc., East Moline, Ill. (490)

Granite City HS Grades 1 and 2

Information concerning the Granite City manganese high tensile steels can be obtained from the Granite City Steel Co., Granite City, Ill. (491)

X-Ray and the Foundry

Interesting treatise on this subject setting forth how the X-ray has now come to the fore as a tool of the testing laboratory. Kelly-Koett Mfg. Co., Inc., Covington, Ky. (492)

Brazing Alloy

Bulletin No. 5 advocates the use of "Sil-Fos" for joining brass, bronze, nickel, nickel silver, extruding brass and bronze, Monel metal and other non-ferrous metals and alloy fusing above 1300 deg. F. Handy & Harman, New York, N. Y. (493)

Properties of OFHC Copper

An attractive booklet contains reprints of three papers relating to the above subject. Photographs, diagrams and photomicrographs are used to illustrate them. United States Metals Refining Co., New York, N. Y. (494)

Mallory Elkon

Looseleaf catalog containing engineering data with descriptions, illustrations and recommendations for the selection of electrical contacts for all types of service. P. R. Mallory & Co., Inc., Indianapolis, Ind. (495)

Phosphor Bronze

This attractive brochure illustrates ten of this company's mill processes, with descriptive captions, in the making of phosphor bronze. Some typical fabricated products are also shown. Miller Co., Meriden, Conn. (496)

Grinding Lubrication

Many facts about grinding solutions are given in this booklet. An outline for the selection of grinding wheels is one of the factors contributing to its usefulness. D. A. Stuart & Co., Chicago, Ill. (497)

Forgings

The story of this company's forgings is told in a well-illustrated booklet. Reference tables give helpful data. Heppenstall Company, Pittsburgh, Pa. (498)

Metal Stampings

A small lot stamping service without prohibitive die costs is the subject of an illustrated leaflet of the Dayton Rogers Mfg. Co., Minneapolis, Minn. (499)

Indium

The development, characteristics and chemical properties of this rare metal are featured in an illustrated leaflet. Grasselli Chemical Co., Inc., Cleveland, O. (500)

Atmos-Gas Producer

Bulletin No. 101.4 is devoted to the above, which produces a treated gas suitable for the bright annealing of steel without decarburization according to the manufacturers, with modifications suitable for bright annealing copper and brass. Illustrations. C. M. Kemp Mfg. Co., Baltimore, Md. (501)

Bearing Security

This leaflet lists the four essentials of a bearing metal and claims that Ajax Bull Bearing alloy embodies them. Ajax Metal Co., Philadelphia, Pa. (502)

Spencer Turbo-Compressors

This bulletin which has illustrations of the complete range of sizes of this equipment also contains: "Midget" Turbo for individual mounting, a single-stage line which effects new economies and Gas-Tight Turbos for acid and explosive gases. Spencer-Turbine Company, Hartford, Conn. (503)

Konik

Data on this steel's physical properties, corrosion resistance and working, are offered by the Continental Steel Corp., Kokomo, Ind. (504)

Potentiometer Controllers

Bulletin No. 202 covers the complete line of potentiometer and resistance thermometer controllers. A number of simplified wiring diagrams showing how an installation looks are included. Foxboro Company, Foxboro, Mass. (505)

Research Puts the Diatom to Work

This booklet discusses the history of the diatom from which Celite is made. The four main industrial services of Celite: high temperature insulation, a filter aid, mineral filler and workability agent in concrete are described. Illustrations. Johns-Manville, New York, N. Y. (506)

Sicromo Steel

High temperature data sheets containing full information on this steel have been issued by The Timken Steel & Tube Co., Canton, O. (507)

A. W. 70-90

This bulletin describes the new high-strength "70-90" steel in sheets and plates. An article on the engineering aspect of high-strength sheet steels is included. Alan Wood Steel Co., Conshohocken, Pa. (508)

Dowmetal Data Book

A new edition of this book, containing especially significant accomplishments since the last data book, in the sections Available Forms and Shop Practice has been published by The Dow Chemical Co., Midland, Mich. (509)

Fire Clay Products

The various Goose Lake products and Therm-O-Flake, for high temperature insulation are briefly described in a leaflet from the Illinois Clay Products Co., Joliet, Ill. (510)

Seamless Flexible Tubing

Bulletin 1936-1 contains the statement that American tubing is the most reliable type of flexible metal conveyor obtainable for services where absolute, 100 per cent tightness is essential. American Brass Company, Waterbury, Conn. (511)

Convected Air Tempering Furnaces Heated by Gas

Bulletin No. 40 concerns these furnaces which use the principle of mechanical convection to the maximum by incorporating in the design a patented rotary fan to drive the heated air downward with pressure and great velocity, in and around through the parts to be processed. Despatch Oven Company, Minneapolis, Minn. (512)

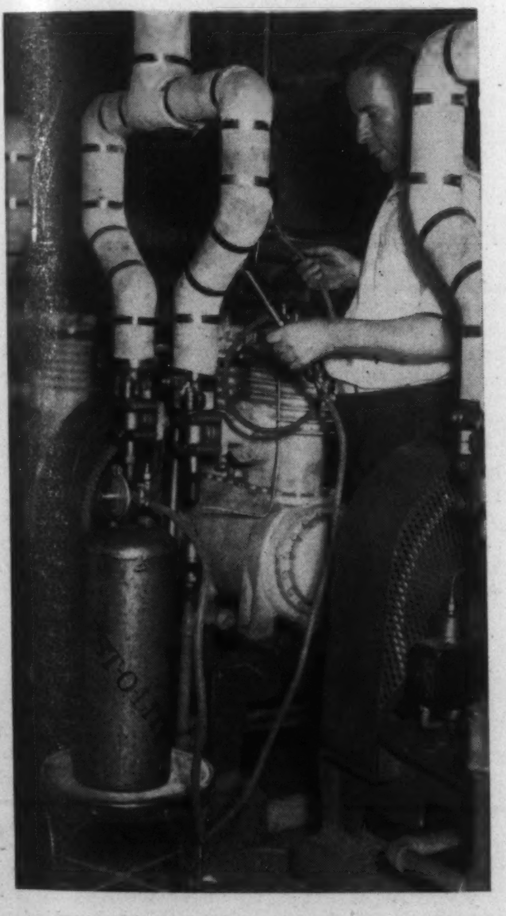
NEW EQUIPMENT AND MATERIALS

Halide Leak Detector for Refrigerant Gases

During recent years there has been a continued growth in the use of non-combustible halide gases as refrigerants. The fact that these gases are relatively odorless, tasteless, and colorless renders it necessary to have a quick and sure method of locating leaks while cooling units are being installed and later during servicing. Such a device, known as the "Prest-O-Lite Halide Leak Detector," has been developed by The Linde Air Products Co., 30 East 42nd St., New York.

The Halide Leak Detector consists of a regular Prest-O-Lite needle valve torch handle assembly, a burner which includes a suction nipple for attaching a rubber hose, and a chimney with a copper reaction plate. The rapid flow of acetylene through the burner causes a suction which draws in any refrigerant gas near the open end of the suction tube.

To operate the detector, the flame is first adjusted so that the top of the outside cone is level with or slightly above the chimney of the detector. The open end of the suction tube is used to explore around those places where a leak might occur. Any halide refrigerant gas drawn into the burner is decomposed with the formation of free acids. These acids, coming into contact with the hot copper reaction plate cause instant color response in the flame. Visible color indication of the smallest concentration of refrigerant gas by a green-tinted flame is given by the Prest-O-Lite Halide Leak Detector. When a large amount is present, the flame assumes an intense violet color. After the source of the leak has been passed, the flame clears almost instantly.



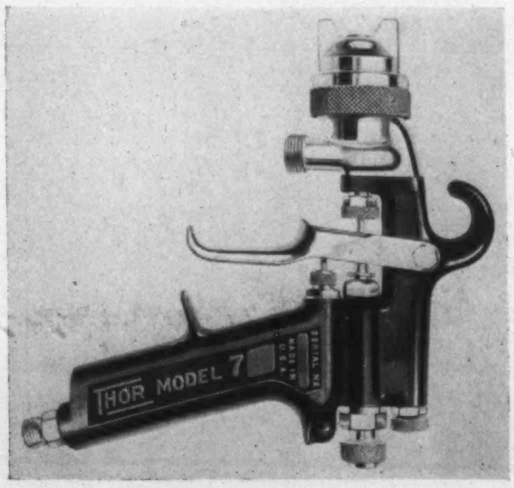
The Prest-O-Lite Halide Leak Detector affords a simple method of locating halide gas leaks, even in difficultly accessible places.

The two-color variation of flame gives visible indication of the amount of refrigerant gas present. If there is a considerable amount of refrigerant gas in the surrounding atmosphere, the leak can be located by the variation in the intensity of the color of the flame.

The Prest-O-Lite Halide Leak Detector is a simple, positive, supersensitive device which saves time in locating leaks, avoids waste of refrigerant gas and costly equipment shutdowns, and provides a sure method for determining the presence of these gases in the atmosphere.

A Fast Production Spray Gun

Greater speed, less air consumption, perfect atomization—these are some of the improvements which are causing Binks new "Thor Model 7 Spray Gun" to be hailed as one of the greatest engineering triumphs in spray painting history, says the Binks Mfg. Co., 3114 Carroll Ave., Chicago. The Thor Model 7 has been skillfully engineered after giving practical consideration to all phases and problems of the spray gun users of this country. It includes the suggestions of engineers of some of the country's largest industries, where smart finishing must be obtained at the lowest possible cost. A departure from all the other spray guns is the introduction of color into the gun body which is durable drop forged aluminum with a black electrolytic coating for surface protection.



A Filler for Cash Iron

A new product has recently been placed on the market for the porcelain enamel industry called "E-6 Cast Iron Filler." This filler is manufactured by the Porcelain Enamel & Mfg. Co., Baltimore, and it receives that same strict supervision that the "Pemco" staff of technicians has always adhered to in the manufacture of its frits and oxides.

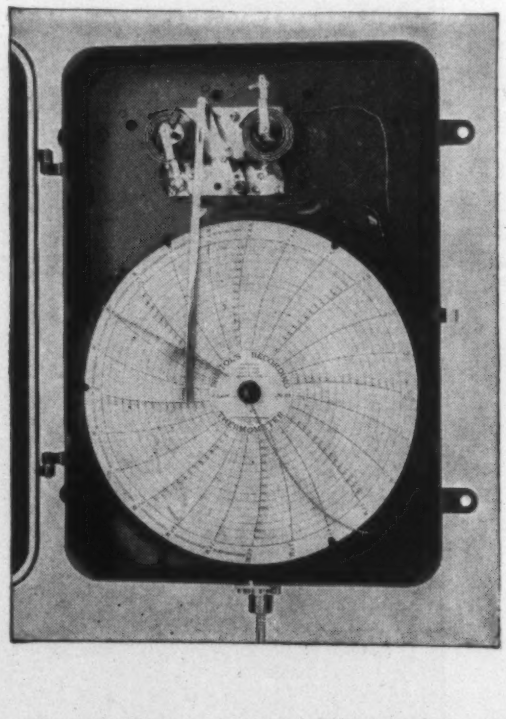
The scientific treatment that E-6 Cast Iron Filler receives makes it the most formative filler on the market today. If used carefully, it will prove to be very hard, almost making itself part of the iron, thereby, assuring the user that this filler will, no doubt, save him many bad castings. While not only saving many dollars by reducing his scrap pile, this filler will help the manufacturer to keep his production at a steady rate, instead of being held up by bad castings, says the company.

A Small-Bulb Gas-Filled Thermometer

An accurate gas-filled recording thermometer, having a small temperature-sensitive bulb for long lengths of connecting tubing, has for many years been the dream of every instrument engineer. Such a thermometer, Bristol's "Small-Bulb Gas-Filled Thermometer," has at last been successfully developed. It is offered for measuring temperatures between —60 deg. F. and 1000 deg. F., where tubing lengths as long as 100 ft. and even longer under certain conditions, are required by the application.

This instrument has all the features that have made Bristol's gas-filled thermometers the choice of engineers in every industry for over 40 years. It is extremely accurate under all conditions of temperature both along the tubing and in the case; it responds quickly to rapidly fluctuating temperatures at the bulb; and it records on a uniformly graduated chart.

The Small-Bulb Gas-Filled Thermometer consists of a rectangular case in which there are mounted two Class 111 measuring elements, connected through a compensating mechanism. Two capillary tubes, filled with the same gas, run from each element through one armor tube to the sensitive portion of the bulb. Only one capillary tube is connected to the temperature-sensitive bulb. The other is closed at the bulb end. Both capillary tubes, being adjacent, are subjected to the same temperature changes. Through the compensating mechanism, the tube and element not connected to the bulb correct for temperature changes along the connecting tube and in the case. In other words the tube and element not connected to the bulb produce a balancing action which exactly offsets the effect of temperature variations along the tube and around the measuring element connected to the bulb.



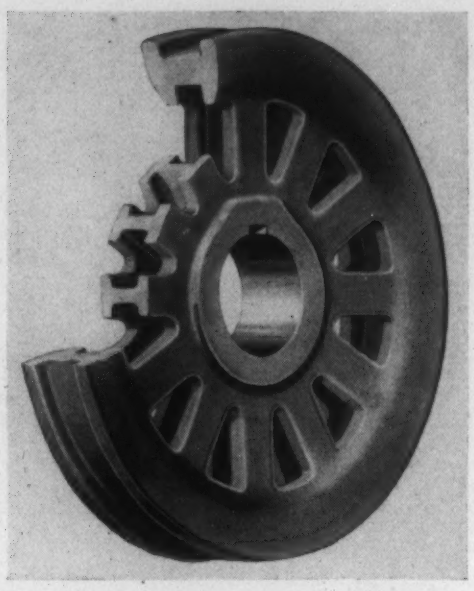
Lengths of tubing up to 100 feet and even longer under certain conditions can be furnished with small size bulbs.

Small-Bulb Class 111 Thermometers are offered with one or two pens in the 12-inch chart size; and with one pen only in the 8-inch chart size.

"Double-Wall" Crane Wheels

Rapid depreciation of ordinary traveling crane track wheels was the reason, many years ago, for the wide adoption of cast, heat-treated, austenitic manganese steel wheels for the heaviest and most abusive service. They have been employed with general satisfaction by steel mills, heavy machinery builders, railroad locomotive shops and the like, for at least 25 yr. Even when made in the single web conventional type, manganese steel crane wheels have shown superior economy and much longer than ordinary service life. The tough, ductile, work-hardening metal insures largely against rapid wear, surface cracking, and flat spots on the treads; and breaking of the flanges, or the web at flange or hub, has always been rare.

To obtain full advantage of these well-known characteristics of 13 per cent manganese steel, and to eliminate entirely the possible breakage of the web, "Amsco" engineers have designed the double wall crane wheel illustrated. The walls are continuous with the flanges, giving them a strong but elastic support and high resistance to side thrusts. The walls are integrally tied together with internal cross-spokes. Metal sections are equalized, making possible, in manganese steel foundry practice, a perfect heat treatment, resulting in the maximum toughness in the steel.

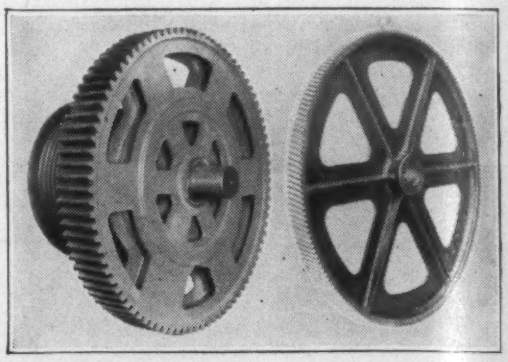


The inherent structural strength of the new double wall design, combined with the acknowledged toughness, strength and wear-resistance of manganese steel, makes these wheels highly economical in all traveling crane service, and particularly under the heaviest, most abusive and most abrasive conditions. "Amsco Double Wall" manganese steel crane wheels are made in all diameters, for all cranes, with hub lengths, bores and other optional dimensions to suit the user's requirements. A dimension and data sheet is available to those interested in this new product from the American Manganese Steel Co., Chicago Heights, Ill.

Welding for Crane Gears

The Harnischfeger Corp. of Milwaukee, a leading builder of electric overhead traveling cranes, has recently developed a new means of fabricating gears through the use of welding with rolled steel. Lighter weight with greater resistance to wear and strain is claimed.

Illustrated herewith are two types of gears with helical and spur cut teeth showing how these gears are built up with arms or webs of rolled steel, reinforced with gear bands welded integrally. The entire unit is normalized to provide the greatest possible strength.



Through this type of construction, all danger of casting flaws is eliminated. In addition, there is the advantage of being able to select special steels for members which are subject to high stresses. Easier replacements able on request.

A Light Hoist Called "Zip-Lift"

An entirely new line of electric hoists, known as the "Zip-Lifts" with capacity ratings from 250 to 500 lbs., is announced by the Harnischfeger Corp. of Milwaukee.

Designed primarily for "spot handling" work in machine shop, welderies, storage booths, foundries, etc., these units are of all welded construction and are exceptionally light, the quarter-ton model weighing only 100 lbs. With a ball bearing motor especially designed for hoisting service and smooth operation through a simplified planetary gear train which is fully enclosed and running in oil, the "Zip-Lifts" have hoisting speeds up to 32 ft. per min. and are controlled either by push button or pendant rope. To simplify installations, all complicated wiring has been eliminated so that for hook, trolley or jib crane service they need only be hooked up and plugged in like the average electric appliance.

Positive safety is assured with weight-type limit switch, solenoid dry disc motor brake and ratchet and roller type mechanical brake. Standard units are furnished with or without trolley.

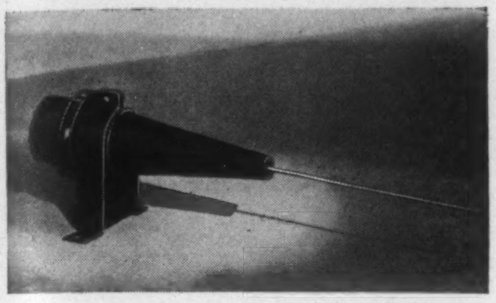
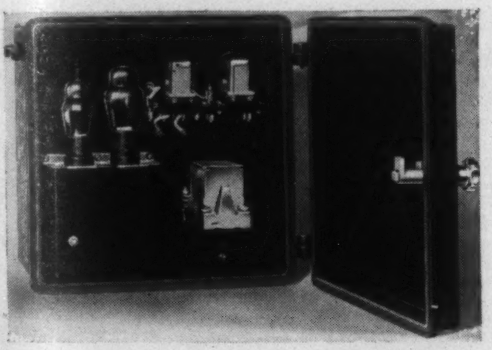
Protectoglo System of Combustion Safeguard

A new and materially improved line of "Protectoglo" equipment has just been placed on the market by The Brown Instrument Co., a division of Minneapolis-Honeywell Regulator Co., Philadelphia. This apparatus includes two separate and distinct types of relays, and a flame sensitive electrode which can also be used as a special spark plug for electric ignition. Any of the standard line of primary controllers and motor valves are used to complete the system of combustion safeguard.



The development of this equipment, which marks a very definite step forward in the combustion safeguard field, came only after several years of field experience with the old Protectoglo System, manufactured by the Minneapolis-Honeywell Regulator Co., had proved that the utilization of the electrical conductivity of the flame itself provides the greatest possible measure of safety and reliability that engineers have been able to incorporate simply and positively in any combustion safeguard.

The relays contain the thermionic tubes for rectification and amplification of the power input which, when conducted from the electrode unit to ground through the flame, operates the relay units controlling the operation sequence, main fuel valve, etc. Obviously any interruption in the circuit to ground through the flame (flame failure) causes instantaneous and positive shut-down. The cast iron dust and moisture-proof relay cases are of the universal type for either front of board or flush mounting.

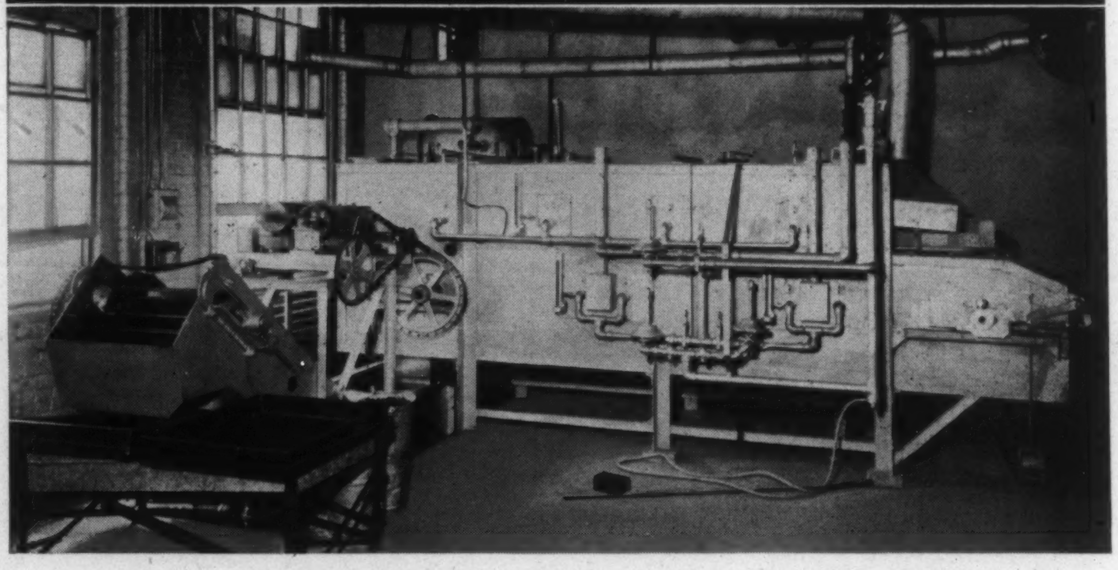


Outstanding features of the Protectoglo System: (1) Standard radio type vacuum tubes are used, assuring long tube life; (2) the vacuum tubes are located in the relay case where they are well protected and under lock and key; (3) the relay can be located in any remote location with reference to the electrode unit; (4) the relays are housed in a rugged cast iron case; (5) a rubber gasket is used on the hinged relay cover, making the case dust and moisture-proof; (6) combination door handle and built-in key lock on relay cases; (7) the terminal board is located in a separate moisture-proof chamber in the relay case; (8) electrode unit contains no moving parts and is of a very rugged design.

A system of combustion safeguard can be supplied for practically any type of burner equipment.

Heating time
REDUCED...

....when furnaces are built with Armstrong's **EF** *Brick*



USE of Armstrong's EF Insulating Fire Brick insures accurate temperature control—and more! Because it requires no fire brick protection, this lightweight semi-refractory brick can be laid up in thinner walls. The result is less time needed to bring the equipment to temperature, with a consequent saving of fuel and speeding up of production.

This brick is available for two temperature ranges—EF-22 for temperatures as high as 2200° F.; EF-26 for temperatures as high as 2600° F. Armstrong's EF Insulating Fire Brick can be used for any type of furnace—gas, oil, coal, or electric-operated.

SHOWN ABOVE—*Gas-fired, muffle-type hardening furnace for heating and hardening cap and set screws and other small parts—built by W. S. Rockwell Co. with Armstrong's EF-22 Insulating Fire Brick.*

~ ~ ~

We'll be glad to supply you with samples and data on EF Insulating Fire Brick—also the other high temperature insulation products in the complete Armstrong Line. Write Armstrong Cork Products Co., Building Materials Division, 982 Concord Street, Lancaster, Pennsylvania.

JOHN ATTWOOD, SECTION EDITOR

Trend of Ore Treatment and Its Bearing on Lake Superior Iron Ore Reserves. CARL ZAPFFE. *Mining Congress Journal,* Vol. 22, Jan. 1936, pages 17-23, 52. Ore treatment was inaugurated on a large scale only 25 years ago and consisted then of one very large plant designed to treat large quantities of ore material which contained loose sandy particles that were removed by washing. By this method ⅓ of the crude ore tonnage was wasted; nevertheless it was economically practical, and it appeared to be the only applicable method of treatment likely of adoption. The equipment used in the earlier washing plants has now become simplified and the recoveries have increased greatly. The tonnage treated by washing has also been increased. Washing plants are now distributed nearly the full length of the Mesabi Range. Jigging which had been deemed impractical has now become adopted, both as a separate installation and as an adjunct where washing is used. Typical Fe ores are being converted into shipping material by roasting followed by magnetic separation. Magnetic separation of portions of Fe-bearing formations carrying magnetite has been shown feasible on a large scale. Drying wet ores and sintering fine ores is being practiced regularly in 2 or 3 districts. Flotation has also been introduced. Leaching has been found feasible in the treatment of iron ore formations of high Mn content. Mixing and grading are being carried out to a state of perfection which constitutes the ultimate purpose. BHS (1)

Gold Minerals in Brazil (Consideracoes a Mineracao do Ouro no Brasil) R. KNAUER. *Chimica e Industria,* Vol. 3, Oct. 1935, pages 92-93. Mineralogical and geological conditions, methods of ore dressing and possibilities of this Brazilian industry are briefly reviewed. Ha (1)

Variety of Improvements Noted in Concentration and Milling. CHARLES E. LOCKE. *Mining & Metallurgy,* Vol. 17, Jan. 1936, pages 13-15. Some of the improvements noted during the past year are a new model Fahrenwald crusher to be on the market soon. Symons' fine reduction cone crusher and Taylor secondary crusher continue to gain as intermediate crushers. Hadsell mill has been further improved. Latest design of ball mills of American Ball Mill Co. have boltless liners and are mounted on SKF antifriction bearings. In vibrating screens the Symons flat balanced, the Telsmith circular vibratory and Robins Conveying Belt Co's. circular throw balance screen are new. Hardinge counter current classifier is efficient. Radical change has been made in Dorr equipment. New facts have been brought out by U. S. Bureau of Mines on magnetic properties of minerals, enlarging the field of magnetic separation and leading to design of new apparatus. New aerofloat reagents of American Cyanamid Co. are Na aerofloat "B" and reagents 203, 243 and 208. No. 244 has replaced ethyl xanthate. What seems a revolutionary process for Au and Ag involves: (1) Rapid dissolution of metals in finely ground pulp by cyanide; (2) Precipitation by charcoal; and (3) Flotation of metals. VSP (1)

Recent Trends in Design and Construction of Copper Concentrators in the Southwest. C. E. RORK. *United States Bureau of Mines, Information Circular* No. 6866, Nov. 1935, 15 pages. AHE (1)

Tabular Index of Bureau of Mines Information Circulars on Mining and Milling Methods. J. R. THOENEN. *United States Bureau of Mines, Information Circular* No. 6858, Nov. 1935, 105 pages. AHE (1)

The Enzlin-Rockey Precious Metal Extraction Process. *South African Mining & Engineering Journal,* Vol. 46, pt. II, Nov. 2, 1935, page 269. Descriptive. AHE (1)

1a. Crushing, Grinding & Plant Handling

Magnetite as a Standard Material for Measuring Grinding Efficiency. R. S. DEAN. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 660, Feb. 1936, 5 pages. Gross & Zimmerley have proved that the energy actually used in grinding is proportional to the new surface produced. Gottschalk found that coercive force of magnetite powder was directly proportional to surface area. To study crushing efficiency it is only necessary to charge the machine with 10-mesh magnetic and measure the power input while grinding. The coercive force of the ground sample is then determined by a simple method. Data are given to show that the method actually works. JLG (1a)

1b. Gravity Concentration

Log Washers in the Aggregate and Flux-stone Industries. A. R. AMOS, JR. & S. B. PATTERSON. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 679, Feb. 1936, 10 pages. Describes several installations and discusses results. JLG (1b)

Some Notes on Classification Trends in America. JOHN VAN NOSTRAND DORR. *Journal Chemical, Metallurgical & Mining Society South Africa,* Vol. 36, Oct. 1935, pages 66-81. The use of the classifier as a sand circulator or ball mill loader is increasing. The flow sheets of the grinding plants of 3 mills are given and discussed. The circulating load in these mills ranges from 4 to 9 times the new feed; another is operating at 10:1 — 15:1. The only limitations to the upward trend of circulating load are mechanical. The sharpness of the separation is not unduly influenced by the amount of circulating load. An increase in the circulating sand load has resulted in increased grinding measured by increased production of material of definite fineness. The overall result is lessened costs. AHE (1b)

1c. Flotation

Flotation at Government Gold Mining Areas. *South African Mining & Engineering Journal,* Vol. 46, pt. II, Nov. 16, 1935, page 339. Fagergren flotation machines following corduroy tables are to be used to separate the pyrite for separate grinding and cyanidation. AHE (1c)

The Flotation of Gold Ore at the Bibiani Mine. W. J. CAYZER. *South African Mining & Engineering Journal,* Vol. 46, pt. II, Nov. 2, 1935, pages 281-283. The old plant, a battery of 50 stamps followed by amalgamation and cyanidation, gave sand tailings assaying 1.5 dwts./ton and slimes containing 4.2 dwts. due to Au in pyrite. A new plant consisting of a 5 x 10 ft. ball mill, Simplex classifier, Dorr agitators and thickeners gave a 3.60 dwt. tailing from a 12.0 dwt. ore. Later ball mill discharge was fed to corduroy tables, which recovered more than ⅓ the Au. The concentrate was roasted and charged back into the ball mill circuit. Extraction was more than 81% at 40% —200 mesh. Finer grinding was uneconomic, even at 92% extraction. A new flow sheet using flotation was adopted. Use of soda ash was not beneficial. $CuSO_4$ did not activate the pyrite. Cresylic acid gave no increase in extraction. Starch to depress graphite decreased extraction. Au recovery by flotation was 93% and that by cyanidation 97%. AHE (1c)

Flotation of Ores (La flotation des minerais) L. BENETT. *Génie Civil,* Vol. 107, Sept. 14, 1935, pages 248-250; Sept. 28, 1935, pages 293-296. Comprehensive summary of the present conceptions underlying flotation phenomena. Depressing agent determines the solid which will be eliminated. As depressing agents can be used: protective colloids, salts giving colloidal hydroxides when acted upon by water, metals forming with the solid a more insoluble salt than the gatherer, ions, such as cyanides, forming a polar film, changing in pH by lime addition or otherwise, and salts destroying films on previously activated solids. JDG (1c)

Concentration of Stanniferous Ores by Rheolaveurs at Manono, Belgian Congo (La concentration des minerais stannifères par rhéolaveurs, à Manono, Congo Belge) CH. BERTHÉLOT. *Génie Civil,* Vol. 107, July 27, 1935, pages 90-91. In this installation 60 m.^{3} of ore are treated daily. The ore carries 500-1100 g./m.^{3} of cassiterite and contains about 50% of clay. Cassiterite sand recovered is quite small sized, more than 70% of it is smaller than 1 mm. Recovery reaches 90-95%. A sketch of the installation and operating practice is given. JDG (1c)

Flotation of Galena and Chalcocite of Near-Colloidal Size with Potassium Amyl Xanthate and Amyl Dixanthogen. PLATO MALOZEMOFF. *Journal of Physical Chemistry,* Vol. 39, Nov. 1935, pages 1043-1056. The action of potassium amyl xanthate and of amyl dixanthogen on galena and on chalcocite of near-colloidal size appears to be identical when the mineral is ground in air. Concentration of hydroxyl ion greatly influences the flotation of sulphides. High pH is conducive to better flotation of chalcocite of near-colloidal size with amyl dixanthogen and with potassium amyl xanthate, whereas it is destructive to flotation of galena with the same reagents. It is proposed that the hydroxyl radical influences the formation of reaction products whose formation in turn affects flotation of the sulphide mineral. Under the experimental conditions employed, oxygen in grinding has a noticeable injurious effect on the flotation of chalcocite and of galena with potassium amyl xanthate and with amyl dixanthogen, as evidenced by the results obtained when the minerals are ground in virtual absence of oxygen; they are superior to any hitherto obtained in this research. The action of potassium amyl xanthate and of amyl dixanthogen on galena and on chalcocite appears to be identical when the mineral is ground in a "neutral" atmosphere, i.e. in virtual absence of air. EF (1c)

1d. Magnetic Separation

Separation of Hematite by Hysteretic Repulsion. E. W. SCHILLING & HARWICK JOHNSON. *Metals Technology, American Institute Mining & Metallurgical Engineers Technical Publication* No. 654, Dec. 1935, 13 pages. Although hematite is normally considered nonmagnetic and does not respond to the usual methods of magnetic separation it has been found that specular hematite is very active in an alternating magnetic field. If this is a polyphase field the material can be made to move longitudinally as well as laterally. Red hematite may be made magnetically active by a proper heat treatment. Such activated particles were often repelled with such force that they jumped 2" or 3" in the air. Curves show the amount of hematite moved in unit time as a function of field strength, air gap, frequency of excitation, magnitude of vibration, frequency of vibration, and heat treatment. JLG (1d)

Magnetic Separators (Nagot om magnetiska malmseparatorer) GUST G. BRING. *Jernkontorets Annaler,* Vol. 119, Oct. 1935, pages 412-452. The general conclusions of the tests are: (a) Cubes of pure magnetite ore are attracted with a force proportional to their volumes and weights; (b) the conventional formulas for calculating the attraction give values higher than are observed in practice; (c) centrifugal force plays no significant role; (d) the attractive force is approximately proportional to the field strength; (e) the attractive force falls off as the magnetite concentration is decreased; (f) the attractive force falls off very rapidly with distance; (g) iron drums are more effective than drums of non-magnetic material, but the drums must not be too thick; (h) non-magnetic ores which were heated with small amounts of reducing material produced magnetic oxides which possessed greater magnetic strength than corresponded to its content of magnetite. HCD (1d)

The Magnetic Separation of Minerals. *Mechanical World & Engineering Record,* Vol. 98, Nov. 22, 1935, pages 506-509, 512. Two magnetic separators with (a) a shaking conveyor belt and (b) with a fixed conveyor belt are described. WH (1d)

2. ORE REDUCTION

A. H. EMERY, SECTION EDITOR

2a. Non-Ferrous

The Zinc Industry. STANLEY A. EASTON. *Mining Congress Journal,* Vol. 22, Feb. 1936, pages 14-15. A review of the experimental work that led up to the building of the electrolytic Zn plant of Bunker Hill & Sullivan at Wallace, Idaho. This plant uses high acid electrolyte and high current density, producing a Zn of very high purity. BHS (2a)

Production of Copper Aluminum Alloys by Electrolysis of Aluminum Dross. A. I. ZHELEZNOV & B. N. MAKSIMENKO. *Legkie Metallui,* Vol. 4, June 1935, pages 18-26. In Russian. Al dross from foundries and Al_2O_3 were electrolyzed. The alloy obtained contained 0.91-1.5% Cu, 2.26-3.64% Si, and 0.58-2.04% Fe. HWR (2a)

Electrolytic Production of Magnesium Aluminum Alloys from a Cryolite Solution. A. M. ROMANOVSKII & YA. K. BERENT. *Legkie Metallui,* Vol. 4, June 1935, pages 27-40. In Russian. MgO is soluble in molten cryolite but its electrolysis is impractical because mainly Al is deposited, decomposing the electrolyte. HWR (2a)

Progress in Beryllium Concentration and Production of Metallic Beryllium (Fortschritte auf dem Gebiete des Beryll-Aufschlusses und der Herstellung von metallischem Beryllium) R. STRAUSS. *Angewandte Chemie,* Vol. 48, Nov. 30, 1935, pages 745-750. Increasing importance of Be is due to the great hardness, heat conductivity and strength which even a few % confer on the heavy metals, especially Fe, Cu and Ni; Be alone is a strong deoxidizer. The different types of Be ores from which the metal is produced, concentration processes and the production of metallic Be are discussed. A new process according to German patent 563,652 is described by which it is possible to produce Be by distillation; Be oxide is reduced in vacuum in presence of metals of the Cr group (Cr, W, Mo), and the metal condensed on a cold surface. The Be oxide is mixed with coal (or C) and Cr, W, Mo added either in the form of metal or oxide; these added metals act as catalyzers and accelerate the reduction. Ha (2a)

Beryllium (Le glucinium) ROBERT GADEAU. *Revue de Métallurgie,* Vol. 32, Dec. 1935, pages 627-637. Beryl is decomposed by grinding, sintering with Na_2SiF_6, regrinding and leaching with hot water. $NaBeF_3$ solution so produced is saturated with CaO producing BeOCaO, which is treated with HF to form BeF_2 solution. Compagnie Alais, Froges at Camargue, French 742,619, uses the reaction $6NaBeF_3 + 2H_2SiF_6 + SiO_2 = 6BeF_2 + 3Na_2SiF_6 + 2H_2O$ permitting the recovery of all F through reuse of Na_2SiF_6. BeF_2 solution is evaporated and heated to 300° C. to obtain oxyfluoride. When fluoride is desired NH_4F is added to the solution before the evaporation and the temperature is raised to 400° C. Oxyfluoride is electrolysed in Siemens & Halske process at 1400° C. after being diluted with BaF_2 (equal amounts are used). This ratio must be maintained to obtain 80% current efficiency. Higher or lower ratios reduce it pronouncedly. Molten bath is fed with the above mixture to take care of volatilization losses. Na salts must be rigidly excluded because they greatly reduce the efficiency of the operation (Fischer, *Wissenschaftliche Veröffentlichungen aus dem Siemens Konzern,* Vol. 8, 1929). BeO cannot be added as it is not soluble in fluorides. Alloys of Be can be prepared by adding either fluorides of light metals such as Al to the bath or charging chips of heavy metals which fall to the bottom and are converted into fluorides by anodic F. This permits making 40% Cu-Be alloys, alloys with a greater Cu content are heavier than the bath and are liable to fall to the bottom. A list of physical and chemical properties of Be is given. Al-Be, Mg-Be, Ni-Be, Fe-Be, Cu-Be alloy systems are described. JDG (2a)

Chlorine Method for the Treatment of Roasted Copper-Pyrite. D. M. CHIJIKOW & SH. SH. MARGOLINA. *Zhurnal Khimicheskoy Promishlennosti,* No. 8, Aug. 1935, pages 811-818. The chlorination of roasted Cu-pyrite containing 1.43% Cu and 1-1.5 g. Au/t. is described, including the mineralogical and chemical composition of the roasted Cu-pyrite, the condition of chlorination, the leaching, cleaning the solutions from the admixture and extraction of non-ferrous and noble metals. For optimum chlorination the temperature was 100° C. and time of treatment 2 hours; leaching was at room temperature for ½ hr. NA (2a)

The Reduction by Hydrogen of Stannic Oxide Contained in H.-C. Copper. W. E. ALKINS & A. P. C. HALLOWES. *Journal Institute of Metals,* Vol. 56, No. 1, 1935, pages 125-132. Includes discussion. See *Metals & Alloys,* Vol. 6, June, 1935, page MA 221L/6. (2a)

Electrochemistry of Sodium (Die Elektrochemie des Natriums). R. STRAUSS. *Die Metallbörse,* Vol. 25, July 1935, pages 929-930; July 31, 1935, pages 961-962; Aug. 7, 1935, pages 993-994; Aug. 14, 1935, pages 1025-1026. Deals in full detail with the production of Na from caustic soda and with the electrolysis of rock salt. The patent situation is frequently referred to. EF (2a)

Chemical Reactions Between Colloids. I. Copper and Sulphur (Über chemische Reaktionen zwischen Kolloiden. I. Kupfer und Schwefel). E. SAUER & DORA STEINER. *Kolloid Zeitschrift,* Vol. 72, July 1935, pages 35-40. Cu and S sols were prepared in different manners and mixed. A primary reaction leads to Cu(I)sulphide which changes to Cu(II)sulphide gradually or instantaneously at room temperature and on heating respectively. A colloidal suspension of Cu thoroughly freed from the electrolyte was also prepared. EF (2a)

Chemical Reactions Between Colloids. II. Mercury and Sulphur (Über chemische Reaktionen zwischen Kolloiden. II. Quecksilber und Schwefel) E. SAUER & DORA STEINER. *Kolloid Zeitschrift,* Vol. 73, Oct. 1935, pages 45-47. Colloidal Hg-sulphide is formed on mixing Hg and S colloidal suspensions. The reaction is much slower than in the case of Cu and S. EF (2a)

Nature, Formation and Removal of Dust Through the Top of a Blast Furnace as a Function of Constitution of Oolitic Ores (La nature, la formation et l'entrainement des poussières de gueulard, étudiées en fonction de la constitution des minerais oolithiques) J. P. AREND, A. JUNGBLUT & C. ASCHMAN. *Revue de Métallurgie,* Vol. 32, Oct. 1935, pages 363-392. Dust in blast furnace top gases is seldom larger than 1 mm. diameter, most of it being under 0.25 mm. diameter. Up to 85% of the latter is composed of oolites. In minette ores the Fe content of the dust varies inversely with the size of the particles. The Fe content governs the physical properties. Magnetic seperation recovers 49% of the Fe in the dust; after roasting at 700° C. the recovery is 96% Fe. About 1/3 of the dust is charged with the ore, the rest is formed in the furnace. About ¼ of the combined water is eliminated between 100° and 260° C., ½ between 260° and 310° C. and the rest requires heating up to 500° C. Heating in reducing atmosphere dehydration is combined with reduction which is more intense for particles less than 0.25 mm. diameter, being proportional to the temperature. Dust in top gases can be separated into 3 groups according to its magnetic properties which are related to the depth to which the ore had time to settle in the furnace. About 30% of dust is strongly magnetic, containing about 55% Fe, 7% is slightly magnetic and carries 32% Fe, and the rest is non magnetic and has the composition of the original ore. A detailed mathematical analysis of the factors connected with dust removal from the furnace is given. Checking the results in an apparatus imitating conditions met in a blast furnace showed that the weight of dust removed is directly proportional to the kinetic energy of the blast. When the gases are expanded, the weight of dust carried varies inversely with the square of the cross section, the relation being a parabolic function. Friction between gases and walls is greater than theoretically expected because the dust exerts an adhesive power towards the walls which is practically independent of the speed of the gas. The amount of dust removed is directly proportional to the top temperature of the furnace. Knowing kinetic energy of the gases permits the determination of the amount of dust of any dimensions which will be carried away and of the speed at the top which will reduce the quantity of the dust removed to any desired value. The first stages of blowing remove the dust originally present in the ore and that produced by abrasion of hard minette ore. A soft and powdery ore is not necessarily the one which will form the most dust. Kinetic energy of gases in the upper levels of a blast furnace varies with the free section of the charge, volume of water carried and with the drop of temperature due to progressive cooling. To decrease the amount of dust carried away one has to reduce the energy of gases within the charge at critical levels of the blast furnace. It can be achieved by lateral deviation of the gaseous stream by vapor liberated by dehydration of the ore at proper levels. These phenomena occur under the 500° C. level, the critical zone of elimination. JDG (2b)

Material Distribution on Top of Blast Furnaces. N. L. GOLDSTEIN. *Domez,* No. 8, 1935, pages 1-10. In Russian. Stock line of a blast furnace can have either 1 or 2 slopes. In the first case the ridge of material is located at the walls, in the second, at a certain distance from them. With a single slope the fines are located at the periphery, with the double ridge the fines form an intermediate ring between large pieces concentrated at the walls and in the center. Position of the ridge has a pronounced influence on the resistance of the charge. With the same opening of the cone and the same height of the stock level the distribution of charge particles depends on their size. Mathematical analysis gives the means for calculating the distribution of different size fractions in the furnace. (2b)

Treatment of Iron Ore Fines. C. SAINT-JACQUES & L. POUPET. *Iron & Coal Trades Review,* Vol. 131, Dec. 13, 1935, pages 982-983. Saint-Jacques process was developed for treating Fe ore fines and blast furnace dust and consists in subjecting the fine material to an extremely high temperature, each separate grain being in suspension and in motion, eddying in a mass of flame, so that heat is transmitted to every particle under most favorable conditions. The dust is injected tangentially into the upper part of a furnace of the shaft type; air inlets at different levels provide the necessary motion of the gas. Tests over 12 months are described. Ha (2b)

Qualities of Pig Iron. *Metals Technology,* Jan. 1936, *American Institute Mining & Metallurgical Engineers Technical Publication* No. 669, 16 pages. A round table discussion held in Chicago in October 1935, dealing with the quality of pig Fe as separate and distinct from chemical composition. One member claimed that pig Fe was sometimes received in the foundry that after melting did not make satisfactory castings even though it had a composition similar to Fe that made satisfactory castings. A considerable part of the discussion was devoted to blast-furnace practice. JLG (2b)

New Results in the Compressed Air Roasting of Westphalian Siderite (Neuere Ergebnisse bei der Druckluftröstung des Siegerländer Spateisensteins) H. GLEICHMANN. *Stahl und Eisen,* Vol. 55, Oct. 31, 1935, pages 1164-1165. Increasing the air pressure materially improved the output of the furnace. SE (2b)

Sintering of Fluedust and Fine Ore in a Shaft Furnace (Sintern von Gichtstaub und Feinerz im Schachtofen) J. W. GILLES. *Stahl und Eisen,* Vol. 55, Nov. 7, 1935, pages 1188-1190. Sintering of flue dust and fine ore in a shaft furnace is possible; large outputs can be attained although smaller furnaces are preferable. SE (2b)

Cleaning of Blast Furnace Gas in Whirlers (Vorreinigung von Gichtgasen in Wirblern) W. BARTH. *Stahl und Eisen,* Vol. 55, Oct. 24, 1935, pages 1129-1134. Through the use of whirlers instead of the usual dust bags much better cleaning of blast furnace gas can be obtained. Calculations are given for determining the cleaning effect of both. SE (2b)

3. MELTING, REFINING AND CASTING

The Expansion and Contraction of Molding Sand at Elevated Temperatures. H. W. Dietert & F. Valtier. *Transactions American Foundrymen's Association,* Vol. 6, Dec. 1935, pages 107-122. Good foundry practice dictates a study of the behavior of the molding material under thermal changes. The contraction and expansion of molding sands have been investigated and it is shown that fineness, clay content, moisture, sea coal and mold hardness exert important effects on these 2 properties. Molding sands with improper expansion and contraction properties often are responsible for such defects as rat-tails and scabs. The dilatometer apparatus used for the testing is described. It is concluded that the expansion of molding sand may be reduced by increasing grain size, reducing the fines, addition of combustible materials, reducing the mold hardness, increasing permeability, or reducing moisture. The opposing stresses between expansion and contraction may be reduced by increasing grain size, reducing fines, reducing mold hardness, increasing permeability, reducing moisture, or reducing the clay content. Cupola Furnaces in Brass Foundries (Zur Verwendung von Kupolöfen in Messinggiessereien) E. R. Thews. *Giesserei,* Vol. 23, Mar. 13, 1936, pages 135-136. American view that the cupola furnace is suitable for melting brass is not shared by the author who brings forward several reasons for lack of adaptability of this furnace to the special requirements of brass melting, among others the contact of the brass with noxious gases, coke and ash particles, necessity for an expensive fuel, high Zn losses, impossibility of obtaining the best pouring temperatures, and the necessity for installing a plant for the recovery of the Zn oxide. Also the first cost of a cupola furnace is high. Ha (3a)

The Effect of Gases on Formation of Pores When Casting Copper Alloys (Der Einfluss von Gasen auf die Porenbildung beim Giessen von Kupferlegierungen) E. Raub, F. Distel & M. Marchand. *Giesserei,* Vol. 23, Feb. 28, 1936, pages 111-114. While molten Cu, in general, absorbs gases (H, SO_2, CO_2, CO), which are liberated again on cooling, the Cu alloys behave differently. Addition of Zn makes castings dense, 1% Zn was sufficient for the almost entire exclusion of H, steam and CO_2. Castings can hardly be porous as no freeing of gases takes place which had been absorbed in molten state. Cu-Al alloys become denser with increasing Al content, and solubility of H decreases. Cu-Al melts react strongly with water vapor and CO_2, they also slag appreciably with low Al contents. The specific gravity of Cu-Sn alloys increases greatly with the Sn content; it is lowest for the alloys treated with H. Melts with more than 1% Sn treated with CO_2 and SO_2 are practically free from pores; water vapor produced pores even at higher Sn contents. Sn-Ni alloys show at first a strong increase of porosity with Ni content when treated with water vapor. CO_2 reduced the specific gravity of alloys with more than 5% Ni, due to absorption of considerable amounts of gas in the melt which is liberated again on solidification. 15 references. Ha (3a)

The Vacuum Distillation of Metals. Part II. Refining Tin and Lead by Evaporation in a High Vacuum. W. Kroll. *Metal Industry,* London, Vol. 47, Aug. 16, 1935, pages 155-156. In his experiments with Sn the author melted the metal in a sintered alumina crucible and the vapor was precipitated on a hood of the same material. Temperature could only be estimated as the Ribaud high frequency furnace precluded the use of a thermocouple. Both the distillate and the residue were analyzed. While only Katanga Sn was used in these experiments, from the data obtained, it appears that the most objectionable impurities in Bolivian Sn might be removed by distillation. In the experiments with Pb both the crucible and the condensation hood were of Fe. The melts were made in the Lorenz high frequency furnace which made it possible to use thermocouples for temperature measurement. Special precautions were taken to prevent contamination of the residue by material that had been volatilized. The method appears to be satisfactory for the elimination of Pb and As from Sn and of Zn from Pb. Other impurities are partially eliminated. HBG (3a)

A Million and a Half Brass Die-castings Yearly. Chas O. Herb. *Machinery,* N. Y., Vol. 42, Feb. 1936, pages 361-366. Principal advantages of brass die-castings over sand castings are better appearance, greater strength, more uniform cross-sections due to less likelihood of blow-holes, and more economical production in large quantities. The Polak machine is described in which the compression chamber is arranged in the die. Hydraulic pressure up to 5500 lbs./in.² is applied. Examples are illustrated. Ha (3a)

"The Tops" in Sand Blasting

For better, more economical cleaning we offer Mineral and Metallic Abrasives, scientifically processed in America's largest abrasive producing plants, giving us a continuous supply of uniformly dependable grades of abrasives best adapted to take care of every type of casting or material to be cleaned.

We are serving plants throughout the United States and Canada, and at regular intervals our service engineers make calls on them giving sound, practical advice on equipment and methods that invariably result in lasting economies.

Sand blasting costs are further minimized by the use of Stoody-Borium (the hardest of all tungsten carbides) and Great Lakes Alloy Iron Nozzles. They cost less and wear longer.

If you are not already a Great Lakes customer let us prove by practical demonstration our ability to increase the efficiency and reduce the costs of your sand blasting department.

Return this advertisement with your firm name and we will show you how.

Recommended Practice for Sand Cast Aluminum Alloys. Report of Non-Ferrous Division Committee on Recommended Practices. *Transactions American Foundrymen's Association,* Vol. 6, Dec. 1935, pages 1-26. In preparing these recommendations the Non-Ferrous Division of the A.F.A., through its Recommended Practice Committee, has attempted to collect through reliable sources, such information as will be of practical use to the foundrymen handling nonferrous alloys. These present recommendations are the first of a contemplated series on various groups of nonferrous alloys. Although the various practices which are treated are recommended by those considered specialists in the various fields, these practices are not intended as specifications. This first report is limited to Al alloys. General recommendations as to molding, melting and pouring, finishing, heat treatment, and defects are given. Recommended practices consisting of a discussion of chemical control limits, physical properties of castings, conforming specifications, development and fields of use are given for the following alloys: Al-Cu, heat treated Al-Cu, Al-Si, heat treated Al-Cu, and Al-Mg. CEJ (3a)

Recovering Tin from Soldered Sections. C. C. Downie. *Machinery,* London, Vol. 47, Feb. 6, 1936, page 555. General discussion of removal of Sn from tinned scrap Fe, Cu and brass by immersion in molten Pb. The solvent action of Pb on the Sn is enhanced by adding As to the bath which then deposits on the surface of the Fe or Cu scrap and tends to drive off the Sn into the Pb. Other alternative is to melt down the composite Fe Cu scrap on top of a bath of arsenical Pb. Concentration of Sn from bath is briefly reviewed as partial oxidation to obtain Sn-rich dross which is then converted to solder by reduction. WB (3a)

Magnesium and Its Ultra-light Alloys (Le Magnésium et les Alliages Ultra-Légers) Paul Bastien. *La Technique Moderne,* Vol. 28, Jan. 15, 1936, pages 39-41. Melting, refining and casting are discussed. FR (3a)

Equilibrium in Lead Smelting. S. Frederick Ravitz & Kenneth E. Fisher. *American Institute Mining & Metallurgical Engineers, Technical Publication,* No. 681, Feb. 1936, 7 pages. In the Pb blast furnaces 4 liquids are present; Pb bullion, speiss, matte, and slag. In order to determine whether or not these 4 phases are in equilibrium, crucible melts were made and the layers analyzed for Au and Ag. The materials used were dross-furnace products and Au and Ag salts were added. When different amounts of the precious metals were added it was found that their ratios in the different layers was constant, thus indicating that equilibrium had been reached. JLG (3a)

The Production and Control of Bronze Castings. Francis Rowe. *Aluminium & the Non-Ferrous Review,* Vol. 1, Nov. 1935, pages 74-75. Read before the Midland Metallurgical Societies. A general lack of density, resulting in poor physical properties, is the most prevalent trouble in bronze castings. Melting methods must be considered carefully; the Ajax Wyatt furnace appears the most promising for the highest quality castings. Centrifugal castings have a higher density and are stronger than sand castings. JCC (3a)

Application of Metallographic Theory to the Refining of Metals. Hideo Nishimura. *Suiyokwai-Shi,* Vol. 8, Dec. 1935, pages 851-858. Author discusses process of refining of pure metals such as Parks or Patinson process by applying the theory of heterogeneous equilibrium. Probable ternary diagrams to be applied in the removal of impurities from pure metals are explained and some suggestions concerning the metallurgical refining process are given. HN (3a)

Manufacture of Copper Tubing. Otto Z. Klopsch. *Iron Age,* Vol. 136, Dec. 19, 1935, pages 24-27, 86. From a paper read before non-ferrous section of the Detroit chapter of the American Society for Metals. Describes the manufacture of 99% Cu tubing by the Wolverine Tube Co. Metal is melted in tilting furnace under carefully controlled conditions. Molten Cu is kept under charcoal blanket to prevent absorption of excessive amounts of O_2. When pouring temperature is reached P-Cu is added to deoxidize charge. Charge is poured directly into billet mold. After cooling billet is headed by ladle addition of molten Cu. Billets are heated to extrusion temperature in oil fired muffle furnace. Heated billets are upset by a special device to insure snug fit. After 2 or 3 passes through die tube is annealed to refine grain structure. Bright annealing of tubes is done in General Electric furnace. Tubes used for refrigerant, gasoline or oil must be free from scale and moisture. VSP (3a)

Electrolytic Solder. R. P. E. Hermsdorf & Max Heberlein. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 680, Feb. 1936, 9 pages. Pb-Sn alloys obtained from scrap are refined electrolytically and made into high-grade solder. The impure alloys are first fire refined to reduce Cu content and contents of some other impurities. The semi-refined alloy is cast into anode plates and electrolyzed in a Sn-Pb fluosilicate solution. The usual anode analysis is 62% Pb, 35% Sn, 2% Sb, 0.25% As, 0.05% Cu, 0.05 oz./ton Au, and 30 oz./ton Ag. A residual anode slime that adheres to the anode but does not make it passive is produced. Insufficient H_2SiF_6 causes hydrolization of $SnSiF_6$. The electrolyte is circulated over shot of 30 Sn-70 Pb to cement out impurities. No attempt is made to produce cathodes of definite Sn and Pb contents. The cathodes produced are analyzed and melted with either virgin Sn or Pb to make solder of the desired analysis. The Sb content of the electrolytic solder averages 0.02%. JLG (3a)

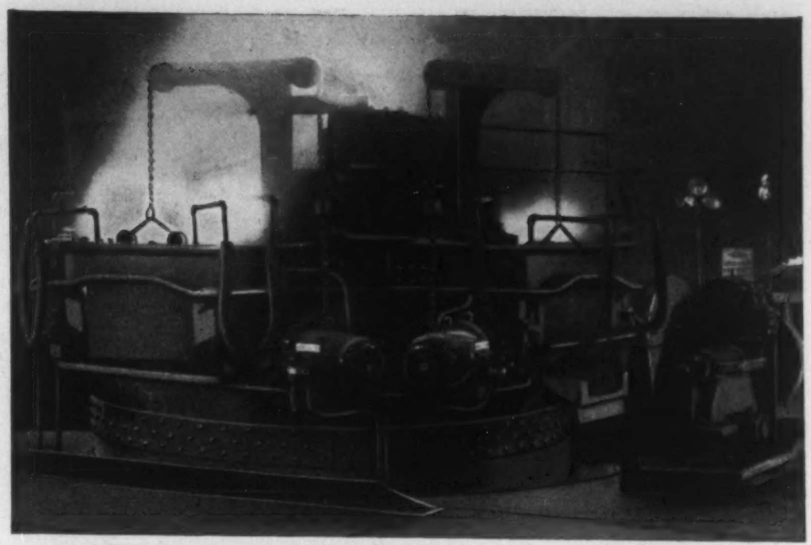
Working Conditions Inside of an Open Hearth Furnace. I. D. SEMIKIN. *Domez*, No. 8, 1935, pages 10-25. Life of furnace walls and roof depends on the equilibrium between heat supplied and radiated from them, being independent of the temperature of the flame. Thermal load on the roof is not uniform. Along the length of each roof is present an area which has a higher temperature than the rest of the wall and where failures start under normal operations. Width of flame is usually about ⅓ the width of the bath. A narrower, hotter flame can produce the same results. Small decrease in temperature of the flame requires increasing its width several times to get the same heat supply. Greater efficiency is usually obtained when the flame is farther from the roof. Mathematical study of heating phenomena in the melting zone shows the possibility of overheating the bath above the roof by about 20° C. max., impossibility of overheating the bath above the temperature of an insulated roof and the advantage of thin roofs and walls for introducing in the furnace more heat per unit of time when the flame has the required heat capacity. Increasing flame temperature does not produce a higher temperature in the bath, but increases sharply the heat transfer to it without harming the furnace. When surface temperature of bath is under the temperature of roof, heat transfer per unit of bath surface is not affected by the amount of insulation of the furnace. High flame temperature cuts down by about 25% the amount of fuel per ton of metal, and shortens the time of heat about 10% by reducing time for melting down. Chemical reactions between the molecules of hot gases take place instantaneously. Speed of combustion depends only on the rate of mechanical mixture of air with gases. Flame of an open hearth furnace cannot be the result of burning a mixture already formed. It is composed of two separate streams of gas and air. Turbulency of streams is the major factor affecting speed of combustion. Outside eddies produce larger surfaces along which contact of air with gas occurs. Air and gas travelling in parallel high velocity streams create the best combustion conditions. Each section of the flame along the whole length of the furnace receives here a fresh supply of air from its primary source, the parallel stream of air. Good efficiency of such ports as Moll or McCune does not depend on a preliminary mixture, but on the instantaneous formation of an insulating layer of combustion gases between air and gas streams and on the high velocity with which the parallel streams enter the furnace. Present speeds, particularly in larger furnaces, are entirely inadequate. Life of their roofs is about half as long as in smaller ones. Large angle with the horizon used for the present air ports only interferes with oxygen supply in the second half of the furnace while the first gets its oxygen anyway. 3 types of the wear of roofs are often observed. They can be worn in triangular section along the back wall, in a long band parallel to the axis of the furnace and particularly pronounced in the second half of it, or uniformly all over the roof. In the first case, a powerful stream of air moves downwards at an angle of 30°-45° on the stream of gas. It has a pronounced inertia and creates an aspirating effect between itself and the roof. Gaseous stream moves slowly and does not have a sufficient inertia to overcome damming effect produced by the air. It is broken, and portions of it are squeezed out at the sides rising along the periphery of the furnace to the areas of partial vacuum. Though the phenomenon is not strictly localized, it recurs frequently enough in the same spots to groove the roof in the manner described. Cutting down the inertia of air by limiting its supply leads to the burning of ports. In the second case air stream moves slowly but gas has a high speed. On impinging on the bath surface air loses more of its speed and slowly moves along the furnace gradually mixing with the gas and burning. It does not have sufficient inertia to follow the flame and rises to the roof overheating it. The second half of the furnace is insufficiently supplied with oxygen unduly lengthening the flame and burning ports and uptakes. Destructive effect is more pronounced the lower the gas speed, the greater the angle of air ports and the longer the furnace. Third type of wear is associated with a proper proportioning of gas and air with the length of the furnace. Gas stream must be the major factor controlling the motion of the furnace atmosphere, if a long roof life is desired. Air stream must assist it. Angle of inclination of air ports always has a negative effect on the control of the motion of gases in the furnace. Doubling length of a furnace calls for a practical doubling of gas and air speeds. Small furnaces last longer because their speed of gas, 4-9 m./sec. and of air, 1.5-3.5 m./sec. (German practice) are kept the same for larger furnaces, instead of being 8-10m./sec. for gas and at least 0.7 of this value for air. Dimensions of the ports should not be designed on the basis of average fuel consumption, but on the fuel consumption during the finishing of the heat. This is associated with a uniform speed of the gas stream. During the charging period its heat capacity can be increased by additional burners. The arrangement will lead to changing loads on gas ports, but these can be taken care of by a proper stack. In the first half of the furnace gas stream receives about ½ the air used for its combustion from the sides. This permits the protection of roof by locating the air ports in the horizontal plane according to Venturi principle and building the ports with a slight elevation to the roof instead of the usual inclination in the opposite direction. The arrangement tends to increase the efficiency of the flame. (3b)

Non-Metallic Impurities in Open-Hearth Steel. FOLKE W. SUNDBLAD. *Iron Age*, Vol. 136, Nov. 14, 1935, pages 21, 76-77. Certain chemical reactions in steel bath produce surface disturbances known as boils. There are 3 types of boils, namely lime and ore boils, and bottom boil which distinguishes itself from the others in appearance. Slag fluidity influences oxidation and therefore the speed of oxidation is materially in direct proportion to the fluidity of slag. This becomes of special significance when making a large high-C heat. Instantaneous deoxidation of large bath is likely to entrap foreign impurities to far greater extent than smaller unit with low temperatures and slow oxidation. By study of bottom boil the direct causes are primarily physical, as the attack upon the bottom is almost entirely due to temperature of metal, which is dependent upon the oxidation of its C. Next important step in evolution of open-hearth steel is to change the working methods of tonnage unit, based on entirely different speed of oxidation than that used by smaller furnace, where quality is main object and time element of minor importance. VSP (3b)



HEROULT *Electric* FURNACES

USE them for efficient melting and refining of all kinds of ferrous materials by either basic or acid process—including Alloy Steels, Tool Steels, Forging Steels, Steel and Iron Castings. Any capacity from ½ ton to 100 tons; removable roof, chute, machine or hand charging.

Cast Iron Pulleys for Wire Ropes. *Foundry Trade Journal,* Vol. 53, Dec. 12, 1935, pages 433, 434. Extract from the report of the Wire Ropes Research Committee. Some users favor chilled-iron pulleys for wire ropes. It is very difficult to justify this view, because a hard surface to the pulley tread would appear to lead to greater resistance to indentation by the wires, with greater bearing stress between the wires and the pulley, and also, probably, greater bending stress. A certain amount of bedding of the wire into the metal groove must give an increased bearing area, and probably relieves the sharpness of the bend where it is most severe, at the inner side of the rope adjacent to the pulley. It is not possible to cast chilled-iron pulleys to fit the ropes, nor is it practical to grind the grooves. It was also shown that a rope had a longer life when it was used dry than when it was lubricated. Many tests were made to compare the life of ropes on chilled and on ordinary cast-iron pulleys. It has been shown that chilled-iron pulleys do not permit so long a rope life as cast-iron pulleys. The Committee has also investigated the relationship between rope and the material used for the pulley groove. Similar pulleys were cast in different metals, and in addition cast-iron pulleys were made with an under-cut groove which could be filled with appropriate materials. All pulleys were grooved to fit the rope in use and the ropes were lubricated. The test results and other data are given in 4 tables. Plastic wood seems to be very satisfactory as material for pulley grooves.
AIK (3b)

Adopts Test Block Control. Henry P. Biegel. *Foundry,* Vol. 63, Nov. 1935, pages 31, 82. Describes a useful method for testing the quality of Fe at casting time. Principle of test is based on Si content of Fe which is reflected by depth of chill or lack of it. Test block used is ¾″ x 2½″ x 5″ and is poured with narrow face against a chill and in open mold. When cooled to a dark red it is quenched slowly in oil and cooling finished in H_2O. Quality of Fe is indicated by characteristic appearance of fracture. Method is useful in any type of gray Fe foundry.
VSP (3b)

Suggested Improvements in Purchase Requirements for Important Steel Castings. Charles W. Briggs. *Journal American Society of Naval Engineers,* Vol. 47, Nov. 1935, pages 532-537. Casting design is based on accumulated practical experience rather than the application of design fundamentals. Author ascribes unsoundness in steel castings to this cause rather than to poor foundry technique either in molding or steel melting. A number of critical questions are put as to the control of solidification in the casting. The case of the U. S. Navy in awarding contracts for steel castings is taken up and criticized because cognizance is not taken of the availability to the lowest bidder of equipment necessary for producing sound castings. γ ray inspection is mentioned as important non-destructive test for checking casting unsoundness, and its use by manufacturers is suggested for improving quality. Author suggests preparation of government list under several headings such as turbine casings, high pressure steam castings, etc. for manufacturers of preferred acceptability, inclusion on the list to be conditional upon passing government inspection of pilot casting made by the company.

Aluminum Additions in Modern Commercial Steels. H. W. McQuaid. *Metal Progress,* Vol. 28, Nov. 1935, pages 33-37, 78; *Transactions American Society for Metals,* Vol. 23, Dec. 1935, pages 797-838; *Steel,* Vol. 97, Oct. 14, 1935, pages 45-46; *Iron Age,* Vol. 136, Oct. 10, 1935, pages 20-27; Oct. 17, 1935, pages 28-34, 84, 86, 88. Tenth Campbell Memorial Lecture delivered at A.S.M. convention, Chicago, 1935. From an addition primarily made to quiet wild heats and supposedly harmful in effect Al has become most important factor in production of uniform hardenability and grain size in steel. Tendency of Al to produce fine grain and shallow hardening is much more pronounced than effect of Mn in opposite direction. Mn and Ni tend to stabilize the austenite and make ferrite more rigid reducing the tendency to coalesce the carbide. An active carburizer which builds up carbide at surface faster than austenite can absorb it tends toward a retention of fine grain. It is found that the Al addition to produce the characteristic effect is less for low O_2 metal than high O_2 metal (electric steel than open hearth). The effect of Al is therefore suggested to be one of decreasing the solubility for carbide thus promoting coalescence of carbide and its attendant effect to impede grain growth. This effect will be felt regardless of the presence of deep hardening additions (of Mn) if Al is appropriately high above that required to deoxidize. The experimental data on 42 special heats are reported in full in the complete lecture in the *Transactions. Metal Progress* contains only an abstract and discussion of conclusions and theory.

Open-Hearth Insulation Advances. *Steel,* Vol. 98, Jan. 6, 1936, pages 240, 336-337. Presents opinions of several authorities as to important developments in steel making in 1935. Includes use of Cu molds and stools; new types and methods of furnace insulation; new devices for control of furnace atmosphere and roof temperature; new types of furnace design; continued interest in grain size control and slag control; new types of soaking-pits; improved fire-clay nozzles; and magnesite stoppers for pouring special steels.
MS (3b)

Making Stainless Bimetal. Ya S. Ginzburg, M. B. Katzenelenbogen & V. S. Lurie. *Kachestvennaya Stal,* No. 8, 1935, pages 27-34. In Russian. Method for making bi-metal sheets by casting soft steel around 2 plates of stainless steel placed in ingot molds proposed by the authors is described. Properly cleaned sheets of stainless steel are coated on one side with a slurry of burned MgO and dried to form a coating 0.2-0.3 mm. thick. Coated surfaces are placed side by side and the sheets are either clamped together mechanically or welded around their periphery. 4 clamps are required for one meter sheets. Packets so produced are suspended in ingot molds to be fully immersed in the metal. Welding of sheets takes place in rolling, and is better with longer time of soaking at high temperatures. Rolling practice and roll design used for production of common sheet bar are suitable for bi-metal rolling. Normalization at 1050° C. does not produce coarsening of grain in soft steel layer as drawing and quenching do. Pickling in 47% HCl, 5% HNO_3, 48% H_2O without any inhibitor affects both layers approximately equally. The use of an inhibitor caused overpickling of soft steel. See also "Electrolytic Iron Provides Bond in Cladding with Special Alloys," R. R. Rogers, *Steel,* Vol. 98, Feb. 10, 1936, page 34.

Research on Cast Iron. *Engineering,* Vol. 140, Nov. 15, 1935, pages 531-532. From the fourteenth annual report of the British Cast Iron Research Association. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 56R/6.
LFM (3b)

Open Hearth in 1935. K. C. McCutcheon. *Blast Furnace & Steel Plant,* Vol. 24, Jan. 1936, pages 47-49. Summarizes progress and changes of the year. These include attention to open-hearth fuels; savings in fuel and protection of brickwork by automatic control of fuel and air; use of pyrometers to control tapping, pouring, and roof temperatures; increased use of insulation; use of many new ladles of welded construction; higher mold life; improved design of existing furnaces; better bricks for special furnaces; increased size of heats tapped; better refractories; increased use of slag control; and improved pouring equipment.
MS (3b)

An Up-to-Date Foundry Layout. A. B. Jacobus. *Iron Age,* Vol. 137, Jan. 16, 1936, pages 26-27. Describes the foundry layout of the Fairbanks Scale Works in St. Johnsburg, Vt. Greatest savings have been made in production of castings for the bases of portable scales. Brass and Al castings are made in an adjacent foundry. Continuous pouring system is used throughout the foundry. Illustrates layout of Fe foundry.

Advantage of a Melting Sheet for Starting an Electrical Steel Furnace Installation (De l'utilite d' un diagramme de marche pour la mise en route d'une installation de four électrique à acier). E. Decherf. *Journal du Four Electrique,* Vol. 44, Nov. 1935, pages 395-398. When breaking in inexperienced furnace operators a predetermined melting sheet is advantageous. An example of one is given.
JDG (3b)

Copper Stools for Ingot Molds. Clyde E. Williams & H. B. Kinnear. *Metals & Alloys,* Vol. 6, July 1935, pages 169-172; Aug. 1935, pages 213-217; correction to Fig. 16, Nov. 1935, page 331. The higher thermal conductivity with faster removal of heat from the molten steel justifies and makes economical the use of Cu stools for steel ingot molds. Cu used is "tough pitch" containing 0.04% O_2 and is cast in slabs or cakes in water cooled molds to obtain a smooth surface requiring no machining. Experience indicates Cu stools should weigh 2/3 the ingot weight, that thickness should be at least 1/55 the bottom area of the ingot, that peening of small thermal cracks as they appear postpones failure, that laminated stools made of Cu bricks set in cast iron frame or Cu inserts in Fe stools are advantageous in reducing Cu scrap. Crediting stools only with scrap value of Cu returned means stools should give a life of 500 heats. The first Cu stool in commercial use has gone 900 on one side and 600 on the other side. Many others still in use have passed 500 heats. These were massive stools and peening was not employed or other precautions taken. Cu stools are evidently economical. Other savings are effected, bulging of the bottom of the ingot is eliminated, rejections are normal and mold life is increased 30-100%. Temperature measurements in stools and molds are reported and indicate much more rapid cooling from the bottom with little difference further up the mold. This is the critical location with regard to ease of stripping. Experimental work on all Cu molds is encouraging but incomplete.
WLC (3b)

4. WORKING

Changing Practice in the Use of Oil in the Forming and Cutting of Metals (Umstellungsmassnahmen bei der Oelverwendung in der spanabhebenden und spanlosen Formgebung der Metalle) K. Krekeler. *Zeitschrift für Metallkunde,* Vol. 27, Nov. 1935, pages 262-263. Because of the increasing scarcity of the vegetable and animal oils which have in the past been used in the forming and cutting of metals, the substitution of special mineral oils is being practiced. Mineral oils which leave no residue or blemish on rolled or drawn metal after working and annealing are now available. The corrosion and staining of hot rolled metals by the use of cooling water on the rolls is being retarded by the introduction of a special mineral oil into the water. Vaseline is being used in the drawing of Al wire and emulsified mineral oils are being employed for the cutting of metals. No specifications for the oils are given. FNR (4)

Recent Advances in Pressure-Forming Processes. H. Haake. *Engineering Progress,* Vol 17, Jan. 1936, pages 1-5. Recent atomic research and the new concepts relative to structure and properties of crystals have effected great changes in the processes of forming and deforming metals and other materials which are used in pressed form in industrial operations. Hot and cold working processes for metals and artificial resin products are discussed. 29 references. Ha (4)

4a. Rolling

RICHARD RIMBACH, SECTION EDITOR

Effect of Material of Roll, of Rolling Velocity, Width of Strip and of a Preceding Cold-deformation in Cold-rolling of Strip-steel (Der Einfluss des Walzenwerkstoffes, der Walzgeschwindigkeit, der Bandbreite und einer voraufgegangenen Kaltverformung beim Kaltwalzen von Bandstahl) Werner Lueg & Anton Pomp. *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Vol. 17, No. 20, 1935, pages 219-230. Exhaustive tests permitted drawing the conclusions that for the same quality of the roll surface, the material of the rolls has no effect on the rolling process. The rolling velocity did not show any effect in the range of speed change from 1:130. The effect of the section of material to be rolled is such that the roll pressure increases with the width of the strip linearly for the same reduction. Above a ratio of about 15 between width and thickness of the strip, no effect of the width could be observed. The structural state of material has also some influence; for the same reduction rolling pressure and resistance against deformation increase with the degree of preceding cold-deformation at first rapidly and then slower. For reductions more than 20%, both quantities increased more sharply again, due to the flattening of the roll surface with the increasing strengthening of the material by cold-deformation. Test curves illustrate the conditions. 10 references. Ha (4a)

New Light Bar Mill in Zig-Zag Layout (Neuzeitliches Feinstahlwalzwerk in Zickzackanordnung) E. Weber. *Stahl und Eisen,* Vol. 55, Sept. 26, 1935, pages 1029-1031. A new light-bar mill with ten 2-high roll stands; the first 6 stands are continuous, the rest in zig-zag arrangement. The layout with furnaces, rolling mills, and auxiliary appliances, is described. The capacity is 20,000 tons per month. SE (4a)

Progress in the Knowledge and Practice of Plastic Forming. II. Rolling (Fortschritte in der Erkenntnis und Handhabung der Verfahren zur bildsamen Formgebung. II. Walzen) E. Seibel. *Metallwirtschaft,* Vol. 15, Jan. 31, 1936, pages 103-107. A historical treatment of the progress made toward an understanding of (a) the power and mechanical requirements of rolling, (b) the flow of material, and (c) a theory which will explain all observed phenomena and predict those which will result from any change in practice. The discrepancies between actual power consumption and that required by simple theory promoted research along all related lines. Methods of accurate measurement and analysis of rolling processes were developed and have provided a basic understanding of the relations between such factors as roll diameter, thickness of material, amount of reduction, temperature of working, friction between rolls and work, and deformation of rolls. But the exact control of all processes, especially the production of complex forms, requires still further advances of theory and practice. GD (4a)

Straightening Machine for Finest Sheets (Feinstblechrichtmaschine) L. Reichert. *Aluminium,* Vol. 18, Feb. 1936, pages 48-50. Principle and types of multiple roll machines for thin sheets are described; the straightening velocity is 5-6 m./min. Ha (4a)

Effect of Rolling Conditions on the Cold Rolling of Strip Steel (Der Einfluss der Walzbedingungen beim Kaltwalzen von Bandstahl) W. Lueg. *Stahl und Eisen,* Vol. 55, Oct. 17, 1935, pages 1105-1112. The rolling speed is without appreciable influence; with hardened Cr steel or white cast Fe rolls the type steel rolled is also of small influence; the important factors are the rolled section, friction, and degree of reduction. Care should be taken in lubricating, polishing, and getting hard surface on the rolls. SE (4a)

Experiences with the Roll Pressure Tester "Pasopos" (Erfahrungen mit dem Walzendruckprüfer "Pasopos") Werner Lueg & Anton Pomp. *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Vol. 17, No. 19, 1935, pages 213-218. The new instrument measures the deflection in rolling of the lowest point of the crown of the lower roll in a roll stand. A definite ratio between this deflection and the sum of the roll bearing pressures was found. Tests made in rolling of different steels are described. Ha (4a)

Roll Design for Structural Shapes (Ueber das Kalibrieren von Formstahl) C. Holzweiler & T. Dahl. *Stahl und Eisen,* Vol. 55, Oct. 10, 1935, pages 1081-1086. Roll design for various H-beams is discussed. SE (4a)

Engineering Developments in 1935. Ralph [H.] Wright. *Blast Furnace & Steel Plant,* Vol. 24, Jan. 1936, pages 65-66. Deals with installations of rolling-mills and auxiliary equipment, with chief attention to electrical equipment. MS (4a)

Hot Rolled Sheet Packs Are Delivered to Shears by System of Conveyors. *Steel,* Vol. 98, Feb. 17, 1936, pages 59-60. Brief description of conveyor system which serves a combination-type sheet mill and minimizes manual handling of sheets to squaring shears. MS (4a)

Co-ordinated Design and Operation Feature McDonald Hot Strip Mill. *Steel,* Vol. 98, Feb. 24, 1936, pages 32-37, 57. Describes 4-high 43″ continuous hot-strip mill recently completed at McDonald, Ohio, plant of the Carnegie-Illinois Steel Corp. MS (4a)

Production of Tubes in Austria (Die Röhrenerzeugung in Österreich) *Montanistische Rundschau,* Vol. 28, Feb. 16, 1936, 4 pages. A description of the Ternitz tube mill of the Schoeller-Bleckmann Stahlwerke A.-G. This plant produces tubes up to 114 mm. diameter. It has a power consumption of 12,000 kw. 2 open hearth Martin furnaces, 3 electric furnaces, and 1 high frequency crucible furnace are used. The annual capacity of the plant is 18,000 tons, 300 men being employed. Drill steel is also produced in addition to tubes. BHS (4a)

Universal Plates for Fabricated Steelwork. *Engineering,* Vol. 141, Jan. 3, 1936, page 10. Illustrated article describing the rolling mill of Messrs. Dorman, Long and Company, Limited, Middlesbrough, England. LFM (4a)

The Hot Rolling of Sheets. *Aluminium & the Non-Ferrous Review,* Vol. 1, Nov. 1935, pages 53-55. Open discussion held by Midland Metallurgical Societies. Chief problems of sheet rolling are to secure uniformity of thickness and a good surface free from scale. To secure uniformity, sheets are often rolled in "packs," shuffling the order frequently. To remove scale from Cu, one suggestion made in the discussion was to use soluble oil for quenching after hot rolling. JCC (4a)

McDonald Mill of the Carnegie-Illinois Steel Corporation. *Blast Furnace & Steel Plant,* Vol. 24, Mar. 1936, pages 224-230, 234. **Coordinated Design and Operation Feature New Rolling Mill.** *Iron Age,* Vol. 137, Feb. 20, 1936, pages 44-45, 74. Detailed description of 43″ continuous hot strip mill and auxiliary equipment at McDonald plant near Youngstown, O. VSP + MS (4a)

Modern Developments in Cold Rolling Mills. C. E. Davies. *Metallurgia,* Vol. 13, Jan. 1936, pages 79-81; Feb. 1936, pages 107-108. General review of up-to-date mills, including those used for ferrous and non-ferrous materials. JLG (4a)

Investigation of the Power Consumption in a Blooming Mill (Untersuchungen über den Arbeitsaufwand beim Blockwalzen) H. Hoff & T. Dahl. *Stahl und Eisen,* Vol. 55, Nov. 7, 1935, pages 1182-1188. Earlier results were confirmed. The composition of the work and particularly the roll design affect the power consumption. SE (4a)

4b. Forging & Extruding

A. W. DEMMLER, SECTION EDITOR

Flakes in Forged Steel (Les "flocons" dans les pièces d'acier forgées) Leon Guillet & Marcel Ballay. *Revue de Mètallurgie,* Vol. 32, Nov. 1935, pages 522-530. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 116R/7. JLG (4b)

The Upsetting of Aluminum and Aluminum Alloys (Das Stauchen von Aluminium und Aluminium-Legierungen) A. v. Zeerleder, R. Irmann & E. v. Burg. *Aluminium,* Vol. 18, Feb. 1936, pages 41-48. The specific upsetting energy was determined and is shown in spatial diagrams for Al and several Al alloys, as a function of temperature and amount of alloying element. Very great differences exist both among the Al alloys and the heavy metals and Al alloys, as the table shows:

Material	Specific upsetting pressure for 50% upsetting in kg./mm.^{2}	working temperature in °C.
Pure Al, 99.5%	1.3-0.8	500-550
Brass	2.0-0.8	700-800
Anticorodal	2.8-1.9	450-500
Cu	4.0-2.6	700-800
Avional D	4.1-3.8	420-440
Peraluman 2	4.8	420-440
Iron	5.0-4.0	1000-1100
Peraluman 3	5.0	420-440

The upsetting velocity and frictional forces have a great influence; the tests were made with an average speed of 60 sec. for a 50% upsetting. Ha (4b)

Forged-steel Die-block Department of Messrs. Thos. Firth and John Brown, Limited. *Engineer,* Vol. 161, Feb. 28, 1936, page 239; *Engineering,* Vol. 141, Feb. 28, 1936, page 229. The company's new plant at Sheffield consists of gas-fired furnaces for reheating, normalizing, hardening and tempering, an oil-quenching tank and tools for making parallel-sided and tapered die blocks. An output of 2 tons per shift is maintained. Compositions are indicated for blocks for stamping plain carbon steels, tough alloy steels, etc.; heat treatment is also considered. LFM (4b)

CRAFTSMANSHIP

CRAFTSMANSHIP is the product of skill, integrity and experience, nowhere more essential than in the production of fine forging steel. For nearly a half century, true Craftsmanship has guided the production of ASCO Special High Grade Forging Billets, this craftsmanship extending from the technicians who select and combine the raw materials; the workmen who labor at furnace and mill; the metallurgists who check the heat at every point; to the craftsmen who chip the billet to remove every trace of surface imperfection. This Craftsmanship is readily discernible in ASCO Special High Grade Forging Billets. It is your assurance that your finished forgings will be unfailingly adequate to the heaviest burdens industry can place upon them.

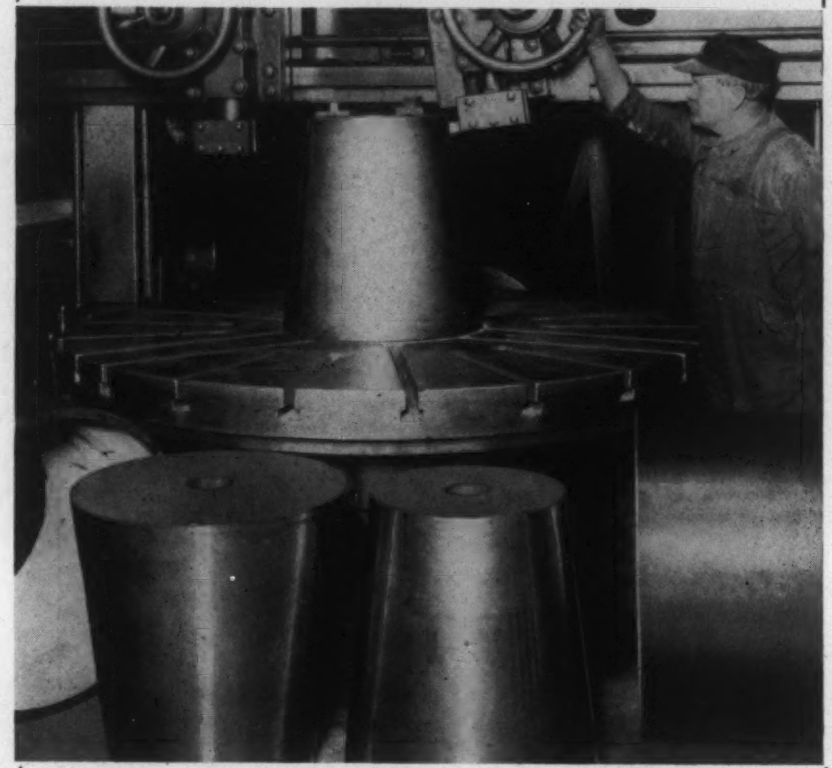
MODERNIZE WITH FIRTHITE
FOR
PROFITS



FIRTHITE sintered carbide has proved decidedly profitable for the machining of hard materials because it makes possible substantial increases in output and tool life—far beyond expectations.

For instance, manganese rolls, as shown above, could not be machined satisfactorily with high speed steel. Therefore, grinding was employed as a means of finish but the operation required from 27 to 40 hours per roll in addition to a comparatively high wheel cost. Now—with FIRTHITE these rolls are machined at an average of 7 hours each.

FIRTHITE has established itself as a superior cutting material for handling the average metal cutting operation as well as the unusual type of job, such as the manganese rolls illustrated, at a tremendously lower cost. FIRTHITE economies are the result of faster cutting and longer tool life.

When you are investigating modernization of your cutting tools for profits you will reach the same conclusion as that of hundreds of FIRTHITE users—that FIRTHITE is a cutting material offering savings far greater than any type of cutting material.

Our FIRTHITE engineering department invites correspondence relative to particular cutting problems and specific FIRTHITE sintered carbide uses.

Rubber and Wood Used for Dies in Forming Airplane Parts. Chas. O. Herb. *Machinery,* N. Y., Vol. 42, Mar. 1936, pages 425-430. To save the cost of expensive dies when only comparatively few pieces have to be made dies of wood or Zn faced with thin sheets of cold-rolled steels, and rubber pads in combination with Zn dies have been successfully applied; the process of making Zn dies from plaster of Paris pattern and their use is illustrated by examples. Ha (4c)

Metal Stamping in Small Lots on a Production Basis. *Mill & Factory,* Vol. 18, Mar. 1936, pages 65-66. The early days and present set-up of the A. Rogers Mfg. Co. plant at Dayton are described. Profitable production is based on use of temporary dies to establish correct tolerances for parts, thus avoiding corrections after permanent tooling, and excessive die charges. FPP (4c)

Flow of Metal in Stampings. Earl C. Booth. *Product Engineering,* Vol. 7, Mar. 1936, pages 90-92. Better materials for stamping and drawing processes are now available so that stamped and deep-drawn parts are widely used as their surface is cleaner and decorative finishes can often be applied directly. The initial design of a sheet to provide for the increased area to secure proper flow and avoid cracks is discussed and illustrated by a few practical examples. Ha (4c)

H. W. GRAHAM, SECTION EDITOR

Velocity of Machining and Choice of Tools (Vitesse d'Usinage et Choix des Outils) Wojcik. *Usine,* Vol. 45, Jan. 23, 1936, pages 35-37. Factors influencing speed and shape of tool dependent on type of metal to be machined and on material of the tool are discussed; tables of speed, feed and cutting angles for different materials are given. Ha (4d)

Machining Metals with a Gas Flame. Lipetzki. *Kachestvennaya Stal,* No. 9, 1935, pages 58-60. In Russian. Advantages obtained in rough machining using gas cutters are pointed out and the methods used are described. Data presented are taken from Linde Co. publications. (4d)

Tungsten Carbide and Cobalt Cutting Material. Arthur Haslam. *Metallurgia,* Vol. 13, Feb. 1936, page 103. Points out superiority of sintered W-C tools in machining several materials that tool steels cut with difficulty if at all. JLG (4d)

Tool Steel Industry Is Prepared to Meet the Challenge of New Developments in Machines. R. Edsom Emery. *Steel,* Vol. 98, Mar. 9, 1936, pages 55-56. Modern machine-tools have increased speed and power, greater accuracy, and ease of operation. Introduction of new cutting materials has made possible increase in power and speed. Varieties of tool-steels to meet various requirements have been increased considerably. Chemist and metallurgist have contributed an important part to perfection of present-day tool-steels. Continued research is needed, however. MS (4d)

Factors Influencing the Nature of the Cutting-Speed/Tool-Life Curve. O. W. Boston, W. W. Gilbert & C. E. Kraus. *Metal Treatment,* Vol. 1, Autumn 1935, pages 141-142. See "The Life of Turning Tools as Influenced by Shape," *Metals & Alloys,* Vol. 5, Nov. 1934, page MA 516. JCC (4d)

Machining a New Free-cutting Aluminum Alloy in Automatics. *Machinery,* N. Y., Vol. 42, Mar. 1936, pages 464-465. Al alloy 11S (described in *Machinery,* Aug. 1935, page 751) is best machined with the standard 18-4-1 high speed steel, or, when the cutting speed is not very high, as for drilling of small holes, ordinary C steels can be used. General information on lubricants and tool shapes are given. Ha (4d)

Broaching Facilitates Production of Dodge Connecting Rods. *Iron Age,* Vol. 137, Feb. 20, 1936, pages 42-43. Improved quality and an increase of 360 pr. of rods and caps/hr. has been achieved by the Dodge Bros. Corp., by installation of 5 vertical broaching machines. VSP (4d)

Tungsten Carbide, An Example of the Profits and Problems of Modernization. Edwin L. Cady. *Mill & Factory,* Vol. 17, Nov. 1935, pages 37-40. Describes application of W carbide equipment to a modernization program. After preliminary exploratory period W carbide has proved advantageous for cutting-tools, wire-drawing dies, electrical contact points, lathe center points, etc. with several hundred percent improvement in tool life or operation time often reported. Failures due to "abruptness" are described and methods of avoiding them mentioned. Lists for checking possible applications, performance and capital saving are included. FPP (4d)

The Torque and Thrust of Small Drills Operating in Various Metals. O. W. Boston & W. W. Gilbert. *Transactions American Society of Mechanical Engineers,* Vol. 58, Feb. 1936, pages 79-89. The results of a detailed study are recorded in which drilling with small drills from ⅛″ to ½″ diam. was done and the influence of speed, torque exerted and angle of helix was considered for 9 ferrous and nonferrous metals. The results are shown in curves. 13 references. Ha (4d)

A Five-Point Modernization Program Pays. Braun Gear Corp. *Mill & Factory,* Vol. 18, Mar. 1936, pages 56-58, 122-128. In order to use in gear manufacture the latest tool steels and alloys and the tough, refractory raw materials now available, and to provide in addition quicker deliveries, higher accuracy and lower costs, a continuous modernization method was evolved. Capital investment and rapidity of amortization of individual lathe, gear cutters, etc. are discussed in considerable detail. FPP (4d)

5. HEAT TREATMENT

O. E. HARDER, SECTION EDITOR

The Heat Treatment of Cast Iron. A. A. Timmins. *Proceedings Staffordshire Iron & Steel Institute,* Vol. 50, Session 1934/35, pages 121-128. The heat treating of cast Fe is, in some respects, similar to that of steel but the presence of Si, which causes instability of pearlite, will introduce modifications. Heat treatment is employed for cast Fe with the following objects in view: (1) The relief of casting stresses, (2) annealing to soften cast Fe, (3) heat treatment by quenching and tempering, (4) special heat treatments such as nitriding and shorterizing. GTM (5)

Working of Light Metal Alloys in the Electric Furnace (Verarbeitung der Leichtmetalllegierungen im elektrischen Ofen) Knoops. *Elektrowärme,* Vol. 6, Jan. 1936, pages 24-27. Curves are given which demonstrate the sensitiveness of Al and Mg alloys to temperature of heat treatment; each alloy has a certain best temperature which must be kept within ± 10° C. in order to obtain the best physical properties (Brinell hardness, tensile strength and elongation). Types of furnaces are described. Ha (5)

■ 5a. Annealing ■

Controlling the Rate of Heating. A. M. Steever & L. A. Lindberg. *Industrial Heating,* Vol. 3, Jan. 1936, pages 51-54. The importance of adjusting the proper rate of heating to the physical properties of the material to be heated is stressed and the bad effects of thermal lag in temperature measuring instruments are explained and methods of control to overcome discussed. Ha (5)

Application of Heat to Processing of Copper Alloys. R. S. Pratt. *Industrial Heating,* Vol. 3, Jan. 1936, pages 20-24. Heat treatment for hot working, homogenizing and annealing, necessity for temperature control and influence of the furnace type are discussed. Ha (5)

Various Applications of Oxy-Acetylene Flame (Les Applications Diverses de la Flamme Oxyacétylénique) *Revue de la Soudure Autogène,* Vol. 27, Dec. 1935, pages 4-9. Examples are given. FR (5)

Strain Annealing of Non-ferrous Metals. H. M. St. John. *Industrial Heating,* Vol. 3, Feb. 1936, pages 81-88. Season cracking is a defect peculiar to certain non-ferrous alloys when these have been worked into a wrought rather than a cast form. Causes, detection and means of overcoming it are discussed. This type of cracking occurs only when the metal is under strain; composition and shape of the metal are of great influence. A certain amount of intercrystalline corrosion must, however, be present for season cracking to occur. The mercurous nitrate test is the usual one to detect such cracks. Relief annealing at temperatures from 500° to 700° F. from ½ to 1 hr. is a cure for the defect. Ha (5a)

Bright-annealing Methods for Metals (Les Procédés de Recuit Clair des Métaux) L. Grangette. *Usine,* Vol. 45, Jan. 16, 1936, pages 29-31. Furnace types used in France are described. Ha (5a)

■ 5b. Hardening, Quenching & Drawing ■

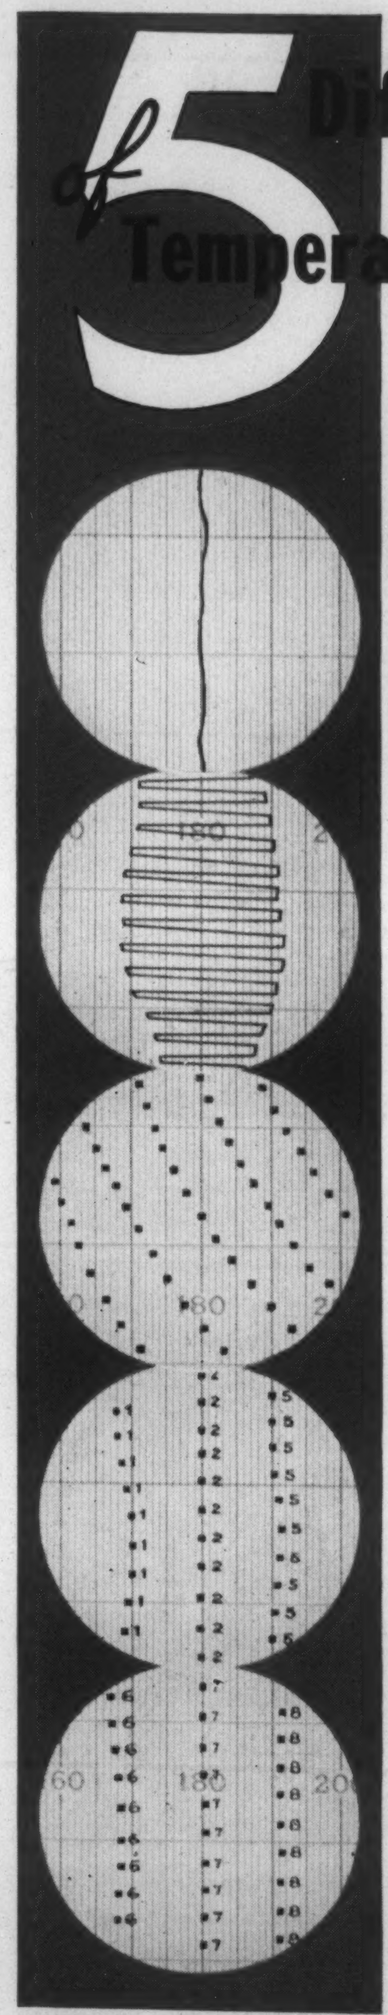
Heat Treatment of Aluminum Alloys. R. S. Archer. *Industrial Heating,* Vol. 3, Jan. 1936, pages 16-18; Feb. 1936, pages 90-94, 100. The theories about the hardening properties of Al alloys are explained, whereby 2 different hardening phenomena are recognized: (1) Pre-precipitation hardening which occurs on aging at room temperature after quenching from 1000° F., (2) precipitation hardening accompanied by actual formation of fine particles of the second constituent of the alloy which occurs on reheating for some hrs. at about 300° F. The properties of some Al alloys are given. The hardening effect of cold working can be removed by heating to 575°-675° F., very slow cooling is desirable. Solution heat treatment to bring the soluble constituents of the alloy into solid solution by rapid cooling to room temperature and precipitation heat treatment to produce further hardening after quenching are described. Ha (5b)

Heat Treatment of Cast Iron. J. E. Hurst. *Heat Treating & Forging,* Vol. 21, July 1935, pages 328, 337. Excerpt from presidential address before Institute of British Foundrymen. See "Surface Hardening Treatment Applied to Cast Iron," *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 58R/6. MS (5b)

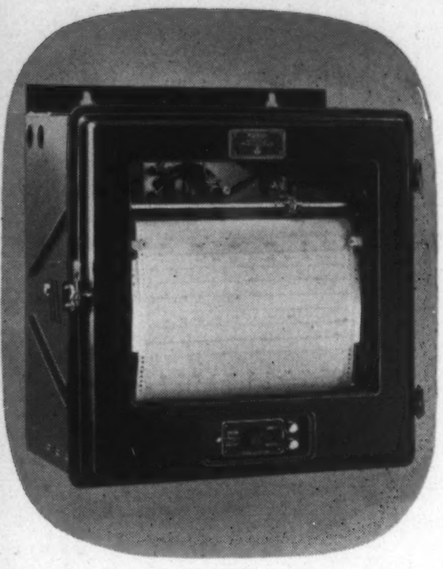
High Standards are Maintained in Heat Treating Springs. J. E. Coleman. *Industrial Gas,* Vol. 14, Dec. 1935, pages 7-8, 25. A modernized installation for heat treating and temperature control is described. Ha (5b)

Use of "Electric Eye" in Industrial Process Control. R. A. Powers. *Steel,* Vol. 98, Mar. 2, 1936, pages 40-43. Among applications described is one for controlling temperature in a resistance-type heater, used for hardening tips of valve stems. Heating current is turned on 0.1 sec. after dies have located work. About 0.75 sec. is required to bring valve stem from room temperature to 1700° F. At correct temperature, heating current is turned off, and 0.1 sec. later, valve is released and falls into quench tank. Another application is checking actual height of bouncing hammer in scleroscope when making hardness tests. MS (5b)

Shielding Thin Sections of Punch to Reduce Hardening Strains. W. T. Koehler. *Machinery,* N. Y., Vol. 42, Mar. 1936, page 467. A light sheet-Fe shield of 0.01″ thickness is placed over the sections to be protected in hardening processes. Ha (5b)



Different Kinds of Temperature Records



• Do you want to record one temperature; or eight different temperatures on the same chart? The new-series Foxboro Potentiometer Pyrometer offers you a choice of five different styles of record—from the continuous red line of a single-point machine to the six numerals in different colors or the eight numerals in one color.

This wide choice of records is but one of *scores* of improved features you'll find in the improved Foxboro Potentiometer. Others include the exclusive *compensating* slide-wire — integral mounting of slide-wire contact and pen carriage—rugged, yet super-sensitive galvanometer. All are fully explained and illustrated in new Bulletin 190-1. *Send for your copy.*

RELIABLE AIR SUPPLY

THE best man in your plant with the best oil or gas-fired equipment you can buy cannot produce a uniform and continuous volume of work without a reliable and adequate air supply. . . . . . Spencer Turbo-Compressors have met the exacting requirements of the metal industries for many years; primarily because of a simplicity in design that has resulted in extreme reliability.

A two bearing unit with wide clearances, light weight impellers, re-inforced heads and an extra-strong motor support construction, provides long life and quiet operation. Vibration is negligible and the air output is automatically maintained at a predetermined pressure, insuring uniform production conditions, day after day.

Spencer Turbos are now made in sizes down to ⅓ HP., which are easily mounted on the equipment they serve. Gas-tight and corrosion-resistant Turbos are also available. Ask your equipment manufacturer or write us for the bulletin.

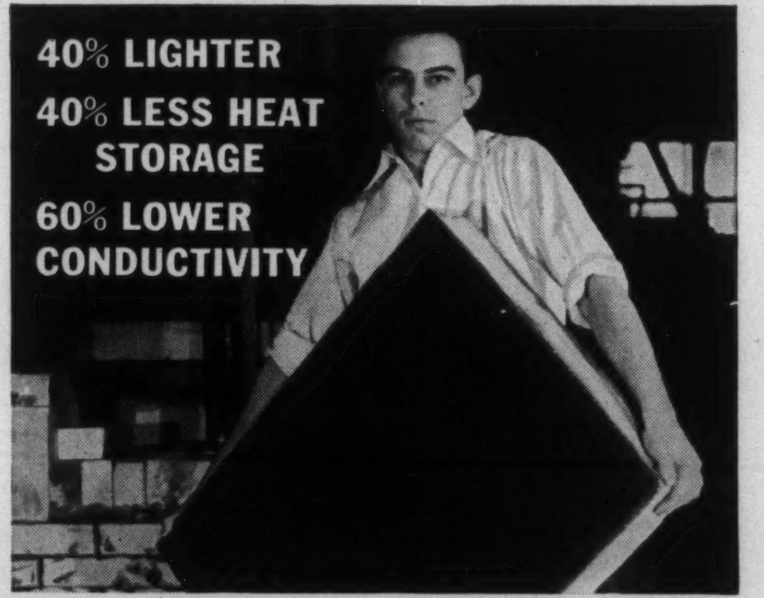
The Shorter-Double-Duo Process for Surface Hardening. *Engineering,* Vol. 141, Mar. 6, 1936, pages 273-274. **Local Surface Hardening.** *Machinery,* London, Vol. 47, Feb. 13, 1936, pages 601-604. Scope of this method has been extended and made applicable to pins and journals of crankshafts, rollers, and other parts of cylindrical form subjected to frictional wear. Describes procedure. The new development depends upon rapid application of heat, the rate of application being such that there is a limited accumulation of heat at outer surface sufficient to raise it slightly above Ac_3 critical point. Most crankshaft steels, provided they are straight hardening grades, may be treated by this new process. Gives analyses of suitable steels, and also results of tests. WB + VSP (5b)

Modern Developments in the Heat Treatment of Steel Rails. CECIL J. ALLEN. *Railway Gazette,* Vol. 64, Jan. 10, 1936, pages 56-63. The widely used Sandberg process for heat treating the heads of railroad and trolley car rails to produce the sorbitic structure is described. The process has recently been improved by increasing the water spray pressure during the first stage of the quench, instead of maintaining it constant. Actual treatment consists of the application of a "scotch mist" of water to the heated railhead, closely controlled as to time and pressure according to the shape and chemical composition of the railhead. Extensive tensile strength data show the uniformity of results obtained, and photomicrographs are included illustrating treated and untreated structures. The tensometer was used to measure exceptional yield stresses with highly satisfactory results. The comparatively low cost of the treatment in relation to the increased yield points and enhanced susceptibility to work-hardening, desirable for this application, are emphasized. FPP (5b)

Effect of the Wire Velocity in the Lead Quenching Process of Steel Wire on the Mechanical Properties of the Drawn Wire (Einfluss der Durchlaufgeschwindigkeit beim Bleipatentieren von Stahldraht auf die Festigkeitseigenschaften des gezogenen Drahtes) ANTON POMP & H. RUPPIK. *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Vol. 17, No. 23, 1935, pages 259-274. The quality of a steel is improved by the process known as "lead-patenting" whereby the wire is heated in a continuous furnace to the required temperature and quenched in a lead bath immediately on leaving the furnace. The improvement in quality depends on the temperature with which the wire enters the lead bath and on the temperature which it acquires in passing through the bath. A steel wire of 0.66% C was used to study the conditions for different temperatures and velocities. It was found that a change in velocity in the bath very strongly influences the dependence of the mechanical properties on quenching and bath temperature. Good properties were obtained with 950° C. quenching and 450° C. lead bath temperature which constitute the highest and lowest permissible temperatures. The highest velocity still giving good results was 5 m./min. with which fairly uniform values of mechanical properties at different temperatures were obtained. 960° C. quenching and 560° lead bath temperature gave a pronounced optimum of properties at all velocities. Microstructural photographs and test curves for all conditions in the experiment are reproduced. 14 references. Ha (5b)



JOHNS-MANVILLE JM PRODUCTS REFRACTORIES

40% LIGHTER
40% LESS HEAT STORAGE
60% LOWER CONDUCTIVITY

NEVER BEFORE a monolithic refractory like Light Weight Firecrete! It handles more easily; saves time and money in the casting of furnace doors, floors, special shapes. It stores less heat; intermittent furnaces come up to temperature faster; heat saved in cooling off. Low thermal conductivity cuts radiation losses. Full story in new brochure. Write Johns-Manville, 22 East 40th Street, New York City.

Intensity and Penetration of Hardness in Nickel-chromium Steels with Low Carbon Content (Intensita e Penetrazione di Tempere in Acciai al Nichel-Cromo a Debole Tenore in Carbonio) T. NATALE. *Industria Meccanica,* Vol. 18, Feb. 1936, pages 59-63. Curves were taken with 2 Ni-Cr steels containing only 0.15% C to find how deeply the hardening effect by quenching from different temperatures penetrates and what effect different temperatures of subsequent drawing has. At the same time, the velocity of cooling was determined and found to be the greater the higher the initial temperature. Cooling is at first fairly rapid and then slows down. Ha (5b)

Heat Treatment of Packard "120" Automobile Parts. J. B. NEALEY. *Industrial Heating,* Vol. 3, Mar. 1936, pages 173-174. Cyaniding baths and gas fired carburizing muffles, and the installations to treat small automobile parts with the least possible handling are described. Ha (5b)

Heat Treatment of Cast Iron. R. G. MCELWEE. *Transactions American Foundrymen's Association,* Vol. 6, Dec. 1935, pages 27-38. The author discusses the practical heat treatment of cast Fe from 3 angles, first for lowering hardness, second for increasing hardness, and third, controlling hardness by special irons. Under the second heading Fe of martensitic structure and its application for various types of castings are discussed. Under special irons the author uses as an example one containing approximately 2.5% C, 1.5% Si, and Mn 0.35%. This Fe is cast white and on heat treating produces a tensile strength of 90,000 lbs./in.^{2}, an elastic limit of 70,000 lbs./in.^{2}, with an elongation of approximately 4% and a hardness of 235 Brinell. M. H. MAWHINNEY, SECTION EDITOR

Improving Open-Hearth Furnace Design. WILLIAM C. BUELL, JR. *Steel*, Vol. 96, June 3, 1935, pages 56-58; June 10, 1935, pages 52-53, 55-56; June 17, 1935, pages 49-50, 52; June 24, 1935, pages 50, 52, 54; Vol. 97, July 1, 1935, pages 40-42, 44, 46; July 8, 1935, pages 50, 52-53; July 15, 1935, pages 57-58, 60-61; July 22, 1935, pages 45, 47-48; July 29, 1935, pages 40, 42-43, 44; Aug. 5, 1935, pages 58, 61-62; Aug. 12, 1935, pages 54-56; Aug. 19, 1935, pages 44, 46, 49-50, 52; Aug. 26, 1935, pages 45-46, 48, 50; Sept. 2, 1935, pages 63-64, 66-67; Sept. 9, 1935, pages 53-55; Sept. 16, 1935, pages 44-45, 47; Sept. 23, 1935, pages 81-82, 84, 86; Sept. 30, 1935, pages 38-42; Oct. 7, 1935, pages 53-54, 56, 58, 61; Oct. 14, 1935, pages 55-57; Oct. 21, 1935, pages 54-55, 57-58; Oct. 28, 1935, pages 46-48, 50; Nov. 4, 1935, pages 58, 60, 62; Nov. 11, 1935, pages 56-57, 60, 63-64; Nov. 18, 1935, pages 60, 63-64; Nov. 25, 1935, pages 47, 49, 52, 54-55; Dec. 2, 1935, pages 50-51, 53; Dec. 9, 1935, pages 38-40; Dec. 16, 1935, pages 53, 55-56; Dec. 23, 1935, pages 45-46, 48, 54. Continues series previously published in *Steel*, Vol. 91-93 (*Metals & Alloys*, Vol. 5, Apr. 1934, page MA 138). Detailed treatment of that part of the furnace below the charging floor. Describes details of typical installations, discusses principal factors to be considered in design and presents methods of designing system along more efficient lines. Shows importance of correct lay-out of auxiliary system collectively and of the several components individually. Considers structural design of steel and brick-work of slag-pockets, fantails, and regenerators. Pays much attention to economies of refractories and insulation. Describes methods of determining sizes of the various critical areas to effect optimum control of flow of the gases. Discusses features of single and multiple pass regenerators of both the vertical and horizontal types, checker-brick designs, method of laying brick, connecting flues, and heat transfer in the regenerators. Presents graphic methods of solving heat transfer problems and applies them to design of checker passes and flues. Treats of design and construction of butterfly, H_2O-sealed, and slide-valves; and construction, design, operation, and economics of waste-heat boilers. MS (6)

A Graphical Method of Calculating Heat Loss Through Furnace Walls. CLARENCE F. WEINLAND. *Journal American Ceramic Society*, Vol. 19, Mar. 1936, pages 74-80. Discussion of thermal conductivity data in form of true conductivity. Graphical solution of problems in equilibrium heat flow is shown and theoretical background is discussed in detail. A typical problem is solved by the new method. See also *Metals & Alloys*, Vol. 6, Sept. 1935, page MA 360R/9. WB (6)

Solid Reactions at 1000° to 1200° C. Between MgO or BeO and Ni, Fe, Cr, Mn and Their Oxides. LOUIS NAVIAS. *Journal American Ceramic Society*, Vol. 19, Jan. 1936, pages 1-7. Problem was initiated because of possibility of reaction of Ni-Cr resistance wire and Ni-Cr-Fe metal sheath in some types of tube furnaces with the MgO or BeO refractory packed between the sheath and resistance wire. Tests were made with oxide powders in contact with MgO and BeO and heated in dry air, dry N_2 and wet air and wet N_2. The reactivity of the oxides was determined by the coloration produced on the refractory; the order of reactivity being found to be Ni, Fe, Cr, Mn, the last being the most reactive oxide. Fe and Cr were about par for both MgO and BeO and Ni oxide showed no reaction with BeO. The BeO was less affected than MgO in all cases. The reaction of the metals with the refractories paralleled the behavior of the oxides, except that in oxidizing atmosphere the extent of the reaction, elementary metal-refractory oxide is greater than when the metallic oxides are in contact with refractory thus leading to the finding that the process of oxidation increased the rate of reaction of the underlying oxide with the refractory. Tests were made in H_2 at 1200° C. with metals and metal oxides, of the oxides Mn alone showed slight reaction, of the metals Cr and Mn alone showed slight reaction. Binary, 50-50, alloys of the individual metals and a ternary, Ni-Fe-Cr, alloy were also tested and showed less reaction than the single metals. Greater reactivity was found for wet air than for dry air. WB (6)

Developments in Chemical Apparatus. Electric Furnaces, Parts 5 and 6 (Fortschritte des chemischen Apparatewesens. Elektrische Oefen, Lieferungen 5 und 6) Edited by ADOLF BRÄUER & JOSEF REITSTÖTTER. Akademische Verlagsgesellschaft, Leipzig, 1936. Paper, 7½ x 11½ inches, Part 5, pages 177-192, 449-592, Part 6, pages 193-236, 593-656. Price each part 28 RM, whole volume, to subscribers, 132 RM.

These two parts complete vol. 1, completing the abstracts of German patents on electric furnaces through No. 540, 969, and through 1931.

There are two pagings, one for a general classification with references to the patent numbers concerned, the other for the patent abstracts themselves in numerical order.

The whole volume is a very complete and handy collection. The patents are so fully abstracted that, in patent searches to reveal the German art, much of the work could be done directly from this book. The specification is usually condensed, the claims given in full, one or more important figures reproduced and information given as to the number of illustrations shown in the original.

MISCO

BELT CONVEYORS

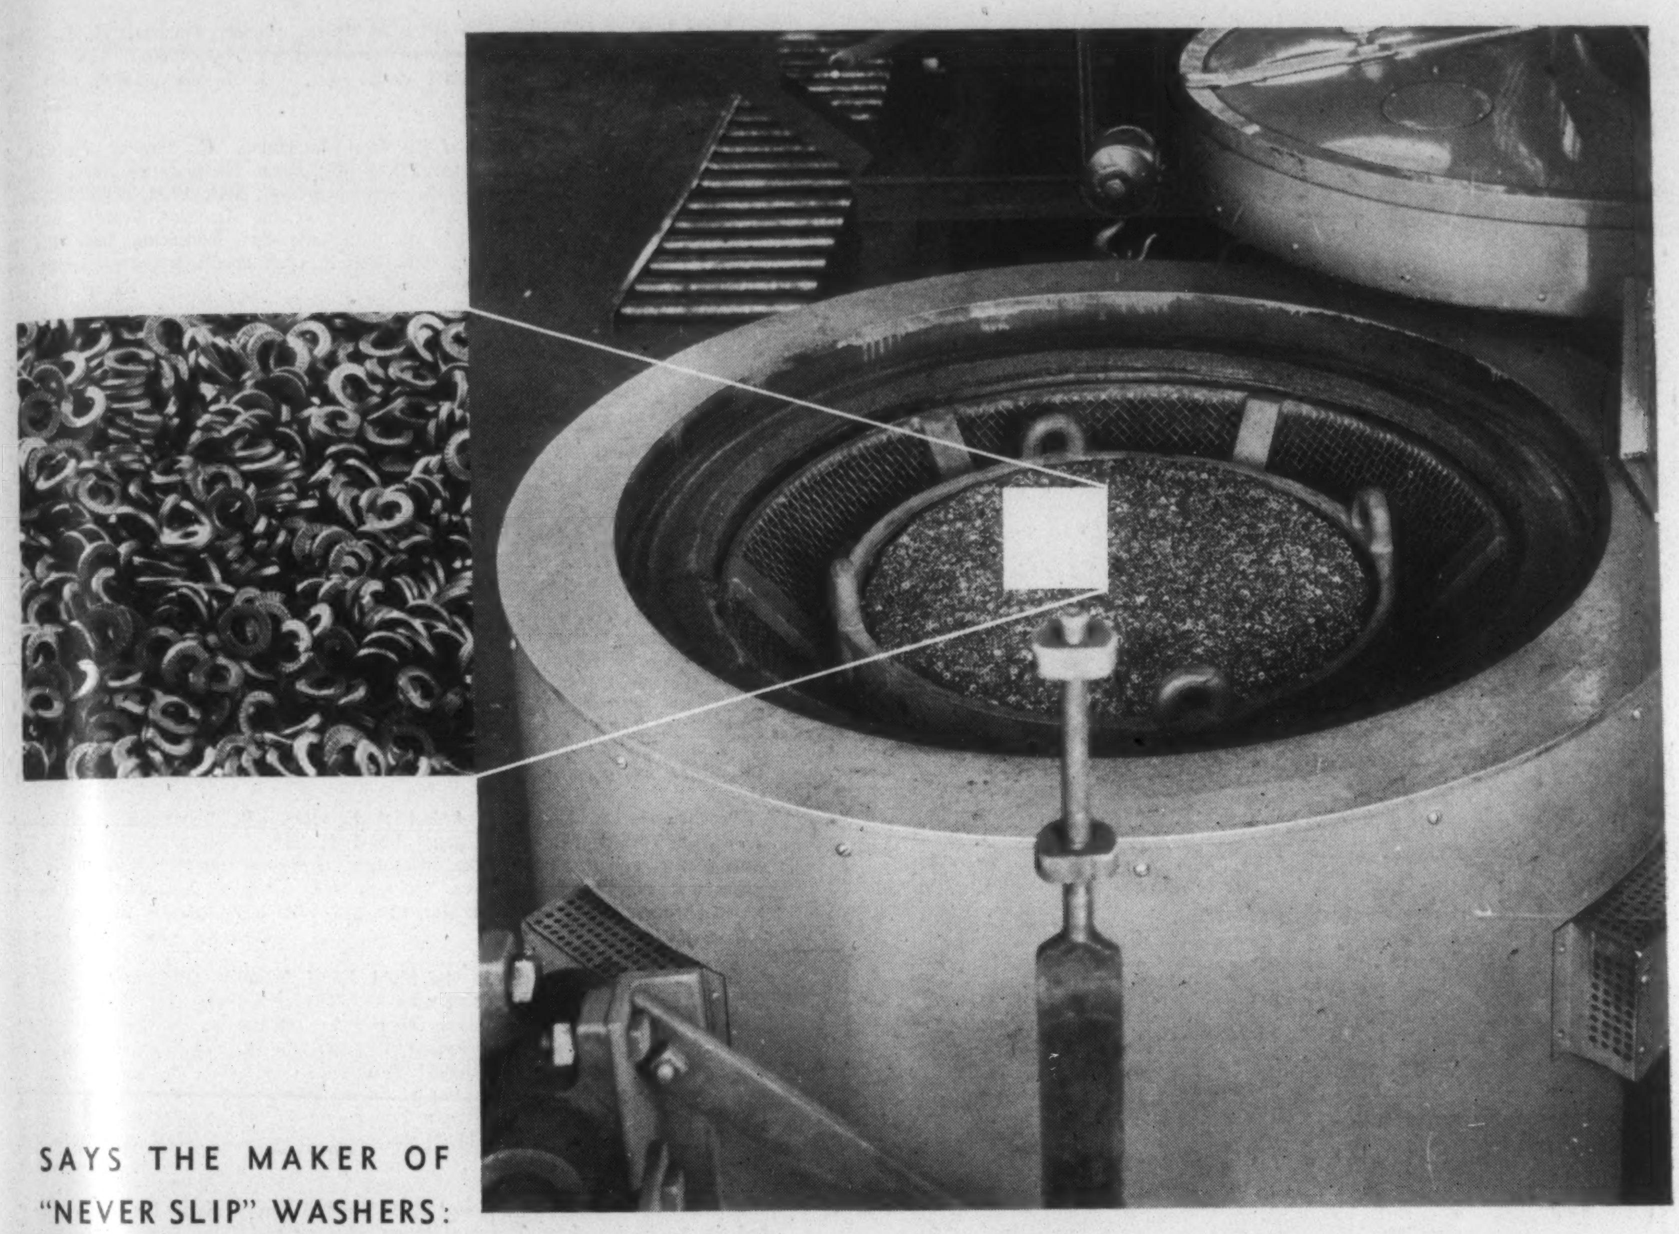
for use at high temperature

For many years the makers of Misco have specialized in the design and manufacture of chain and belt conveyors for use at high temperature. Thirty individual types and sizes are now available. Misco chains and belt conveyors are precision built to meet the exacting requirements of modern heat treating furnaces. Your inquiries are invited.

MICHIGAN STEEL CASTING COMPANY

One of the World's Pioneer Producers of Heat and Corrosion Alloy Castings

1981 GUOIN STREET, DETROIT, MICHIGAN



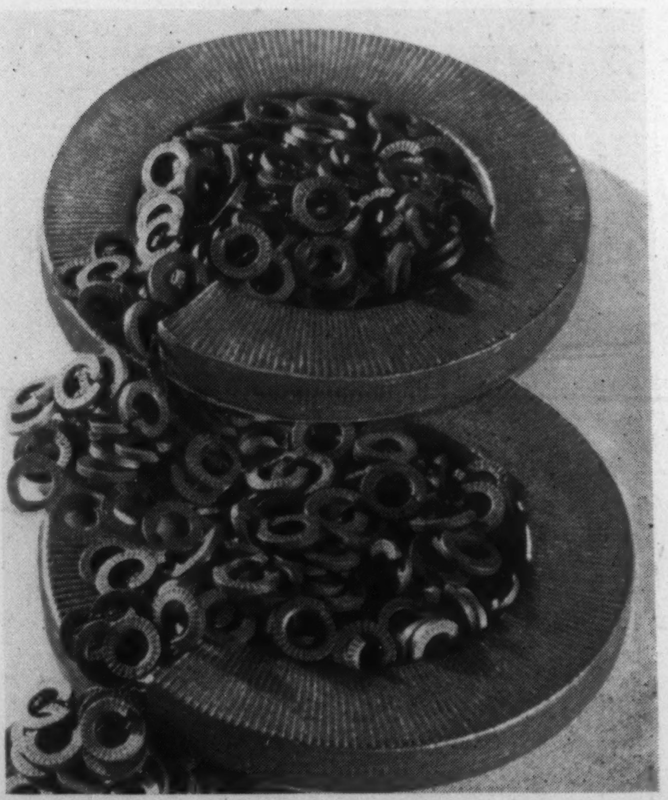
SAYS THE MAKER OF
"NEVER SLIP" WASHERS:

FOR BEST TEMPERING, GIVE US HOMO

Today the Philadelphia Steel & Wire Corporation tempers lock-washers to higher uniformity than ever before—and tempers at lower cost. They give credit to their new high-production, low-maintenance Homo Furnaces.

Uniformity of "physicals" is far inside the S.A.E. specs., even in the tiny sizes, which form extremely dense loads in the furnace. This uniformity is secured automatically, without relying on a skilled furnace operator. Homo forced-convection gives even heating under completely automatic control, and records all temperature facts about each heat. Cost is low; the Homo draws a tremendous volume—half a ton of washers to spring temper in forty minutes or less. Maintenance is low; this furnace has new-design heater, alloy top casting and guide rails.

If your product has small or medium-size parts that can profit by uniform, low-cost tempering, investigate the new Homo—It gives distinctly superior results.



Size of parts and density of load has very little effect on Homo capacity to temper uniformly and speedily. Washers ranging from ⅛" to 1½" in diameter go to the Philadelphia Steel & Wire Corporation's Homo equipment, and if still smaller or even larger sizes should be ordered, they would receive the same uniform Homo temper.

Refractory Problems in Basic Alloy Steel Production. G. Soler. *Industrial Heating*, Vol. 3, Mar. 1936, pages 189-192; *Blast Furnace & Steel Plant*, Vol. 24, Jan. 1936, page 106; Feb. 1936, page 186; Mar. 1936, pages 265-266. From paper read before Refractories Division of the American Ceramic Society. Factors determining the selection of refractories and influencing their life in steel plant service are discussed, conditions in open hearth furnaces, electric arc furnaces and ladle linings are considered.
Ha + MS (6)

Possibilities and Difficulties of Air and Gas Measurements by the Inoculation Process (Die Möglichkeiten und Schwierigkeiten der Luft- und Gasmengenmessung nach dem Impfverfahren) G. Neumann. *Archiv für das Eisenhüttenwesen*, Vol. 9, Oct. 1935, pages 179-183. The inoculation method although advantageous where other methods are uncertain still needs further development; the method is somewhat costly. It is quite precise, however, and is thus suitable for calibration though not for routine analysis.
Se (6)

Forging and Heat Treating Locomotive Parts. J. B. Nealey. *Steel*, Vol. 98, Mar. 23, 1936, pages 32-35. Describes shops of Pennsylvania Railroad at Altoona, Pa., with chief attention to furnaces. All furnaces are gas fired. Blacksmith shop 1 has 2 3-chamber forging furnaces, 2 2-chamber drop forge furnaces, and 7 single-chamber forging furnaces. Wrought-Fe scrap is reclaimed by blooming into billets, which are then drop forged into various parts. Blacksmith shop 2 has 6 drop-hammer furnaces, 18 smaller furnaces for swing-belt hammers and forging-machines, and 6 car-bottom and 4 cylindrical vertical furnaces for heat treating. Car-bottom furnaces are used for annealing prior to machining. Hardening is done in both the cylindrical, vertical and car-bottom types. Carburizing is carried out in 2 single-door, box-type furnaces. Boiler-shop has 2 large double-end furnaces for heating heavy plates.
MS (6)

Recuperation as Applied to Industrial Furnaces. B. Sampson. *Industrial Heating*, Vol. 3, Feb. 1936, pages 102-104; Mar. 1936, pages 161-164. The principles of recuperation and the advantages in economy due to preheating of gas and air in the combustion process are explained. Increased production and better working conditions around a furnace equipped with a recuperator described.
Ha (6)

Electric Melting Furnaces in the Light Metal Industry (Elektroschmelzöfen in der Leichtmetallindustrie) U. Schwedler. *Elektrowärme*, Vol. 6, Jan. 1936, pages 20-24. Most important types of electric furnaces for the melting of light metals are crucible, tank and induction furnaces. The particular advantages of each type with regard to the metallurgical behavior of the melt and the absorption of gases are discussed and the economy of an oil heated tank furnace, an electrically heated tank furnace, and an induction furnace for a daily capacity of 5 tons compared. The melting cost per ton of Al was found to be 37.60, 37.30 and 27.40 RM. respectively for these 3 types.
Ha (6)

A Discussion on the Report on "Waste Heat Boilers in Open Hearth Practice." Led by A. F. Webber. *Journal West of Scotland Iron & Steel Institute*, Vol. 48, Part 1, Oct. 1935, pages 3-12. The procedure and results of the Park Gate test are described. The construction and advantages of the Spanner thimble tube boiler and of the Sinuflo fire tube boiler are described. The use of a water tube boiler is compared to that of fire tube boilers. A properly designed economizer will lower the temperature 55° to 80° C. The results of the test are not representative of ideal conditions because the gas temperature and flow were less than the boiler was designed for and because the producer gas was not of the most desirable composition especially with respect to moisture content (38.7 grains/ft.^{3}). They are considered representative of what may be expected because frequently the amount and temperature of the gases is actually less than allowed for in the design.
FGN (6)

Automatic Combustion Control for Furnaces and Boilers Improved. E. W. Wagenseil. *Steel*, Vol. 98, Feb. 17, 1936, pages 54, 65. Automatic combustion control equipment available at present for metallurgical furnaces and boilers is far superior to that offered prior to depression. Installation of such equipment on existing furnaces and boilers would effect improvement in operation and reduction in costs.

Note on the Failure of a Gold Fuse in Contact with Nickel-chromium Alloy. M. C. Caplan. *Journal Institute of Metals,* Vol. 57, No. 2, 1935, pages 197-198. See *Metals & Alloys,* Vol. 6, Nov. 1935, page MA 451R/3. (6)

Forging at the Columbia Tool Steel Company. R. J. Jamison. *Heat Treating & Forging,* Vol. 22, Jan. 1936, pages 16-17. **Gas-Fired Forging Furnaces.** W. G. Gude. *Steel,* Vol. 98, Feb. 3, 1936, pages 48, 50. At the Chicago Heights plant, 4 furnaces were converted to gas firing. Insides were redesigned and rebricked. Each furnace is equipped with 3 low-pressure sealed-in burners of special design mounted in a specially constructed combustion chamber. Each furnace is equipped with 2-position gas and air mechanical positive proportioning valves. Controls include continuous gas analysis recorder for each furnace, highly accurate furnace pressure-gages, and gas pressure regulators. Crew foreman determines heating program for a given charge. By controlling furnace atmosphere, surface decarburization has been reduced 66⅔% and scaling, 75%. Use of relatively high positive furnace pressure assures uniformity of the product. Firing speed has been increased 500%. Danger of overheating or underheating work has been eliminated. Thermal efficiency of furnaces was increased about 50%. MS (6)

New Electric Furnaces in the Solingen Industry (Neue Elektroöfen in der Solinger Industrie) K. Mertens. *Elektrowärme,* Vol. 6, Mar. 1936, pages 102-103. Electric furnaces especially developed for the heat treatment of cutlery of alloy and rustless steels are described. Ha (6)

New Open-hearth Checker Increases Efficiency of Regenerator Chambers. M. K. Mellott. *Iron Age,* Vol. 137, Mar. 19, 1936, pages 44-45. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 125L/3. VSP (6)

Electric Furnaces. W. S. Gifford. *Iron & Coal Trades Review,* Vol. 132, Mar. 20, 1936, page 529; *Electrical Review,* Vol. 118, Mar. 20, 1936, page 423. A brief review is given of the spreading use of electric furnaces in British metallurgical industries. Normal frequency induction furnaces are used for production of brass; for melting small quantities of bronze and cast Fe the rocking arc and the rocking resistor furnace are employed, the latter having a graphite resistor rod. Surface hardening of crankshafts and similar parts was carried out by heating with a current of 2000 cycles and rapid quenching by water squirted through the hollow induction coils; the whole cycle takes only 45 sec. Ha + MS (6)

Electric Furnaces and Their Industrial Use (Les fours électriques et leurs emplois industriels) *Journal du Four Electrique,* Vol. 45, Feb. 1936, pages 58-59. General. JDG (6)

New Electric Induction Furnace (Nouveaux fours électriques à induction) *Journal du Four Electrique,* Vol. 45, Feb. 1936, page 57. Account of performance of a furnace developed by Halasz and Fekete using 100 volts 25 cycles current. The one ton furnace used for steel had an uncorrected power factor 0.50-0.60 and melted the charge in 90 min. with the power supply of 400 kw. hr. High frequency transformer or condenser batteries are not required. Structural details not given. JDG (6)

Open-Hearth Checker Increases Efficiency of Regenerator Chambers. *Blast Furnace & Steel Plant,* Vol. 24, Jan. 1936, pages 84-85. See "Designs New Checker for Regenerator Chambers," *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 125L/3. MS (6)

Metal Decorating Oven Built to Turn Out Exacting Work. *Steel,* Vol. 98, Feb. 24, 1936, pages 46, 48, 68. Describes conveyor oven, which is divided into several controlled zones, the number depending upon its length. Each zone has its own circulating fan, thermostatic control, and distributing duct work. Hood at loading zone prevents escape of volatile compounds and hot air into room. Cooling section is provided at end of hot zone. Source of heat is an air heater of either the direct or indirect type. Gas or oil-burners may be used. MS (6)

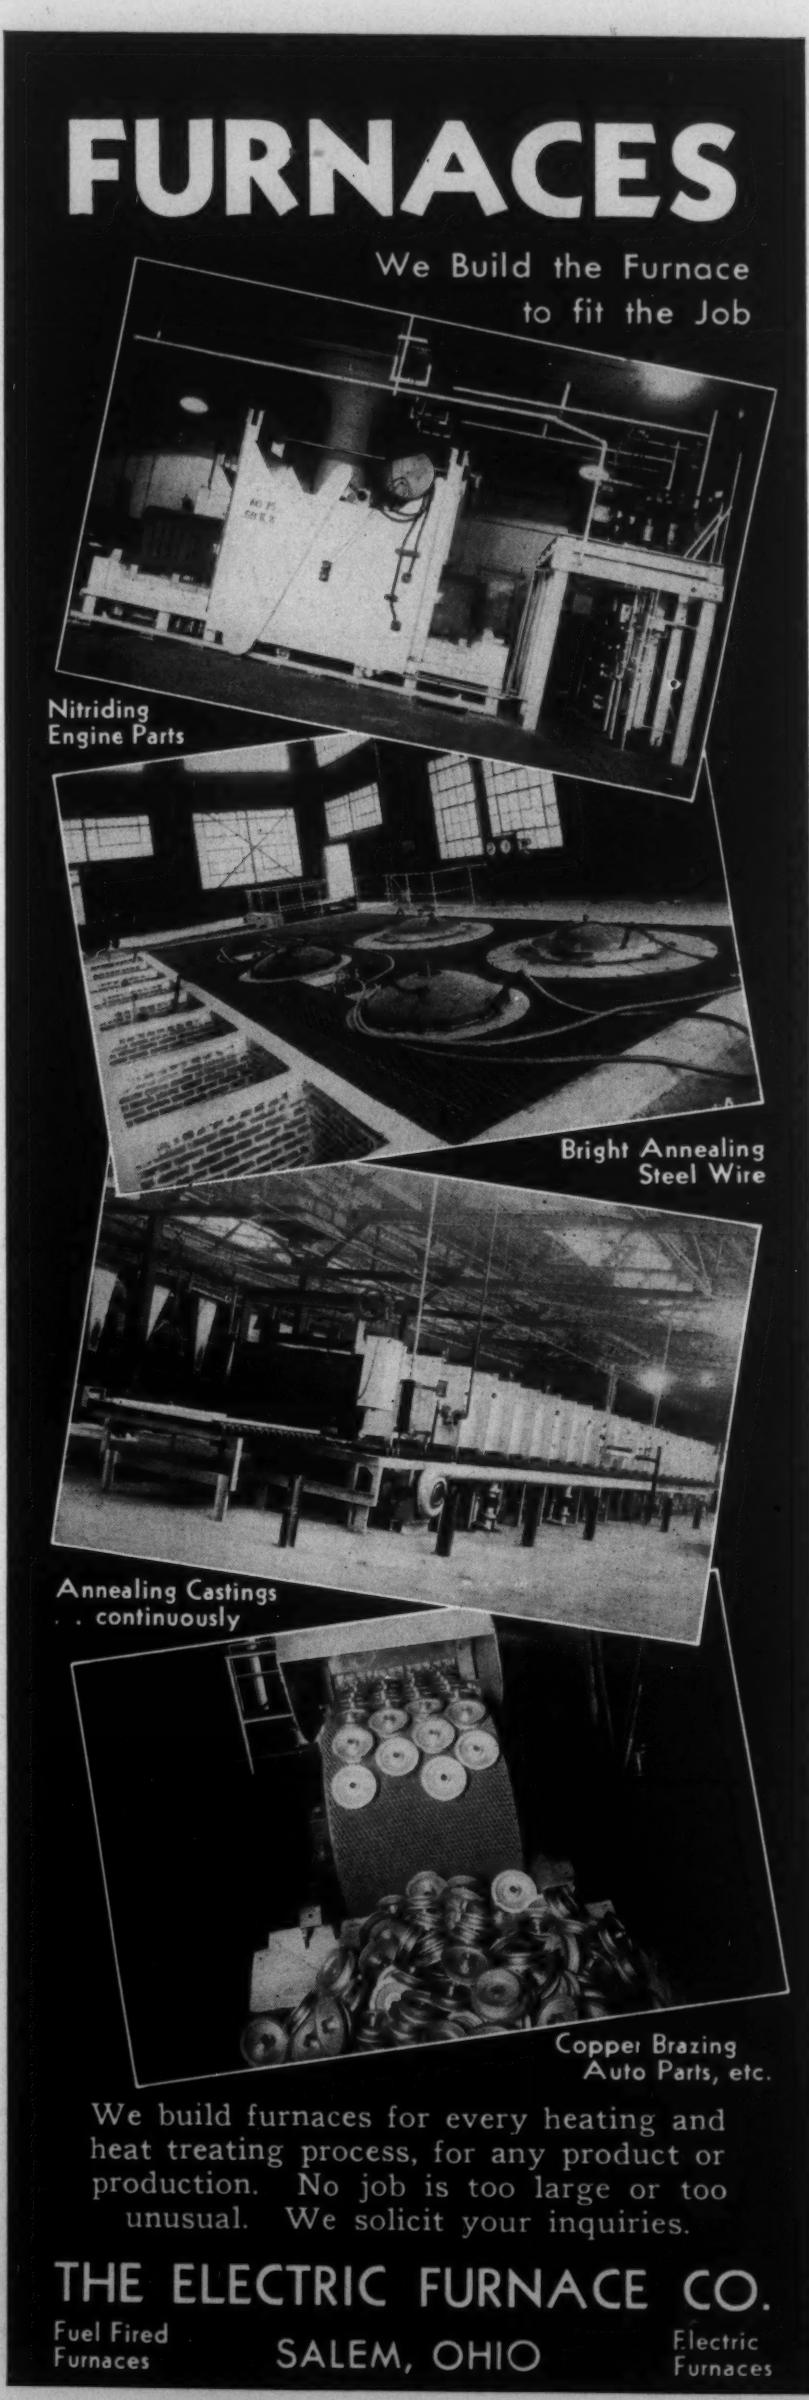
The Use of Penetrating Radiations in the Measurement of the Porosity of Refractory Brick. J. B. Austin. *Journal American Ceramic Society,* Vol. 19, Feb. 1936, pages 29-36. Measurements of X- and γ-ray absorption to determine porosity show the method is entirely practical. There is a slight advantage in use of γ radiation but in either case the method produces better results and more rapidly than present displacement tests. Theoretical discussion of factors involved and results reviewed in text, in tables and a few curves for various refractories. Description is given of the Failla vacuum-tube potentiometer with which the tests on porosity were made. WB (6)

Cupola Furnace Practice with Saar Coke (Aus der Kupolofen praxis mit Saarkoks) Karl Bäsel. *Giesserei,* Vol. 23, Feb. 14, 1936, pages 77-78. Coke from Saar coal which was considered unsuitable for use in cupola furnaces can be used if the blast is properly adjusted; section of nozzles to section of furnace should be 1:8 to 1:10. An advantage is its low S content and easy reaction. Best conditions of use are discussed. Ha (6)

A New Method for Studying the Flow Characteristics of Glasses and Slags at Elevated Temperatures. Elliott P. Barrett & James A. Taylor. *Journal American Ceramic Society,* Vol. 19, Feb. 1936, pages 39-44. Present methods of determining absolute values of viscosity and surface tension of glasses and slags are discussed and shown to be unnecessary in that relative values only are required. The new method is easily carried out and gives reproducible results which are relative values. WB (6)

Loading Device for Load-Test Furnace. John L. Carruthers. *Journal American Ceramic Society,* Vol. 17, Feb. 1936, pages 36-38. Discussion, description and detail-drawings of the new testing device to obtain high temperature load-carrying characteristics of refractory brick. WB (6)

The "Low-Down" on the Theories of Heating. *Industrial Heating,* Vol. 3, Jan. 1936, pages 11-15, 25. In a rather humorous manner the author approaches the problem of calculating heating processes, e.g. how long it will take to heat a bar, or the heat distribution within a bar at any time. Starting from the Fourier series a number of curves which can be used for practical purposes are developed without any higher mathematics. Ha (6)



FURNACES

We Build the Furnace
to fit the Job

Nitriding
Engine Parts

Bright Annealing
Steel Wire

Annealing Castings
. . continuously

Copper Brazing
Auto Parts, etc.

We build furnaces for every heating and heat treating process, for any product or production. No job is too large or too unusual. We solicit your inquiries.

Fuel Fired Furnaces

SALEM, OHIO

Electric Furnaces

Shamva Products

INCLUDE A FULL LINE OF

HIGH TEMPERATURE MULLITE CEMENTS

We are sometimes asked if the remarkable characteristics of "Shamva" Mullite bricks and shapes may be had in cements. They can. Here they are:

Mortar Cement (SM-40) — for gas-tight wall construction. Stubbornly resists the cutting action of flame and the penetration of corrosive and dust-laden gases. Equally good as a wash for super-refractories or as a bond for brick.

Dry Patching Cement (SM-50)—An air-setting cement which sets cold after application and forms a very strong bond. Excellent for small patching, coating walls old and new, or pointing up cracks. Especially effective in electric furnaces.

Plastic Patching Cement (SM-60) — Air-sets hard and does not shrink. Can be molded to any shape for cylindrical furnace interiors, furnace doors and monolithic structures. A perfect filler for holes in side walls and will replace entire sections of brick work.

Ramming Cement (SM-70)—For ramming furnace linings, special shapes or monolithic walls, with air hammer. Sets readily, does not shrink, gives long, satisfactory service.

MULLITE BOOK FREE

Describes the full line of "Shamva" Products and contains much valuable information of a general nature. Sent free on request.

Utilization of Coke-Oven Gas in Metallurgical Works (Die Verwertung des Koksofengases auf Hüttenwerken) W. EILENDER *et al. Stahl und Eisen,* Vol. 55, Oct. 31, 1935, pages 1153-1164. Report of a symposium on the general problems of the utilization of coke-oven gas in the iron and steel industry. SE (6)

Application of Gas-Fired Radiant Tubes to Porcelain Enameling. E. F. GEHRIG. *Iron Age,* Vol. 137, Feb. 6, 1936, pages 26-29. Describes the new method of heating of enameling furnaces by the Detroit Michigan Stove Co. The furnaces are heated by gas fired radiant tubes in a manner similar to the way electric heating elements are used. The conversion merely entailed the removal of furnace muffle and substitution of radiant tubes. VSP (6)

Results of Experiments with Cokes from Coal of Different Geological Origin in the Cupola Furnace (Versuchsergebnisse mit Koks aus Kohle verschiedener geologischer Herkunft im Giessereischachtofen) W. HOLLINDERBÄUMER. *Giesserei,* Vol. 23, Jan. 31, 1936, pages 73-77. The suitability of a certain kind of coke in a cupola depends principally on the construction and combustion process of the cupola. Foundry coke should have small pores, and the graphitization of the C in the coke should not exceed definite limits which, however, have not been definitely determined so far. Test results with several kinds of coke are given. Ha (6)

Heating, Quenching and Drawing Mechanized by New Furnace Unit. H. M. HEYN. *Industrial Gas,* Vol. 14, Feb. 1936, pages 13, 16, 24. A gas-fired furnace is described in which the 3 operations are combined with practical elimination of scaling. The furnace handles automatically 40 rear axle shafts (for automobiles) per hr. Ha (6)

Malleable Furnace Refractories. L. C. HEWITT. *Transactions American Foundrymen's Association,* Vol. 6, Dec. 1935, pages 51-54. A definite advance has been made in recent years in the development of refractories and their application in malleable furnaces. Bung brick have been improved particularly in respect to spalling action. Side wall life has been improved through the use of super fire clay brick and high temperature mortar. Tapout blocks of super fire clay type have also come into use. Fire brick bottoms laid with cold set high temperature cement are rapidly gaining in favor. CMS (6)

Fused Magnesia. BURROWS MOORE & W. L. PATRICK. *Industrial Chemist,* Vol. 11, Aug. 1935, pages 318-320. Review of some of the physical and chemical properties of electrically fused magnesia which is now being prepared on a commercial scale. RAW (6)

Steelworks Furnace Equipment. H. SOUTHERN. *Iron & Coal Trades Review,* Vol. 132, Jan. 17, 1936, pages 131-132. Trends of progress in design of ingot and billet reheating furnaces, continuous reheating furnaces, forging furnaces, furnace equipment and outlook are discussed. Ha (6)

Experiences in the Use of Refractories in the Steel Plant. LOUIS A. SMITH. *Industrial Heating,* Vol. 3, Jan. 1936, page 34. De-aired refractories have lately been made and appear to be very useful. Recent structural features in design of furnaces are discussed. Ha (6)

Some Uses of Refractory Materials in the Foundry. J. G. A. SKERL. *Proceedings Institute of British Foundrymen,* Vol. 26, 1932-1933, pages 566-592. See *Metals & Alloys,* Vol. 4, Sept. 1933, page MA 301; Dec. 1933, page MA 399. CEJ (6)

Electric Furnace in Continuous Manufacturing Operations (Der elektrische Ofen für Fliessbetrieb) G. SIMON. *Elektrowärme,* Vol. 6, Feb. 1936, pages 159-164. The advantages of the electric furnace, both of the batch and the continuous type, to fit in any place in series manufacturing operations are explained. It is especially profitable for quantity production, the continuous type being still more economical than the batch type electric furnace. Selection of furnace type, dimensions, and conveyors for the material are discussed, and examples of metallurgical and ceramic furnaces described. Ha (6)

Developments and Trends in Refractories. LOUIS J. TROSTEL. *Blast Furnace & Steel Plant,* Vol. 23, Sept. 1935, pages 621-622, 624-625, 632; Oct. 1935, pages 703-705, 720; Nov. 1935, pages 775-776; *Heat Treating & Forging,* Vol. 21, Aug. 1935, pages 391-393; *Iron Age,* Vol. 136, Nov. 21, 1935, pages 18-21, 90, 92, 94; Dec. 5, 1935, pages 26-29, 95. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 122L/4. MS + VSP (6)

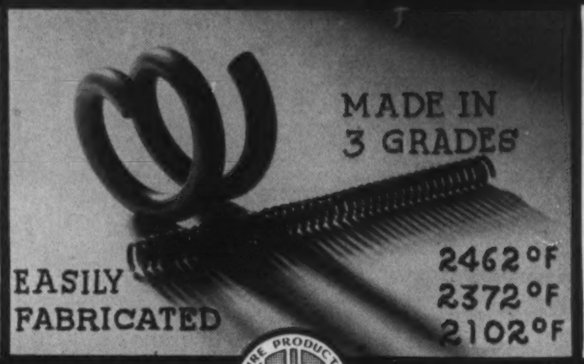
Everyday Applications of Insulating Firebrick. M. J. TERMAN. *Industrial Heating,* Vol. 3, Jan. 1936, pages 31-33; Feb. 1936, pages 121-124, 126. The advantages of insulating firebrick over heavy refractories in the metallurgical and ceramic industries as lining material are pointed out. They can be used up to 2950° F. except in places where mechanical abrasion and slagging conditions prevail. Tables of physical and mechanical properties are given, and a few installations with operating data described. Ha (6)

Cupola Refractories. *Foundry Trade Journal,* Vol. 53, Aug. 29, 1935, pages 145, 147. Discussion of paper on "Refractories for Foundry Use," by W. J. Rees (see *Foundry Trade Journal,* July 18, 1935, pages 47, 48; abstract in *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 62R/4). Jointing cements, blast-furnace linings, ground ganister, cases of over-insulation, refractory cements are discussed. With regard to the problem of C deposition, which occurred in the cooler parts of the cupola, and was sometimes noted in blast-furnace work, if by any oversight one used refractories in which there was a quantity of iron oxide, Turner said it was astonishing how much C could be deposited in those circumstances. A little globule of Fe was reduced and it continued to act upon CO so that more and more C was deposited until, if the process were allowed to proceed, the C became very much more bulky than the original brick on which it had been deposited. AIK (6)

DUCTILE KANTHAL LONGER LIFE

Here illustrated are two sections of Kanthal Wire coiled on mandrils and stretched when cold. It answers the query, "Is Kanthal ductile."

Send for sample and make your own test.



Kanthal D is indicated where greater resistance and longer life is desired than is available with nickel chromium alloys.

Kanthal A and A-1 have safe operating temperatures 300° to 400° higher than nickel chromium. Kanthal wire is drawn exclusively in the United States in our own Wire Mills at Southport, Conn.

THE C.O. JELLIFF MFG. CORP. SOUTHPORT, CONN.

Repairs to Linings of Steel Furnaces. *Engineering,* Vol. 141, Feb. 21, 1936, pages 216-217. Briefly describes a few repairs which can be made successfully while the open-hearth steel furnace is in operation. Door jambs can be repaired by moving the door sufficiently to one side while the old jamb is cut out. Loose bricks are put in to fill up the open space leaving just enough room to work on the jamb. The bricks are soaked in boiling tar to prevent chipping when they are exposed to the heat of the furnace. Dolomite which has been freed from fine powder and large lumps is used for repairing holes in a basic hearth. All metal must be completely removed before such repairing can be done. Roof patching can be done by laying bricks over the weak section which is satisfactory until the charge has been tapped and more permanent repairs made. Cavities in the back lining should be filled in with magnesite or chromium-ore powder. LFM (6)

Refractories for Smelting White Metals. EDMUND R. THEWS. *Metal Industry,* London, Vol. 47, Aug. 16, 1935, pages 154, 156. This article has been condensed and adapted to English conditions from a paper that appeared in *Tonindustrie Zeitung.* Fireclay bricks, containing 36-46% Al, are used in lining furnaces used for melting white metal and for recovery of residues. They are found to be more economical than basic bricks. The destruction of the hearth and leakage through the hearth or occasionally through the sides of the furnace are the major difficulties encountered in smelting these metals. Various methods of avoiding the weakness of joints, a common cause of low durability, are indicated. An efficient but expensive method of preventing leakage through the bridge is also outlined. HBG (6)

Deblanchal Rotary Melting Furnace. C. F. HERINGTON. *Blast Furnace & Steel Plant,* Vol. 24, Feb. 1936, pages 153-156. *Heat Treating & Forging,* Vol. 22, Feb. 1936, pages 93-96. Describes furnace for melting gray and malleable Fe, steel, non-ferrous metals, and alloys. Consists of cylindrical section made of heavy steel plate. Preheated air inlet, to which is attached the fuel burner, is provided at one end of furnace and is movable to 1 side to facilitate charging. Furnace rotates at a speed of 1 r.p.m. Combustion air is preheated to 500° F. in a recuperator having a slag chamber. Most industrial fuels of high calorific value may be used, fuel-oil being preferred. Furnace can be charged in 15-20 min. Time required to produce a melted charge, using preheated air and fuel-oil is about 70 min. Most satisfactory lining is a monolithic rammed lining. Pyrometers are provided for each end of furnace. This type of furnace is built in capacities of ½-12 tons. Comparison of costs of melting Fe using fuel-oil in Deblanchal furnace with tilting-type rotating furnace using pulverized coal, shows investment cost per ton of $0.32 and fuel cost per ton of $0.69 for former and $0.80 and $1.38 respectively for latter. Other advantages are simplicity in operation; low oxidation loss; wide range of products; high temperature of pouring Fe; adaptation of furnace to duplexing; freedom of metal from slag; accurate control of product; lower power consumption; and faster melting. MS (6)

The Slag Resistance of Steelworks Refractories. *Engineering,* Vol. 141, Jan. 31, 1936, page 134. From a paper read before the Refractory Materials Section of the Ceramic Society, London, Nov. 1935. LFM (6)

WHERE YOU CAN REDUCE YOUR COSTS!

Here is one method that is working successfully for many of our patrons, and thus increasing the profit margin—

Taylor Refractory Insulating Brick

by replacing two other refractory materials, is making a real saving in fuel consumption and operating time.

This light refractory is effecting appreciable savings in Lehrs,

Glass Pot Arches, Electric Furnaces, Soaking Pit Covers, Annealing Furnaces, Enameling Furnaces, Galvanizing Furnaces, Heat-Treating Furnaces, Core Ovens, Baking Ovens, Cyanide Furnaces, Boiler Furnaces, Lead Pot Furnaces, Forging Furnaces, Upsetting Furnaces and Waste Heat Boilers.

E. V. DAVID, SECTION EDITOR

Precautions for Welding in Unventilated Places. H. F. Reinhard. *Industry & Welding,* Vol. 8, Mar. 1936, pages 15-17, 25-28; *Steel,* Vol. 98, Mar. 2, 1936, pages 48, 50, 52. From paper presented before National Safety Council. Explosion dangers attending welding in badly ventilated rooms are explained and precautions to be used when welding gas tanks, etc. are discussed.
Ha + MS (7b)

Safe Rules Relative to Arc Welding (Prescriptions Relatives à la Soudure à l'Arc) *Revue de la Soudure Autogène,* Vol. 28, Jan. 1936, pages 10-11. Gives at length safe rules established by "Institut de Soudure Autogène" in connection with "Société des Ingénieurs Soudeurs." FR (7b)

Saw Welding. Owen C. Jones. *Industry & Welding,* Vol. 8, Mar. 1936, pages 21-25. Procedure in welding saws is described. Ha (7b)

Physical Properties and Structure of Gas Fusion Welds (Physikalische Eigenschaften und Gefügeausbildung bei Gasschmelzschweissungen) F. Leitner & Alfred Schmidt. *Autogene Metallbearbeitung,* Vol. 29, Feb. 1, 1936, pages 33-37. Experiments with specimens of pure welds, that is, specimens made of a V-weld in several layers, have proved that the physical properties of an autogenous weld are closely connected with the kind of structure formed in the weld. O and N exert only a minor effect in gas welds. A Mn-Ni alloyed welding rod gives better properties than an ordinary ingot Fe rod; it should be applied in high-stress welds where no stress-relief by annealing is used. Such annealing improves the notch-toughness in all cases. Annealing at 600° C. does not produce noticeable changes in the structure and notch-toughness of a gas weld. A subsequent heat treatment with the torch above Ac_3 after preceding cooling of the weld below Ac_1 brings about similar improvements in structure and notch-toughness as normalizing. The advantages of alloy welding rods are described and illustrated by photographs of structures. Ha (7b)

Pore-free Welding of Brass (Porenfreies Schweissen von Messing) Leemann. *Autogene Metallbearbeitung,* Vol. 29, Feb. 1, 1936, pages 37-39. The difficulties of obtaining a satisfactory weld in brass due to the large melting range (850°-950° C.) is explained. To obtain a pore-free welded joint a burner should be used as would be taken for the same thickness in Fe; the metal is first preheated with a neutral flame to a dark red, then the flame is adjusted to excess of O by reducing the acetylene supply, and quickly welded. Without sufficient preheat, pores and poor joints result. The same conditions prevail for bronze and red brass. To make the weld invisible (of same color as the base material) a welding rod of the latter should be used. Ha (7b)

Wire Mesh and Sheets Welded Without Fusion. A. Longoria & F. L. Spangler. *Welding Engineer,* Vol. 21, Mar. 1936, pages 26-28. A "new" process is said to "cause the molecules along the welded seam of two metallic sheets, closely butted together, to intermingle, provided the edges of the plate along the seam are first heated to a certain temperature." No further explanation is given, except that the author "eliminates the joint and makes both sheets as one piece by a shock."
Ha (7b)

The Micro Testing Machine Chevenard. *Welding Journal,* N. Y., Vol. 15, Mar. 1936, pages 11-13. Translation by Mathew Scioletich of article in *Soudeur Coupeur,* Vol. 10, Nov. 1935, pages 9-11. Diagrams of machine and various details are reproduced from the original, and mechanical properties curves are given progressively from parent metal through the weld. WB (7b)

Autogenous Cutting of Cast Iron (Das autogene Schneiden von Gusseisen) *Autogen-Schweisser,* Vol. 8, Aug. 1935, pages 91-92. Describes a new torch developed by the Office Central de l'Acétylène et de la Soudure Autogène in Paris for cutting cast Fe. The peculiar features of the torch and its manipulation are fully considered.
WH (7b)

Welding in British Railways (Mechanical Engineering) W. A. Stanier. *Welder,* Vol. 8, Dec. 1935, pages 778-782. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 129L/8.
Ha (7b)

Use the Emery Wheel Test for Your Unlabeled Welding Rods. J. B. Ames. *Welding Engineer,* Vol. 21, Mar. 1936, pages 30-31. It is explained how a spark test will reveal the nature of the steel and how to determine the suitability of a certain rod for a given work.
Ha (7b)

Maintenance Welding in Railroad Works. Frank A. Longo. *Welding Journal,* N. Y., Vol. 15, Mar. 1936, pages 20-25. Extensive discussion of practical problems involved in the maintenance repair of locomotive parts by flame and arc welding on the Southern Pacific. Building up wheel centers, brazing of Monel to brass valve seats for high strength, tough seat resistant to corrosion; arc bronze welding, hard surfacing, metal spraying, scrapping of equipment by flame cutting are reviewed.
WB (7b)

The Electric Arc Welding Process. T. A. Long. *Welder,* Vol. 8, Jan. 1936, pages 803-805, 818. Advantages of welded structures over riveted, bolted or cast structures are discussed, and the advantages of electric arc welding over gas or oxyacetylene welding explained. The overall working costs of the former process are said to be lower, the speed of welding higher and distortion effects not so evident as in gas welding. The electric arc process permits controlling with proper flux covered electrodes, the metallurgical analysis of the weld deposit. Characteristics of d-c. and a-c. welding are described and the structural differences illustrated by photographs of etchings.
Ha (7b)

Progress in Welding and Cutting in 1935. R. E. Miller. *Iron Age,* Vol. 137, Jan. 2, 1936, pages 496-497, 500-503, 506-507; Jan. 9, 1936, pages 24-29.. Considerable progress, both technical and commercial, has been accomplished the past year. Some of the developments discussed are: Oxy-acetylene cutting and welding; wider use of a.c. arc welding process; new electrodes and welding rods; electric resistance welding; and electric furnace brazing. VSP (7b)

Nitrogen in Metallic Arc Weld Metal. John W. Miller. *Welding Journal,* N. Y., Vol. 15, Feb. 1936, pages 5-10. Weld metal with 0.127% N was investigated with X-ray diffraction methods to determine composition and structure of nitride needles and are concluded to be probably made up of γ' phase of the Fe-N system and correspond to the compound Fe_4N. WB (7b)

The Welding of Wrought Iron. J. E. Fletcher. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 621-628. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 68R/4.
(7b)

Allocation of Electrodes to Various Types of Work. Jules Muller. *Welding Engineer,* Vol. 21, Jan. 1936, pages 30-32. Types of electrodes used, their comparative application and characteristics are described generally. Ha (7b)

ABC's of Welding Design. F. L. Plummer. *Industry & Welding,* Vol. 8, Jan. 1936, pages 20-22. The basic factors in designing good welds are discussed.

PROCEDURE HANDBOOK OF ARC WELDING DESIGN AND PRACTICE

DON'T GUESS—Mistakes Are Costly!

For Right Answers *SEE THIS BOOK* →

Procedure Handbook of Arc Welding Design and Practice . . . for Engineers, Designers and Welding Users
NEW THIRD EDITION contains 586 Pages . . . Over 700 Illustrations.

The New Third Edition answers all questions about arc welding. Most complete book of its kind available. Recognized everywhere as the authority on the art of electric welding. Used by prominent engineering schools and thousands of industrial plants in the United States and foreign countries. The new Handbook contains complete and accurate data on all latest arc welding applications and design procedures.

143 Pages of Important New Data added to Handbook. Everything necessary for most efficient use of arc welding is included in this book. Don't run a chance of costly mistakes or of not getting more profits when this gold mine of pertinent data is yours for such a small investment. **ORDER YOUR COPY NOW.**

ONLY $1.50 IN U.S.A.

Printed on fine paper with semi-flexible binding of simulated leather, gold embossed; size 6 x 9 inches.

The Handbook has saved thousands of dollars for others. It can do the same for you.

Inspection of Welded Seams in Pressure Vessels. Wm. D. Halsey. *Welding Journal,* N. Y., Vol. 15, Jan. 1936, pages 20-23. The difficulties involved in inspection of welded pressure vessels constructed in weld-pioneering era, prior to perfection of present welding are discussed and a new method of inspection is proposed. The method consists of cutting out circular disks which include the "antique" weld and a portion of the parent metal. The device for performing the operation is a circular milling cutter which has been improved since its appearance in Germany and Great Britain for weld inspection purposes. The improvement consists of an extended section on the cutter which allows retention of the disk cut out. This is important for pressure vessels because of impossibility of recovery of the disk if not retained. The disk is deep etched after cutting out and shows the macro of the weld thus allowing lack of fusion, dirtiness, etc., to be determined. It is proposed that where the weld macro passes inspection the hole formed in cutting the disk be tapped and provided with a plug. It is suggested that present qualification tests have gone too far in one direction (tensile strength and ductility tests) and not far enough in other directions such as requirement of welder test on actual material he will fabricate, whether plate, pipe, etc., and the X-ray examination of finish welded pieces constantly so as to give a continuous history of the soundness of the product the welder produces. It is argued that the present requalification tests at intervals of 6 months do not check on the welder except when he is on his best behavior. For unfired pressure vessels it is suggested that inspection of the weld with the cut-out-coupon method above would be more positive and less expensive than periodic requalification tests. The test holes may be closed by welding and it is suggested that the seam could be made intact thereby. WB (7b)

Welding in Aviation. Carl De Ganahl. *Welding Journal,* N. Y., Vol. 15, Mar. 1936, pages 8-9. The use of 1% Cr, ¼% Mo steel tubing is considered ideal for aircraft because of easy weldability and is reliable with proper welding technique. Heat treating of Cr Mo steel weld is standard procedure for safety. Oxyacetylene flame is used almost exclusively in aircraft due to extra care and training required for arc welding of thin sections. Spot welding abandoned because of the lack of toughness at the welds due to high rate of quenching of the Cr Mo steel and due to breakage of spot welds during heat treatment subsequent to welding. Corrosion of Cr Mo tubes is serious consideration and Cd coating is used for external protection, internally a film of boiled linseed oil is used by pouring the oil in through small hole at one end and draining, after which the holes are closed with metal screw. Aviation industry is now looking toward hard rolled, high tensile 18-8 steels for high strength (150,000 yield point) and good ductility (15-25%). The material is successfully spot and shot welded. The Cb or Ti stabilized 18-8 is standard for exhaust manifolds in Navy and Army Corps equipment. Weight strength ratio frequently favors use of 18-8 over other metals for the larger parts and higher stresses. WB (7b)

The Strengthening of Weak Bridges. C. S. Chettoe. *Structural Engineer,* Vol. 14, Feb. 1936, pages 62-84. The most satisfactory method of strengthening wrought Fe or steel girder bridges is by welding the weak, previously riveted flange angles and new supporting plates to structure. Cast Fe arches are best strengthened by encasement in reinforced concrete. FPP (7b)

Recent Progress in Realm of Aluminum and Aluminum Alloy Welding (Aperçu sur les récents progrès réalises dans le domaine de la soudure de l'aluminium et de ses alliages) Jacques Douchement. *Revue de Métallurgie,* Vol. 33, Mar. 1936, pages 189-196. Factors specifying welding conditions for light alloys are enumerated and the means for meeting them are presented. In fusion welding flux, filling rods and base metals must be considered. In resistance welding time and current concentration are important. JDG (7b)

Welding and Gas Cutting Industries in the United States of America (Aperçus sur l'Industrie de la Soudure et de l'Oxy-Coupage aux Etats-Unis) L. de Jessey. *Bulletin de la Société des Ingénieurs Soudeurs,* Vol. 6, Nov.-Dec. 1935, pages 1990-2005. Describes applications. FR (7b)

The Correct Repair of Gray Castings by Gas Fusion Welding with Cast Iron (Die richtige Ausbesserung von Grauguss durch Gasschmelzschweissen mit Gusseisen) H. Reininger. *Giesserei,* Vol. 23, Jan. 31, 1936, pages 52-57. The practical points to be observed in fusion welding of cast Fe are reviewed; this method can be used to make fully satisfactory repairs of any kind of defect in the casting provided proper pre-heating, welding temperatures and fluxes are observed. Suitable materials and procedures are described. 31 references. Ha (7b)

Welds Re-lace Rivets on Barges in Pittsburgh District. E. H. Sykes. *Welding Engineer,* Vol. 21, Mar. 1936, page 23. Advantages are briefly discussed. Ha (7b)

Electric Arc Welding of Stainless Steel. Geo. H. Sandberg. *Industry & Welding,* Vol. 8, Feb. 1936, pages 50-51, 64. Procedures used for different kinds of stainless steel are described. Ha (7b)

Welding, Soldering and Flame-cutting of Gray Iron (Schweissen, Löten und Brennschneiden von Grauguss) C. Stieler. *Giesserei,* Vol. 23, Mar. 13, 1936, pages 129-134. The different methods of welding of castings for repair purposes in the foundry are discussed and illustrated by examples. Flame-cutting can be done with the oxy-acetylene flame or electric arc by using special torches with heating nozzles. The metallurgical changes in the material near welds and cuts are explained. Ha (7b)

Welding of Inconel (La Soudure de l'Inconel) A. Boutté. *Revue de la Soudure Autogène,* Vol. 26, Jan. 1936, pages 8-9. Composition of Inconel is as follows: 80 Ni, 14 Cr and 6 Fe. (1) Oxy-acetylene welding: Owing to its high Cr content this alloy is to be classified, as to welding purpose, with stainless steels. Difficulties met with are the same as with the latter. Inconel can be welded using a special flux which is not to dissolve Cr oxide film but is to prevent formation of this film by giving a protective coating impervious to O_2 of atmosphere. Torch capacity must be between 50 and 75 liters of C_2H_2/hr. Strength of welds and corrosion resistance are about the same as that of base metal. (2) Arc welding: electrodes must be of Inconel coated with a special flux which allows maintaining a short arc. D.c. with reverse polarity is used. FR (7b)

MALLORY METAL ③

"Not Only Cut the Cost...
But Save Production Time"

"Since adopting Mallory #3 Spot Welding Tips, we have not only cut down the cost of the tips, but have saved considerable production time, because we eliminate the necessity of a lot of filing to maintain clean, well-shaped tips."

So writes one user of Mallory #3 Welding Tips. Before adopting Mallory Points, this manufacturer averaged about 100 assemblies per set of tips. Since adopting Mallory #3, the average has jumped to as high as 1,000 assemblies per set.

This is typical Mallory performance — and one reason why Mallory Leadership is so consistently maintained.

P. R. MALLORY & CO., Inc.

Cable Address—Pelmallo

Welded Steel Bridges in Victoria, Australia. W. T. B. McCormack. *Welder,* Vol. 7, Oct. 1935, pages 723-729. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 130L/10. Ha (7b)

Cutting Structural Steel. J. H. Zimmerman. *Welding Journal,* N. Y., Vol. 15, Feb. 1936, pages 21-25. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 129L/1. WB (7b)

Saw Welding. E. E. Olson. *Welding Journal,* N. Y., Vol. 15, Mar. 1936, pages 17-19. Attention is called to the highly specialized art of flame welding applied to repair of saws due to expert knowledge required of the effects of welding heat. Overheating of the high strength heat treated and worked metal of the saw is minimized by welding a small section and immediately forging the welded section gives fine grain. Backhand welding is recommended and other special considerations are reviewed. Welding of steel conveyor belting is best carried out by same procedure used for saw repairs. Bronze welding of saw teeth recess for building up of work material is reviewed. WB (7b)

Use of Welding Technique in Artcraft (Anwendung der Schweisstechnik in der Kunst- und Bauschlosserei) M. Roeder. *Autogene Metallbearbeitung,* Vol. 29, Mar. 1, 1936, pages 72-73. Examples of artistic effects in welding railings, gates, fences, etc. are described. Ha (7b)

The Welding of Aluminum. G. O. Hoglund. *Welding Engineer,* Vol. 21, Feb. 1936, pages 26-30. Review of processes applied in Al welding with examples; mechanical properties of wrought Al alloys are given. Ha (7b)

Welding in Railway Repair and Construction (Les Applications de la Soudure dans les Ateliers d'une Compagnie de Chemin de Fer) A. Heydacker. *Bulletin de la Société des Ingénieurs Soudeurs,* Vol. 6, Nov.-Dec. 1935, pages 1960-1978. Lecture before the French Welders' Society. Applications described deal chiefly with repair work. Following parts are studied: wheels, steel cross stay castings for locomotives, cast Fe cylinders, boilers. Possibility of using various welding processes for each part is discussed and illustrated. Last section describes all-welded tender. FR (7b)

Welding Alloy Steels in Aviation. C. de Ganahl. *Industry & Welding,* Vol. 8, Feb. 1936, pages 56-58. The particular problems in plane manufacture are discussed. Ha (7b)

Air-Powered Scoop, Arc-Welded, Digs, Carries and Dumps by Own Power. A. F. Davis. *Iron Age,* Vol. 137, Mar. 5, 1936, pages 36-38. Describes an air powered scoop which features arc welded seamless tubular construction. It was developed by Midwest Piping and Supply Co., Inc. Arc welding provides definite economies of construction in addition to greatest possible strength. VSP (7b)

Construction and Maintenance Problems Solved by Welding. A. F. Davis. *Welding Journal,* N. Y., Vol. 15, Jan. 1936, pages 2-5. A review in text and pictures of a variety of specific welding applications. WB (7b)

Arc Welding Used in Dredge Reconstruction. A. G. Bissell. *Welding Journal,* N. Y., Vol. 15, Mar. 1936, page 10. Descriptive plus photos. WB (7b)

Welding in the Fabrication of Large Reflecting Telescopes. A. E. Gibson *Iron Age,* Vol. 137, Feb. 6, 1936, pages 20-23. Deals with the construction of metal parts of a telescope, particularly those fabricated by welding. The work was done by Wellman Engineering Co. on a telescope for the University of Texas. High strength, rigidity and low weight are claimed for this form of fabrication. VSP (7b)

Welded Pressure Vessels (Récipient à Pression Soudés) H. Gerbeaux. *Revue de la Soudure Autogène,* Vol. 27, Dec. 1935, pages 9-10. It is necessary to reinforce a small radius pressure vessel around a cut circular opening. FR (7b)

Some Thoughts on the Development and Promotion of Arc Welding. LaMotte Grover. *Welding Engineer,* Vol. 21, Feb. 1936, pages 23-24. Wrong and right principles in present day welding practice are discussed; better and more rapid progress is foreseen when certain practices which are merely a tradition are abandoned for more scientifically and practically proven facts. Ha (7b)

Composition of Electrode Coatings. C. J. Holslag. *Welding Journal,* N. Y. Vol. 15, Feb. 1936, page 12. Brief, concise review of basic requirements of welding rod coatings and some of the many compounds used to effect desired arc and weld deposit character. WB (7b)

Oxy-Acetylene Welding and Cutting Progress. *Machinery,* N. Y. Vol. 42, Feb. 1936, pages 400-401. Present status. Ha (7b)

The Welding of the Alloy Steels. J. C. Hodge. *Welding Journal,* N. Y., Vol. 15, Jan. 1936, pages 6-14; *Iron Age,* Vol. 137, Jan. 30, 1936, pages 20-23, 81; Feb. 13, 1936, pages 52-56; *Canadian Machinery,* Vol. 47, Jan. 1936, pages 43-47. Discussion of the factors involved in the production of hard, martensitic transition zones next to the weld bead and the necessity for control or elimination of extreme hardness, and low toughness by means of preheat and after anneal or stress relief. General discussion of the suitability of various types of low alloy steels for particular applications where low alloy required less plate thickness and thinner plate allowed rapid construction by welding. WB + VSP (7b)

Electric Arc Welding and Its Applications. VII and VIII. M. Maurice Lebrun. *Welding Journal,* British, Vol. 32, Dec. 1935, pages 358-361; Vol. 33, Jan. 1936, pages 6-10. Brief discussion of d.c. arc welding generators, protective masks, glasses, welding and ground cables and electrode holders. Shows methods of suppressing overloads, connection of 2 welding units in series with one generator, and log of test of 3 phase transformer in a.c. welding. WB (7b)

Design and Construction of an All-Welded Multiple-Story Steel Structure. R. W. MacBride. *Structural Engineer,* Vol. 13, Dec. 1935, pages 458-466; discussion, Vol. 14, Feb. 1936, pages 99-101. Describes the design, assembly and erection of an all-welded steel-frame turbo blower power station, and stresses simplification of operations with welded construction as compared to riveted. Cost and weight of welded structure are less than riveted. Recommends selection and careful training of own welders, who become proficient in short time. FPP (7b)

Autogenous Welding of Copper (La Soudure autogène du Cuivre). L. Matteoli. *Cuivre et Laiton,* Vol. 9, Feb. 29, 1936, pages 79-81. The Cu deposited in the weld is extremely brittle, the tensile strength near the weld is not more than 15-16 kg./mm.^{2}, and the metal has the structure of cast Cu. The heat treatment to which the weld must be subjected to restore the good mechanical properties of Cu consists in heating and hammering, or, if the material is only very thin, hammering in cold state; hammering should be followed by annealing at 500°-600° C. Tensile strength is then 22-23 kg./mm.^{2} Steel and Cu can be welded together in the same manner as Cu to Cu, with a Cu welding rod. Arc welding does not give very satisfactory welds. Weld brazing of Cu is best done with a brass weld rod of 54-58% Cu, remainder Zn; the melting temperature of this composition is 880° C. Soldering with Ag and Sn is discussed, and also joining by hammering alone under heat is described although this method is not frequently employed. Ha (7b)

Hydraulic Manipulator of Welded Rolled Steel. J. D. Knox. *Steel,* Vol. 98, Mar. 9, 1936, pages 58, 61; *Blast Furnace & Steel Plant,* Vol. 24, Mar. 1936, pages 254-255. Blooming-mill manipulator is built of rolled plates and slabs of Cu-bearing 0.16-0.22% C steel. Thickness varied from 1½″ to 4″. Slabs up to 12″ thick were used where greater thickness was required. Base is heavier but movable parts are lighter than those of most manipulators. All plates were flame cut by machine to desired shape and contour. Various sections were joined by arc welding, 42,000 lb. of coated electrodes being used. Complete manipulator involved 1975 welded pieces. Every weld was peened and each complete part was stress relieved by holding it at 1100° F. for 4-5 hr. Questionable welds were drilled for inspection. All connecting-rods and links are of forged or welded steel. Pins and their bushings were case-hardened. About 40,000 lb. of bronze was used for bearings and at other points of friction. MS (7b)

Welding at the Ford River Rouge Plant. *Mill & Factory,* Vol. 18, Jan. 1936, pages 186-201. Practically all permanent stationary connections in the Ford cars and trucks are welded. The company's own oxygen plant supplies hundreds of welding machines performing over 5000 welding operations in the factory. The pressed steel division operates 600 completely automatic welding machines, including spot, arc, seam, flash, oxy-acetylene, etc. Gas tanks are now held in place by a traveling "Iron Man" while seams are being welded. All seam-welding operations are equipped with "thyratron" control; speed is 102″ in 1½ minutes, with 11 spots to the inch. A synchromatic timer controls the inner door-panel welding, which is performed, like a multiple-type punch press, with 40 spots simultaneously. The 3 panels of the rear body assembly are simultaneously welded, in a single "balloon" flash welding machine, along two 72″ seams in 7 seconds. 12 double-head, fully automatic arc welding machines weld the rear radius rod brackets to the tube, both sides at once, at a speed of 55″ a minute and current of 300 amperes, without a single skip. Oxy-acetylene welding is applied in many miscellaneous operations, especially at comparatively inaccessible points on the body. FPP (7b)

Permanency of Oxy-Acetylene Welding. F. C. Hutchinson. Presented at 36th Annual Convention, *International Acetylene Association,* Nov. 12-15, 1935, 9 pages. Available in mimeographed form from the offices of the Association, 30 East 42nd Street, New York, N. Y. Oxyacetylene pipe welds, made strong and tight by procedure control, remain so throughout the life of the pipe. Service and laboratory tests to determine corrosion resistance of oxyacetylene pipe welds have demonstrated that the welds can be counted on as at least equal to the pipe itself, regardless of whether corrosive attack comes from the inside or outside. Ability of oxyacetylene pipe welds to withstand terrific punishment without failure illustrated by severe treatment in construction of overland pipe lines, and by extraordinary tests imposed by hurricane, flood and earthquake. EVD (7b)

Little Known Facts Concerning the Repair of Bells. M. Ralph Horne. *Aluminium & the Non-Ferrous Review,* Vol. 1, Nov. 1935, pages 79-80. Refers just to the fact that bells which have cracked can be repaired by welding, taking care that the weld metal has the same composition as the bell. Instances of church bells so repaired are illustrated. JCC (7b)

The Welding of Low Alloy Steels. J. C. Holmberg. *Welding Journal,* British, Vol. 32, Oct. 1935, pages 306, 308; *Sheet Metal Industries,* Vol. 9, Nov. 1935, pages 715-716. From a paper before the American Welding Society. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 68R/9. WB + AWM (7b)

Composition of the Added Metal in Electric Arc Welds (Composizione del metallo di apporto nella saldatura elettrica ad arco) III. L. Losana & M. Jarach. *La Metallurgia Italiana,* Vol. 27, Oct. 1935, pages 703-706. The division of W, Mo, and V between slag and the added metal has been determined. The Fe-W alloy contained 74.86% W; the Fe-V alloy contained 52.46% V; the Fe-Mo alloy 48.70% Mo. In addition, there was some Mn, Si and C in each. W readily migrates from the electrode coatings to the weld, especially in the presence of Mn. Mo is little influenced by Mn, but C content increases with Mo content. V migrates readily with Mn present, while C increases greatly in the presence of V. AWC (7b)

Advantageous Use of Gas Fusion Welding in Machine and Boiler Design (Vorteilhafte Anwendung der Gasschmelzschweissung im Maschinen- und Kesselbau) K. Kohrs. *Autogene Metallbearbeitung,* Vol. 29, Jan. 1, 1936, pages 1-10. Examples illustrate the great savings which can be realized in cost of repairs when fusion welding is applied without reducing the mechanical properties of the welded parts. Ha (7b)

Casting and Welding (Giessen und Schweissen) Gustav Meyersberg. *Montanistische Rundschau,* Vol. 28, Jan. 16, 1936, pages 6-7. A general discussion of common practice in casting and welding metals and alloys. BHS (7b)

Autogenous Welding of Copper (La Soudure Autogene du Cuivre) L. Matteoli. *Cuivre et Laiton,* Vol. 9, Jan. 30, 1936, pages 31-35. Differences between autogenous welding of Fe and Cu because of their metallurgical and physical properties, preparation of the pieces, welding rods and welding procedure are discussed in general. Ha (7b)

Forge Welding with Water Gas. J. B. Nealy. *Heat Treating & Forging,* Vol. 22, Feb. 1936, pages 89-91. **Mechanized Forge Welding of Tanks.** *Steel,* Vol. 98, Feb. 10, 1936, pages 30-33. Describes equipment and practice of Columbiana Boiler Co., Columbiana, O. Natural-gas is used for welding. For certain products, this gas is converted to blue water-gas by proportioning with steam. Hammer welding machines are used in making longitudinal and circumferential seams of pressure vessels, except head seams which are made on roll and hammer welders. Hammer welder consists of a long steel mandrel on which anvil or bucker-up and lower forge ride back and forth. Below is a track on which rides carriage carrying vessel to be welded. Shell section is placed on carriage and run into welding position, and forges are placed on seam to be welded, one above and outside and other below and inside shell. Forges consist of steel cases filled with refractory brick with opening of approximately 5″ by 10″, into which gas burner fires. After sufficient length of time, forges are moved away and at same time, anvil and hammer slide and swing into position respectively and lap is welded. Only about 12″ of seam are heated and welded at a time and process is repeated until seam is completed. Sections then are welded together. Roller welder has an overhead steel platform with rails and carriage from which pneumatic hammer and hold-down devices are suspended. Just below is a steel roll and mandrel over which shell section rides and which serves as an anvil. Forges on long steel supports are just far enough below mandrel to straddle lower portion of shell wall. Rollers on arms inside section hold shell in position while it is rotated and welded. As each section is welded, it is annealed in a gas-fired pit-type furnace at 1650° F. After all circular seams are welded, vessel is annealed in a gas-fired ring-type furnace. MS (7b)

A Note on Some Results Concerning the Variation of Chemical Composition in the Gas-welding of Ordinary Steels. Albert M. Portevin & A. Leroy. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 2, pages 475-481. Reports analyses of gas welds of a number of C steels. See also *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 66R/1. JLG (7b)

Welding for the Steel Foundry Industry. V. G. Pearson. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 629-634. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 66L/2. (7b)

Welding in the Shipbuilding Industry. W. Strelow. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 385-390. General review with reference to German practice. See also *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 66R/10. JLG (7b)

Gas Welding Applied to Reconditioning of Bronze (Die autogene Auftragschweissung von Bronze) Benno Sixt. *Autogen-Schweisser,* Vol. 8, Oct. 1935, pages 109-113. 10 typical welding jobs on cast bronze objects are discussed and illustrated stressing the peculiarities and precautions to be borne in mind when welding bronze. WH (7b)

Repair of Charring Tanks for Charring Wood (Instandsetzung von Glühkesseln für Holzverkohlung) F. Stiehl. *Autogene Metallbearbeitung.* Vol. 29, Mar. 1, 1936, pages 75-76. Cracks in tanks of 1500-1800 mm. diam. and 3-4 m. length, 12 mm. thick were repaired; 100 mm. lengths at a time were welded and then hammered. The tanks must stand continuous heating to 800° C. and cooling, and the repaired cracks held well in service. Ha (7b) 1

Autogenous Welding for Assembling a Railing (Autogenschweissung bei Herstellung eines Treppengeländers) F. Stiehl. *Autogene Metallbearbeitung,* Vol. 29, Mar. 1, 1936, pages 74-75. Describes process. Ha (7b)

Welding in Marine Engineering. E. F. Spanner. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 591-597. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 128L/9. (7b) 2

The X-ray Examination of Welds. R. A. Stephen. *Sheet Metal Industries,* Vol. 9, Oct. 1935, pages 646-647. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 129L/8. AWM (7b)

Light Weight Rigid Welded Base on Kingsbury Drilling Machine. G. Donald Spackman. *Welding Journal,* N. Y., Vol. 15, Mar. 1936, pages 19-20. Details of base assembly by welding of plates which is estimated to have saved 33% of the weight of castings with the same strength. WB (7b)

3 **High Manganese Steel Welding.** E. W. P. Smith. *Industry & Welding,* Vol. 8, Feb. 1936, pages 59-62; Mar. 1936, pages 52-54. The particular uses of hard tough Mn steels are reviewed and means recommended for welding processes in resurfacing, repairing cracks, grinding. Ha (7b)

Difficult Repairs of Thick-walled Pieces (Schwierige Instandsetzungen an dickwandigen Werkstücken) J. Sehring. *Autogene Metallbearbeitung,* Vol. 29, Mar. 1, 1936, pages 65-68. A number of examples show how one should proceed when welding or repairing by welding thick pieces. Correct heating, no cold nor overheated spots, correct adjustment of the flame, and above all, conscientious welders are of first importance in carrying out difficult welding problems. Ha (7b) 4

Welded Pipe Structures for Fences (Geschweisste Rohrkonstruktionen als Einfriedigung) E. Schuch. *Autogene Metallbearbeitung,* Vol. 29, Mar. 1, 1936, pages 73-74. Descriptive. Ha (7b)

Residual Stresses, Distortion and Welding Procedure. H. W. Townsend & J. L. Adam. *Welding Journal,* British, Vol. 33, Jan. 1936, pages 16-17. Review of papers before Welding Symposium, Iron and Steel Institute 1935. WB (7b) 5

Physical-Chemical Phenomena of the Transfer of Metal During Welding. G. M. Tichodeev. *Welding Journal,* N. Y., Vol. 15, Mar. 1936, pages 26-31. 3 stages in arc welding process are considered; drop formation, expulsion of the drop to the work and solidification. 3 sources of heat for the first stage are kinetic energy of ions in cathode space, incandescent gases in cathode space and exothermic reactions in the fluid drop. Experiments were conducted with welding wire of varying C content keeping Mn and Si constant and other wires varying either Mn or Si while keeping the others constant. WB (7b) 6

The Phenomenon of the Erratic (Unstable) Welding Arc. G. M. Tichodeev. *Welding Journal,* N. Y., Vol. 15, Feb. 1936, pages 13-17. Cathode ray oscillographs of voltage and current of welding arc are shown for several compositions of welding rod. The stable arc is obtained when Si, SiO_2, Al, Al_2O_3 in the rod do not exceed limits given in the text. Stabilizing materials for arc are considered to be Fe oxides, CaO, MnO, FeS either in the rod or coating. Deoxidation with Al is considered to produce welding wire with poor welding quality due to erratic arc. WB (7b)

7 **Condenser Welding of Heating Resistors.** J. Wrana. *Electrical Review,* Vol. 117, Dec. 20, 1935, page 852. From *Elektrotechnische Zeitschrift,* Sept. 5, 1935. See "Welding of Wires of Nickel-chromium and High Heat Resisting Alloys by Condenser Discharge," *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 127R/5. MS (7b)

Electric Arc Repair of Rails. A. M. Wood. *Industry & Welding,* Vol. 8, Feb. 1936, pages 26-30. Procedure of building up worn rail ends and equipment is described. Ha (7b)

8 **Tests to Determine the Feasibility of Welding the Steel Frames of Buildings for Complete Continuity.** W. M. Wilson. *Welding Journal,* N. Y., Vol. 15, Jan. 1936, pages 28-38. Mechanical-civil engineering considerations. WB (7b)

The Various Types of Electric Butt-welding Machines (Die verschiedenen Arten elektrischer Stumpfschweissmaschinen) H. Wilbert. *Siemens-Zeitschrift,* Vol. 16, Feb. 1936, pages 41-46. Manually operated, semi-automatic and full-automatic machines are described and the selection of a proper type discussed as depending on section to be welded, kind of material, shape of workpiece and seam. Ha (7b) 9

Welding on Display at the Chemical Show. Orn T. Weirs. *Welding Engineer,* Vol. 21, Feb. 1936, pages 32-36; Mar. 1936, pages 34-38. Advantages of welded structures over other constructions are discussed and many examples of the oil, chemical, food and other industries illustrated. Ha (7b)

Welding of Vokar. N. M. Zarubin. *Redkie Metallui,* Vol. 4, Sept.-Oct. 1935, pages 48-51. In Russian. "Vokar," a mixture of W and C, was welded on to bar iron containing 0.05% C. The weld was examined micrographically and found to contain only WC and a solid solution of WC in Fe. No W_2C was found. HWR (7b) 10

British Railway Welding Practice as Applied to Bridge and Structural Repair Work. II. H. G. Ellson & J. Miller. *Welder,* Vol. 8, Jan. 1936, pages 819-823. Methods of repairing and reinforcing are described and illustrated by examples. Ha (7b)

Alloy Steels

Immediate Stock Shipment

The newer, finer, money saving alloy steels are immediately available from Ryerson stocks. All major S.A.E. specifications, Tool Steels, Stainless and Heat Resisting Steels are carried in a full range of sizes. All other steel and allied products—the most complete stocks in the country are also carried to meet your requirements. Whether you need a few pounds or a carload, your order will have our personal attention and will be shipped at once.

Write for the Ryerson Stock List—
Key to Immediate Steel.

Joseph T. Ryerson & Son, Inc., Chicago, Milwaukee, St. Louis, Cincinnati, Detroit, Cleveland, Buffalo, Philadelphia, Jersey City, Boston.

RYERSON

The Metallurgy of "Pure" Iron Welds. Gilbert E. Doan & William C Schulte. *Metals Technology,* Feb. 1936, *American Institute Mining & Metallurgical Engineers Technical Publication* No. 694, 16 pages. Welds were made with carbonyl Fe, H-purified carbonyl Fe, and steel in purified A and in air. In the purified A a crater did not form and no penetration resulted. Substantial removal of solid elements takes place on welding in A as well as on welding in air. Oxidation therefore does not seem entirely responsible for this removal in ordinary welding. The gas content of both Fe and steel was high in welds made in air. A coating was only partly effective in excluding these gases. Fe welds made in A are sound provided the A is of high purity, but a very little O in the A or steel causes porosity. Porosity in steel welds made in A is attributed to evolution of CO. Coated Fe welds made in air showed normal penetration and porosity was present. Fe welds in A have a coarse grain, while the same welds made in air were fine grained. Grain size seemed to correlate with N and O content. Microstructures are as would be expected from composition. Fe welds made in A were of low strength and plastic, elongation being 90% in tensile test. Fe welds made in air had a high strength with low ductility. Welds with coated rods had intermediate properties. Air has less effect on properties of steel welds than it does on Fe welds. Fe welds made in A do not age harden, but welds made in air do. JLG (7b)

The Manufacture of Welding Electrodes. C. H. Davis. *Mechanical World & Engineering Record,* Vol. 98, Nov. 15, 1935, pages 472-474. Paper presented to the Institution of Chemical Engineers. Coils of wire are cleaned, straightened and cut. Contact projections are then stamped on the wire and the coating extruded over it. WH (7b)

Resistance Welding. I. Theory and Application. L. H. Frost. *Welding Engineer,* Vol. 21, Jan. 1936, pages 44-47. Brief discussion of principles of the various welding processes and equipment used. Ha (7b)

Cast Welding Fittings for Pipe Lines (Gegossene Schweissfittings für den Rohrleitungsbau) Ernst Greger. *Der Autogen-Schweisser,* Vol. 8, Sept. 1935, pages 100-104. Advantages, commercial designs, joining and testing of pipe fittings joined by gas welding are discussed at length. The old-type screwed fittings are critically compared with the novel welded cast fittings. WH (7b)

A. C. Production Arc Welding. I. O. A. Tilton & J. T. Phillips. *Industry & Welding,* Vol. 8, Jan. 1936, pages 15-18, 30. The advantages of a.c. for welding with coated electrodes are due to the improved quality of the weld and the practical absence of the magnetic blow. Operating conditions are explained and welding transformer operating data given in curves. Ha (7b)

Underframes of 70-Ton Gondola Cars Welded Without Altering Basic Design. John E. Tesseyman. *Steel,* Vol. 98, Feb. 24, 1936, pages 60-61. Fabrication of underframe by arc welding instead of by riveting provides greater rigidity of structure and reduction in weight. Parts are assembled on a surface bed which serves also as a jig to hold them in place while they are tack welded. For finish welding, assembly is suspended by trunions and is turned, as required, to facilitate welding operations. MS (7b)

8. FINISHING

H. S. RAWDON, SECTION EDITOR

Reviewing Some Current Methods for Treatment of Metal Surfaces. *Steel,* Vol. 98, Mar. 2, 1936, pages 54, 57. Describes briefly (a) electrolytic cleaning of ferrous metals in solutions of Na_3PO_4 or Na_2CO_3; (b) electrolytic scale removal in acid and alkaline baths with simultaneous deposition of Pb or Sn; (c) electrolytic cleaning and pickling by making article first, the cathode in a 2-20% H_2SO_4 bath, and then the anode in a 25-75% H_2SO_4 bath; (d) forming a corrosion-resistant surface by electrolysis in a $Zn_3(PO_4)_2$ bath; and (e) forming a surface even more corrosion resistant by immersing Zn or Cd plated parts in a $Zn_3(PO_4)_2$ solution. MS (8)

Metal Finishing Advances in 1935. HERBERT R. SIMONDS. *Iron Age,* Vol. 137, Jan. 2, 1936, pages 553-554, 556-560; Jan. 9, 1936, pages 44-47. Discusses the practical applications of laboratory developments during the past year. They are: Al coating of steel, bright Ni plating, chemical black coating; plating on plastics; and improved enamels and lacquers. Includes comments from many authorities in various branches of metal finishing industry. VSP (8)

The Structure of Metallic Coatings, Films, and Surfaces. Introductory Paper and Concluding Remarks. CECIL H. DESCH. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1045-1048, 1288-1290. The importance of the symposium held by the Faraday Society on the structure of metallic coatings, films and surfaces is stressed and a summary of the papers presented is given. PRK (8)

■ 8a. Pickling ■

Conveyors Applied to Strip Mill Pickling Operations. J. H. HOUGH. *Iron Age,* Vol. 137, Feb. 20, 1936, pages 34-36. Describes method of continuous pickling and equipment used. VSP (8a)

Inhibitors. KENNETH B. LEWIS. *Wire & Wire Products,* Vol. 11, Mar. 1936, pages 127-129, 155. The action and types of inhibitors in wire drawing are discussed together with experimental study of the qualities of an inhibitor. It was found that an inhibitor acts differently on the various metallographic constituents of a steel; two general classes can be distinguished: low C basic steel rod and spheroidized steel, and patented rod, high C strip and medium C rod as rolled. An inhibitor satisfactory for one class is, in general, not satisfactory for the other, a mixture of both proved entirely unsatisfactory. Ha (8a)

Descaling of Metals. C. G. FINK & T. H. WILBER. *Chemical Trade Journal & Chemical Engineer,* Vol. 95, Oct. 12, 1934, pages 255-256. See "The Bullard-Dunn Electrochemical Metal Descaling Process," *Metals & Alloys,* Vol. 6, Oct. 1935, page MA 404L/8. MS (8a)

■ 8b. Cleaning including Sand Blasting ■

Stripping Costs on Damaged Parts Reduced by Electrolytic Process. *Steel,* Vol. 98, Mar. 23, 1936, page 49. Lacquer and enamel coatings can be stripped satisfactorily from metal articles by an electrolytic process. Parts are in an alkaline bath for 5 min., the parts being negative for 10 sec., then positive for 10 sec. and alternately negative and positive for entire period. In some cases, different periods for anodic and cathodic treatments may be required. Bath contains 13.6 oz. NaOH, 6.38 oz. Na_3PO_4, and 1.62 oz. Na_2SiO_3 per gal. H_2O. Equipment required consists of a d.c. generator of 6-12 volts, a steel tank, and where required, a conveyor. Between 30 to 50 amps./ft.^{2} may be used. Temperature of bath should be 200°-205° F. Operation is followed by a H_2O rinse. Method gives excellent results as to cleanliness. MS (8b)

■ 8c. Polishing & Grinding ■

Finishing Aluminum with Abrasives. H. K. WORK. *Abrasive Industry,* Vol. 17, Feb. 1936, pages 8-11, 23. Differences in polishing technique for Al from that for other metals are discussed. Wheels are softer and finer abrasive used. Procedure is briefly sketched and typical polishing operations for various Al products detailed. When castings which have been repaired by welding are finally to be given Alumilite finish, the welded areas are blended by polishing after annealing. Production of high luster and coloring of Al product are discussed. WB (8c)

Surface Grinding of Hardened Steels. W. DE V. HUNT. *Heat Treating & Forging,* Vol. 22, Feb. 1936, pages 79-83; Mar. 1936, pages 133-138. Paper read before the Steel Treatment Society of Australia. Summarizes history of grinding and grinding wheels and describes briefly manufacture of artificial abrasives; and selection of grinding-wheels. Recommendations for abrasives and vehicles for lapping various materials are given together with tests to obtain information about grinding and hardening cracks. MS (8c)

Low Cost Polishing. FRED B. JACOBS. *Mill & Factory,* Vol. 18, Mar. 1936, pages 62-64, 128-131. By using polishing methods for exposed metal parts of electric vacuum cleaners as examples, the author emphasizes attention which must be paid to setting-up wheels with glue and abrasive, type of glue, size of grit, drying time, wheel balance, etc. Automatic polishing is not convenient with the parts in question. Al alloy parts are polished dry with No. 120 Turkish emery on canvas wheels, oiled on felt or sheepskin wheels, cut down with tripoli, cleaned in organic solution, and color-buffed on previously worn-down wheels, without subsequent plating. Steel tubing is polished with a "skate" before being electroplated with Ni and Cr. FPP (8c)

Roll Grinding. J. R. LEONARD. *Wire & Wire Products,* Vol. 11, Mar. 1936, pages 125-126, 149-152. The problems occurring in the manufacture of highly polished rolls for wire and sheet rolling are discussed, the grinding process, coolants and lubricants, and grinding machines described. Ha (8c)

Grinding and Polishing of Iron and Metals (Das Schliefen und Polieren von Eisen und Metallen) KOCH. *Oberflächentechnik,* Vol. 13, Mar. 17, 1936, pages 63-64. Grinding, honing and polishing processes and machinery for these operations, speeds applied, and treatment of plated pieces are reviewed. Ha (8c)

Grinding Cobalt Wire to a Diameter of One-half Millimeter. O. S. MARSHALL. *Machinery,* N. Y., Vol. 42, Mar. 1936, page 466. Describes the procedure in making the wire from a 3/32″ square Co bar of 1½″ length. Ha (8c)

Abrasives and Grinding at the Ford River Rouge Plant. *Mill & Factory,* Vol. 18, Jan. 1936, pages 318-342. Grinding operations at the Ford plant are characterized by the variety of sizes, costs and types of wheels and by the dependence of the company on the technical cooperation of the abrasive manufacturers. The only accurate guides to grinding wheel quality are performance data, furnished at this plant by detailed comparative studies of wheels proposed for a specific operation. Factors considered are total number of pieces ground per wheel, hours of service, number of dressings, average production rate, average production per dressing, average approximate cost per part. Detailed description is given of grinding operations on the camshaft and the crankshaft. Extreme hardness and toughness of the cast alloy steel crankshaft necessitate 24″ to 42″ diameter grinding wheels for most semifinishing and all finishing operations. The grinding of cast alloy pistons, piston pins, valve seats and rear axles is described and the use of other miscellaneous grinding equipment is outlined. FPP (8c)

Barrel Burnishing. W. R. MEYER. *Monthly Review of the American Electroplaters' Society,* Vol. 22, Dec. 1935, pages 36-39. Extended abstract of "Das Polieren in Trommeln," F. Schwarz, *Oberflächentechnik,* Vol. 12, No. 20, 1935, pages 243-247. Barrel burnishing consists, first in an abrading action in which minute projections are worn off with some plastic flow, followed by a pressure homogenization of the surface in which the higher parts are worked into the depressions with a more or less mirror-like surface resulting. Both actions are accompanied by etching which keeps the metal free from oxide. A burnished surface consists of a severely cold-worked surface layer with a very fine crystalline structure. Such layers have greater resistance to chemical action than unburnished metal. Barrel burnishing may be done (1) dry, (2) wet, with soap solutions, (3) with steel balls, usually in the wet way, (4) scouring, with acids and an abrading agent like sand. Under (1) dry leather scrap with additions of Vienna lime, alumina, or rouge, at a barrel speed of 20-40 r.p.m. is used to burnish Ni or Cu plated articles and also Al and Zn. Under (2), wet burnishing without balls, only certain classes of work can be handled. Cavities will not be burnished. Wooden barrels at 30-50 r.p.m. are used. Some of the solutions are: for Al, acid K or Na fluoride .7, Igepon or Nekal .13, Na bisulphate .5 ozs/gal. For Fe and steel, soap flakes 5, soda ash 2.5, NaCN .7 ozs/gal. For Cu and Cu alloys, soap powder 4, soda ash 3, NaCN .13 ozs/gal. Under (3) steel balls, slugs, and jacks are used, dry or wet. If wet, same solutions as above. Condition of the steel balls is important factor. Best balls are highly polished hardened Cr steel. Barrel speeds 20-40 r.p.m. Under (4) sharp sand plus 1-5% solution of H_2SO_4. Time required may be from about 10 hrs. for brass and bronze up to 60 hrs. for materials like cast Fe. GBH (8c)

■ 8d. Electroplating ■

Chemical and Physical Properties of Electrolytically-deposited Metals in Relation to Their Structure. M. SCHLÖTTER. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1177-1181. Discussion page 1218. The chemical and physical properties of electrolytically produced metals can be changed by allowing anions to enter the crystal lattice. A relation was established between size of crystallites and overvoltage, both being dependent on the nature of the anions. A higher voltage corresponds to a larger anion. The higher overvoltage is also associated with higher concentration of H in the metal. Cu and Ag deposited from iodide solutions contain appreciable quantities of I_2 which results in an expanded lattice; the expansion increases with rise in the I_2 content. As the I_2 content in Ag deposits increases, the color changes from white to golden yellow. Ag containing intermediate quantities of I_2 does not blacken at all when treated with H_2S. In addition to the anions, the metal contains H_2. PRK (8d)

Ductility and Adhesion of Nickel Deposits. F. P. ROMANOFF. *Monthly Review, American Electroplaters' Society,* Apr. 1935, pages 8-20. See *Metals & Alloys,* Vol. 6, June 1935, page MA 238L/1. GBH (8d)

Influence of Bath Temperature on Chromium Hardness. R. J. Piersol. *Metal Cleaning & Finishing,* Vol. 7, Apr. 1935, pages 169-172. With a solution containing 250 g./l. CrO_3 and 2.5 g./l. H_2SO_4 increasing bath temperature (60°-160° F.) was accompanied by decreasing hardness of the deposit. The hardness fell gradually from 70° to 100° F. and was lowest and practically constant from 100°-140° F. with a current density of 1 amp./in.^{2} At a current density of 2 amps./in.^{2} the hardness increased from 80° to 120° F. then decreased from 120° to 140° F. The deposit at 120° F. was 20 times as hard as that formed at 125° F. GBH (8d)

Replenishing the Metal Content of Cyanide Baths. Nathaniel Hall. *Platers' Guide,* Vol. 32, Feb. 1936, pages 17-18. Free CN is one of the determining factors in the maintenance of a good throwing power and NaCN or KCN must be added with the metal salt to keep it at its optimum value. A table shows the weights of NaCN (96-98%) to dissolve 1 lb. of metal salt. WHB (8d)

Separation of Zinc in Alternating Current Electrolysis (Separazione di zinco metallico nella elettrolisi con corrents alternata) V. Montoro. *La Metallurgia Italiana,* Vol. 27, Nov. 1935, pages 761-765. A deposit of Zn is obtained on both electrodes from a solution of 1 *N* $ZnSO_4$, by the passage of an a.c. (50 cycles) varying from 0.3 to 6 amps./dm.^{2} The total deposit on both electrodes is about 1% of the theoretical value (assuming d.c. used), about ⅔ depositing on the cathode, and ⅓ on the anode. The electrodes used were pure Zn. The deposit is crystalline without any preferential orientation. AWC (8d)

Electrodeposition of Tin Alloys from Alkaline Stannate Baths. R. G. Monk & H. J. T. Ellingham. *Transactions Faraday Society,* Vol. 31, Oct. 1935, pages 1460-1468. Satisfactory electrodeposits of SnNi alloys, containing Ni up to about 25%, were obtained with high current efficiencies from an alkaline solution containing 90 to 100 g. of Sn as Na stannate, 2 g. of Ni as K nickelocyanide and 5 g. KCN/l., with Ni anodes, and operated at 70-75° C. Deposits containing 18-25% Ni obtained at about 0.15-0.5 amps./dm.^{2} were bright until the thickness exceeded 0.0005", thicker deposits were mat. Their hardness is about 7 times that of electrodeposited Sn. Deposits of higher Ni content are very brittle. From baths containing 89 g. of Sn as Na stannate, 2 g. of Sb as Na thioantimonate/l., and with a free alkali concentration of about 0.1 *N*, operated at 70-75° C., with Ni anodes, deposits containing from 6.5 to 82.3% Sb were obtained with current density varying from 9.1 to 0.1 amps./dm.^{2} Only the alloys containing less than 50% Sb could be obtained as satisfactory deposits of thickness as great as 0.0005". The deposits are very brittle and, though harder than Sn, their resistance to wear is low. PRK (8d)

Optimum Metal Concentration of Nickel Solutions. D. A. Cotton. *Monthly Review American Electroplaters' Society,* Vol. 22, Dec. 1935, pages 6-31. Solutions containing, respectively, 2, 4, 6, 8, 10, and 12 oz./gal. of Ni, (as $NiSO_4$) were studied. These solutions were otherwise the same, i.e. contained 3 oz./gal. of $NiCl_2$ and 4 oz./gal. of boric acid. Measurements were made on each solution at 80° F. and at 120° F. at several current densities of (a) anode and cathode efficiencies, (b) anode and cathode polarization, (c) total voltage across cell, and (d) throwing power with the following results:

C.d. Range	2 oz.	4 oz.	6 oz.	8 oz.	10 oz.	12 oz.
Cold (Amps./ft.^{2})	8-13	10-25	15-40	15-40	15-50	15-45
Hot	10-20	15-30	20-65	15-80	15-90	15-90
Voltage range						
Cold (Volts)	3-4.5	3-6	3-7	3-7	3-8	3-7
Hot	3-5	3-5	3-8.5	3-9	2-9	2-9
Average cathode efficiency	99.5%	98.8%	98.6%	99.4%	99.3%	99.5%
Average anode efficiency	99.9%	99.0%	99.3%	99.5%	98.5%	99.7%
Average throwing power	31 %	25 %	30.7%	31.6%	30.5%	29.6%

Curves are given to show how each variable changed with increasing current density in each solution tested. A curve is given showing the effect of varying the pH on cathode efficiency. In a 2 oz./gal. of Ni solution the cathode efficiency is about 98% from pH 4.5 to pH 3.25. Below pH 3.25 the cathode efficiency falls rapidly until at pH 1.5 the efficiency is only 10%. In the case of a 12 oz./gal. of Ni solution the efficiency remains high from 4.5 to 2.0 pH, when it starts to fall off reaching a value of 45% at a pH slightly less than 1.0. The author concludes from these tests that hot Ni solutions can be run at higher metal concentrations than those now employed (which is about 7 oz./gal.) Higher current densities and shorter plating times would thus be obtainable. GBH (8d)

Nickel-plating Practice Abroad. W. T. Griffiths. *Aluminium & the Non-ferrous Review,* Vol. 1, Dec. 1935, pages 103-104. Compares current practice in U. S. A. with that on the continent of Europe. JCC (8d)

The Effect of Oxidizing Agents on Nickel Deposition. I. Hydrogen Peroxide and Nickel Nitrate. A. W. Hothersall & R. A. F. Hammond. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 46, Feb. 15, 1935, pages 201-202; Mar. 1, 1935, pages 251-254. Slightly condensed from a paper read before a joint meeting of the Faraday Society and the Electrodepositors' Technical Society, Dec. 1934. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 70L/6. HBG (8d)

Electroplating (Traité de Galvanoplastie) J. Salauze. Dunod, Paris, 1935. Paper, 6½ x 10 inches, 679 pages. Price 139.60 Fr.

The first 4 chapters cover in clear and simple fashion the older theories of electrochemistry. Then follow 2 chapters on the theory of the formation of electrodeposits and the influence of different factors upon the deposit. Cleaning methods and plating equipment are treated. The chapter on testing of deposits is of considerable interest. The latter half of the book deals with the theory and practice of plating Au, Ag, Cu, Pb, Sn, Ni, Co, Fe, Cd, Zn, Cr, and some of the less common metals.

As is the case frequently with French books, this is a well organized summary of facts and theories secured by other investigators. A surprising amount of the material is from the Transactions of the American Electrochemical Society—a most excellent source. The emphasis is on theory; the practical electroplater will find little of use in his day to day problems. H. W. Russell (8d) -B-

RODINE

—MAKES PICKLING EFFICIENT

- UNIVERSAL ADOPTION. Rodine is cutting costs in 95 per cent of the country's pickling rooms.
- SAVES ACID AND METAL. Rodine more than pays for itself. By its use, economies of 30 to 60 cents per ton of metal pickled, are frequently gained.
- PREVENTS OVERPICKLING. Rodine eliminates pitting of the metal, minimizes acid brittleness, reduces rusting of pickled stock.
- SIMPLE TO USE. And by Rodine's use, the pickling operation is easily controlled and consistent in results.

Discussion on Chromium Plating Troubles. *Monthly Review American Electroplaters' Society,* Vol. 23, Jan. 1936, pages 38-46. Discussion at meeting of Electrodepositors' Technical Society, Birmingham, England, Nov. 1934. Suggested remedies for poor throwing power: (1) Increase of voltage to furnish more current to recessed portions of work although there is danger here of burning edges, (2) decrease of temperature as low as possible in the bright range, with the disadvantage of limiting current density, (3) maintenance of correct solution concentration, 250 g./l. (chromic acid) being favored, (4) increase of distance between anode and cathode, (5) use of auxiliary anodes, (6) use of a sulphate ratio of 100-130 to 1. On perforated articles, such as a tub overflow, Cr will not plate around the holes unless they are plugged. An easier method consists in placing an auxiliary anode behind the work. It is suggested that when Pb anodes are first placed in service they be given a coating of peroxide. Subsequent formations of Pb chromate can then be removed more easily. Peeling around soldered joints is attributed to melting of the solder under excessive polishing wheel pressure and was particularly noticeable in thin walled sections which quickly heated up and flowed the solder. Iridescent colors on Cr plate are stated to arise from sulphate content of the solution being too low. GBH (8d)

Control of Electroplating. *Steel,* Vol. 98, Jan. 27, 1936, pages 37-38; Feb. 3, 1936, pages 43-44, 69; Feb. 10, 1936, pages 36-38; Feb. 17, 1936, pages 44-45. Discusses: (a) relationship between weight of electroplated coating and its thickness; (b) recommended test for porosity; (c) determination of Ni, composite Cu and Ni, Cu, Cr, composite Cr and Ni, Zn and Sn, Ag, and Au coatings on ferrous and non-ferrous metals; and (d) a more flexible porosity test. MS (8d)

Economical Nickel Plating (Wirtschaftliches Vernickeln). Eugen Werner. *Oberflächentechnik,* Vol. 12, Sept. 17, 1935, pages 219-222. The 3 principal methods of Ni plating, i.e. ordinary plating in the stationary bath, rapid plating, and plating in the drum are discussed and their relative economical advantages compared. In all methods, to obtain good economy it is necessary that $NiSO_4$ is continuously formed at the anode and that the deposit has a certain fineness of grain. The hardness of the deposit must be such as to permit mechanical working without injury and the deposit must be favorable to easy Cr plating and must not peel. An ordinary stationary bath contains 75 g. Ni ammonium sulphate in 1 l. water with pH about 5.8. Increase in pH to 6.4 increases the throwing power of the bath, reducing it to 4.6 decreases the throwing power. Density of solution is 6-7° Bé, current density 0.3 amp./dm.^{2}, voltage 3.5, temperature 18° C. A thickness of 0.025 mm. is obtained in 7 hrs. A rapid plating bath must work at 50° C., the higher the electric conductivity of the bath the finer is the grain of the deposit. The compositions generally used are: 240 g. $NiSO_4$, 30 g. boric acid, 19 g. KCl in 1 l. water; or 240 g. $NiSO_4$, 120 g. $MgSO_4$, 30 g. boric acid; or 240 g. $NiSO_4$, 30 g. boric acid, 150 g. Na_2SO_4, 20 g. NaCl; or 200 g. $NiSO_4$, 100 g. $MgSO_4$, 10 g. NaCl, 50 g. Na_2SO_4, 0.1 g. NaF in 1 l. water. The current density must be adapted to the material to be plated. Pure Ni anodes do not dissolve as easily as 98% pure anodes. If the deposition velocity is too high an excess of O forms on the anode and passivates it and finally Ni bisulphate and peroxide are formed without Ni going into solution at all. Plating in the drum requires a pH of not less than 6.6, voltage is 8-12, time usually 2 hrs., bath temperature generally 35°-50° C. Ha (8d)

Electrode Potentials and the Form of Electrodeposited Metals. SAMUEL GLASSTONE. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1232-1237. Discussion page 1259. The author concludes that there must be some connection between the form of an electrodeposited metal and the electrode potential operative during the deposition. By reference to some of the factors involved it is shown that it is essential to analyze the experimental conditions to insure the absence of incidental factors which may obscure the results of any study to determine the connection referred to. 18 references. PRK (8d)

Influence of the Basis Metal on the Structure of Electrodeposits. A. W. HOTHERSALL. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1242-1247; *Engineering,* Vol. 140, Aug. 2, 1935, pages 127-128. Studies of the deposition of Cu, Ni and Sn on basis metals of Cu, brass, Ni, Fe, Sn, Sb and Ag showed that continuity of structure is possible when deposit and basis metal belong to the same crystal system with a range of differences in lattice parameters from —2.4 to +12.5%. Continuity of structure may also occur when deposit and basis metal belong to different systems. It appears probable that the high degree of adhesion obtained with electrodeposited coatings is associated with their ability to continue the crystal lattice of the metal base. 9 references. 8e. Metallic Coatings other than Electroplating

Electrolytic Iron Provides Bond in Cladding with Special Alloys. RAYMOND R. ROGERS. *Steel,* Vol. 98, Feb. 10, 1936, pages 34-35. Describes recently developed process for covering inexpensive metals such as steel with a veneer of stainless steel, high-speed steel, Ni, or Stellite. In cladding with 18-8 Cr-Ni steel, 2 plates of 18-8 are placed back to back with a thin separating layer of Na_2SiO_3 containing talc or MgO. Plates, after being welded together around edges and degreased, are pickled anodically in 6*N* HCl at ordinary temperature with an anode current density of 60 amp./ft.^{2} until entirely free from non-metallic material. They are then rinsed, thoroughly scrubbed, and pickled anodically in the same bath just long enough to remove non-metallic material formed during scrubbing and are placed immediately in Fe plating bath without removing adhering acid. Bath contains 40 oz./gal. $FeCl_2.4H_2O$, 45 oz./gal. $CaCl_2$ and just sufficient HCl to prevent formation of a precipitate. Temperature of about 195° F. and cathode current density of 60 amp./ft.^{2} are used. Under these conditions, Fe is deposited at rate of about 0.003"/hr. The Fe coated 18-8 "double plate" is placed between two slabs of backing material and the assembly of 4 is seam-welded around edges. Combination is heated for about 1 hr. at 1750° F. to produce fusion weld between electrolytic Fe coating and 18-8 steel. It is then heated to about 2100° F. and rolled. Finally, the welded edges are sheared off. In cladding with high-speed steel, if preliminary anodic pickling in 6*N* HCl is required, this is followed by anodic treatment in an alkaline bath until gas evolution is entirely uniform over whole surface. Ordinary temperature and current density of 25 amp./ft.^{2} are used. Steel is dipped in HCl and then plated. Remaining procedure is essentially same as in case of 18-8. Stellite is treated anodically in 12*N* HCl at room temperature and current density of 60 amp./ft.^{2} until it is covered by a dark blue material. After rinsing, it is pickled by alkaline anodic treatment given high-speed steel. It is then given a short HCl dip and plated. After plating, composite metal is seam welded to a piece of backing material and whole is heated for some time at about 1750° F. and pressed together. MS (8e)

Cementation of Iron and Ferrous Alloys with Beryllium (Cémentation du fer et des alliages ferreux par le glucinium) J. LAISSUS. *Revue de Métallurgie,* Vol. 32, July 1935, pages 293-301; Aug. 1935, pages 351-360; Sept. 1935, pages 401-422. Cementation experiments made previously by Feszczenko-Chopiwski and by Cazaud are described. Possibility of cementation is shown by Wever and Mueller diagrams for Fe-Be system, indicating a closed γ loop. At room temperature a solid solution of α Fe containing 1.5-2.0% Be can be expected together with a eutectoid containing about 9.2% Be. Specimens were packed in a cementation mixture, powdered 98% Be or 80% Fe-Be, contained in a cylindrical receptacle closed with threaded plugs. This was placed in a second closed box filled with charcoal and cast iron borings which was used for preventing access of O_2 to the samples. An electric furnace with an automatic control was used for heating. Sections of samples of electrolytic Fe cemented in Be powder showed a case consisting of: an inner zone of solid solution, a layer of solid solution containing some eutectoid and an outer zone of hypereutectoid alloy containing much $FeBe_2$. The diffusion mechanism observed during cementation of C steels was similar to that observed in electrolytic Fe except that a more complex structure was observed in the steel. The constituents of the case observed on C steels in the outward order were: (a) zone with gradually decreasing pearlite content, (b) practically decarburized layer, (c) solid solution Fe-Be-C, (d) sharply defined hypoeutectoid layer of solid solution Fe-Be-C and a triple eutectoid, (e) eutectoid zone and (f) hypereutectoid zone. Cementation with 80% Fe-Be produced the same results as pure Be. For electrolytic Fe, the thickness of the case varied with the temperature, particularly above 1000° C., and with cementation time. 10-hour cementation at 1100° C. produced a 0.7 mm. case. In higher C steels the thickness of the decarburized layer passed through a maximum with increasing temperature and increased with cementation time, provided it was longer than 5 hours. The thickness of other layers increased directly with the temperature and time. For the same time and temperature C content had a retarding action on the depth of diffusion. Time effect did not depend on the composition of the base, though with 0.9% C the thickness of case ceased to be proportional to time. Hardness of case increased with C content, but is not a direct function of the temperature. Electrolytic Fe yielded 268 Vickers case, 0.9% C steel had a case with 1506 Vickers. Cementation with Be reduced the resistance of steel to scaling. It increased the resistance of steel to atmospheric corrosion, to the attack of fresh and salt water and to bleaching liquor. Good protection against HNO_3 was produced, provided the case was not cracked. Corrosion resistance to all other reagents studied was decreased. See also *Metals & Alloys,* Vol. 6, Mar. 1935, page MA 120R/8. JDG (8e)

Protective Coatings (Les revêtements protecteurs). J. COURNOT. *Métaux,* Vol. 9, Oct. 1934, pages 495-497. General discussion of preparation of materials for application of protective coating. GTM (8e)

Metallization (La Métallisation). S. FRANCOIS. *Métaux,* Vol. 9, Oct. 1934, pages 526-534. For coating by hot-processes immersion of the objects in a bath of molten metal is generally used, Zn at 500° C., Sn at 260° C. The Schoop procedure of metallization by spraying, a competitor in this field, has been thoroughly studied and discussed in literature to which one is referred. 69 references. GTM (8e)

Protection of Magnesium by Selenium Coatings (La protection du Magnesium par les revêtements de selenium). HENRI FOURNIER. *Métaux,* Vol. 9, Oct. 1934, pages 506-508. 9 references. Principle of method for applying Se coatings on Mg or light alloys consists in immersing the material in a solution containing selenious acid (free or salt) which, being very unstable, is reduced to metallic Se and deposited on the material. Many methods have been tried, and the following found to give similar results: (1) Immersion for 3 hours in an aqueous solution of 8% Na selenite, 3.2% selenious acid and 0.10% NaCl at 80°-90° C. (2) 10% selenious acid solution with 0.1-0.5% NaCl for 5-10 minutes. (3) 2% Na selenite solution with 0.2% H_3PO_4 for 1 minute. (4) Initial cleaning for 30 seconds in 1% chromic acid at 80° C. and then treated as in method 3. (5) Identical cleaning as in method 4 followed by method 2. GTM (8e) have

Cementation of Some Metals by Means of Chromium Powder. Tsutomu Kase. *Kinzoku no Kenkyu,* Vol. 12, July 1935, pages 357-390. In Japanese. The cementation of Fe and Ni with powdered Cr at temperatures between 800°-1300° C. was investigated. Studies were made of the depth of penetration, chemical composition, corrosion resistance to certain acids, microstructure, and resistance to oxidation. The following results were observed:—Diffusion of Cr into Fe and Ni commences at a temperature of 700° C, and the rate of diffusion increases with the rise of temperature, the increase being especially marked above A_3 (906°) for Fe. The relation between the weight increase, or the depth of penetration of the specimen and temperature of the cementation can be given by an exponential function,

$$W = a e^{\frac{-b}{T}}$$

where W denotes the weight increase, T the absolute temperature and a and b constants. The curve breaks into 2 branches at A_3 in the case of Fe. Similarly, the relation between the weight increase or the depth of penetration and the duration of cementation is given by an exponential function. The surface layer of Ni cemented with Cr resists oxidation at high temperatures as the alloy Nichrome does and also resists well corrosion by HNO_3. KT (8e)

Some Fundamental Considerations on Tinplate. W. E. Hoare. *Sheet Metal Industries,* Vol. 9, Apr. 1935, pages 201-204. Discussion of normal and potential pores in the tin coating pointing out the possibility that pores may develop from grease lines, mottle and dry patches and isolated $FeSn_2$ crystallites. AWM (8e)

The Use of Aluminium in Hot-Galvanizing. Heinz Bablik. *Aluminium & the Non-Ferrous Review,* Vol. 1, Oct. 1935, pages 9-10. Addition of Al in quantities of 1-2% to Zn in a hot-galvanizing bath gives a brighter and more flexible coating. A "dry" process, in which sheets are dipped in zinc chloride solution and dried before dipping is necessary; the usual salammoniac flux should not be used on the bath as it reacts with Al. JCC (8e)

8f. Non-Metallic Coatings

Effect of Clays on the Opacity of White Enamel for Sheet Steel. R. R. Danielson. *Journal American Ceramic Society,* Vol. 19, Feb. 1936, pages 59-61. Effect of various types of clays on reflectance is shown, the variation may be 5% in some cases. When opacity and suspension of the clay in the enamel are important, a blend of clays having both properties may be used to improve workability in the draining or dipping of ware. WB (8f)

New Knowledge in the Lustrous Hot Coloring (of Metals) (Neue Erkenntnisse in der Lüstersudfärbung) G. Gross. *Zeitschrift für Metallkunde,* Vol. 27, Oct. 1935, pages 238-241. Metals may be given a lustrous colored finish ranging from yellow through brown to dark blue by dipping in a hot (80-95° C.) water solution of 124 g. $Na_2S_2O_3 . 5H_2O$ and 38 g. $Pb (C_2H_3O_2)_2 . 3H_2O$/l. This colors Cu, dark blue; Zn-bronze, brown; and Fe or steel, blue. Intermediate tones may be obtained by controlling the length of the dipping period. It is found that a more uniformly colored, denser, finer grained and more adherent coating is obtained by lowering the bath temperature and increasing the time accordingly. The time of dip required under these circumstances may be decreased materially by increasing the concentration of $Na_2S_2O_3 . 5 H_2O$, decreasing the quantity of $Pb (C_2H_3O_2)_2 . 3 H_2O$ and adding a weak acid such as acetic or argol. An old bath works faster than a new one. With a bath composed of 240 g. $Na_2S_2O_3 . 5 H_2O$. 25 g. $Pb (C_2H_3O_2)_2 . 3 H_2O$, and 30 g. argol/l. H_2O, it is possible to obtain a satisfactory tint on 63-37 brass in 12 minutes at room temperature. The results of a study of the influence of bath composition, temperature, time of dip and color are presented in graphical form. Discussion by Masing, Fischer, Gross, and Sterner-Rainer. FNR (8f)

Anodic Treatment and Dyeing of Aluminum Castings. N. D. Pullen. *Proceedings Institute of British Foundrymen,* Vol. 26, 1932-1933, pages 335-345. See *Metals & Alloys,* Vol. 5, Mar. 1934, page MA 105; July 1934, page MA 342; Oct. 1934, page MA 486. CEJ (8f)

A Method and Apparatus for Studying the Physical Properties of Vitreous Enamels on Steel. J. E. Rosenberg & A. Langerman. *Journal American Ceramic Society,* Vol. 19, Mar. 1936, pages 86-90. A split steel ring was enameled and fired, the ring being restrained from change in diameter during firing. The size of the opening when restraint was removed after firing gives an indication of stresses due to difference in coefficient of thermal expansion of enamel and steel. Stresses resulting from enamel applied to outside of ring and stresses produced by varying thicknesses of enamel coating were measured by amount of contraction of the ring. Theoretical considerations are discussed and method shown for obtaining absolute values of stresses required to close the ring after enameling. WB (8f)

Will you take a
DARE?

THEN test Ryerson V. D. against your highest priced water hardening Tool Steel. Compare results. Compare prices. Thousands of our customers have found that Ryerson V. D. steel will get harder—change shape less—and retain a finer grain structure when over heated than most other water hardening steels.

V. D. Steel will reduce your costs and give equally good or better results. If skeptical, write for a free test sample.

RYERSON

Chemical Developments in the Finishing Industries. J. M. Fain. *Metal Cleaning & Finishing,* Vol. 7, Mar. 1935, pages 117-120. Sprayed coatings of asphalt emulsions are being used on inside of automobile bodies to prevent rattling noises. Emulsion is made by pouring melted asphalt into a mixer together with a clay slip (bentonite). When the emulsion is applied as a surface coating, the asphalt separates out. This method of applying asphalt has worked in places where hot asphalt could not be used, such as on moist surfaces. Rubber-base paints are also discussed, good adhesion being claimed for them. Chlorinated rubber base paints have superior merits of resistance to acids and alkalies and strong adhesion to metal and concrete. GBH (8f)

Electron Diffraction Examination of Protective Films Deposited on Magnesium and Magnesium Alloys by the R.A.E. Dichromate Process. H. G. Hopkins. *Journal Institute of Metals,* Vol. 57, No. 2, 1935, pages 227-230. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 22R/1. (8f)

Investigations of the Phosphate Protection of Iron Obtained with the Biphosphates of Zinc, Iron, Manganese (Ricerche sulla Protezione fosfatica del Ferro ottenuta con Fosfati biacidi di Zinco, Ferro, Manganese) O. Macchia & G. Boggio. *Industria Meccanica,* Vol. 17, Sept. 1935, pages 817-821; Oct. 1935, pages 906-909; Nov. 1935, pages 991-995. Numerous tests were made to find the principal factors which determine the protective action of phosphate coatings against atmospheric influences with solutions of the biphosphates of Fe, Zn, Mn, Fe-Zn, Fe-Mn, Zn-Mn. The general conclusions can be summarized as follows: Zn phosphate solution, about 3.0%, offers a good protection but requires too long time (55 min.) for its action. Solutions with 3.5% Mn biphosphate are good, and more rapid. Fe biphosphate cannot be used as it affords no appreciable protective value. Fe-Zn biphosphate solutions of 3% give excellent protection. Zn-Mn biphosphate in 4% concentration and high in Mn biphosphate is satisfactory both from the point of view of protection and duration. Fe-Mn biphosphate solutions having 3.5% concentration and more than 70% of the solute consisting of Mn biphosphate give the best results both in behavior of the protective surface and in rapidity of treatment. The last is recommended for practical applications. Procedures are described in detail. 41 references. Ha (8f)

Optical Research on Evaporated Metal Layers. L. S. ORNSTEIN. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1158-1168. Includes discussion. It is shown how total reflectivity can be found in a single experiment. The accuracy of the absorption is entirely independent of the form and condition of the surface. The generalization that if a piece of any material is illuminated homogeneously, the ratio of the intensity of the light leaving the material in a particular direction A to the intensity of the incident light is equal to $I - a_A$ where a_A represents the total absorption for the light incident along A. There have yet to be investigated errors which may arise in the proposed experiment if the illumination is not perfectly homogeneous.

C. S. BARRETT, SECTION EDITOR

Stress Analysis by X-ray Diffraction. C. S. BARRETT & M. GENSAMER. *Physics,* Vol. 7, Jan. 1936, pages 1-8. A general mathematical treatment of the problem of determining surface stresses in a metal by means of X-rays is given. Included as special cases are the determination of uniaxial stresses or the sum of 2 principal stresses in the plane of the metal surface, and the treatment is extended to determining each of these 2 individually. The optimum operating conditions are given and probable errors evaluated. Under the best conditions these should be about 1300 lbs./in.^{2} for Fe and 320 lbs./in.^{2} for duralumin. Various camera designs are suggested and the practical applications discussed.

What Is a "Pock-Mark" in Steel? J. S. GLEN PRIMROSE. *Edgar Allen News,* Vol. 14, Feb. 1936, page 797. So-called "pock-marks" appear on the fractured surface of pulled test bars and are small dark colored dots with radial markings set in the lighter gray face of the steel. By cutting longitudinally through these marks and etching and polishing the section one can recognize that there was evidently a slag inclusion or some P at that place. As the material is less ductile at that point, fracture starts there.
Ha (9a)

Some Unusual Causes of Shaft Failures. Edward Ingham. *Mechanical World & Engineering Record,* Vol. 98, Nov. 22, 1935, pages 498, 502. In many cases the causes of shaft failures are hard to find. Unless the real reasons are established there is a tendency for over expense in corrective measures. Examples are given which will afford a lead for examining obscure cases. WH (9a)

Detection of Oxide Inclusions in Steels by Imprint Methods (Ueber den Nachweis von Oxydeinschlüssen durch Abdruckverfahren) R. Mitsche. *Berg- und Hüttenmännisches Jahrbuch,* Vol. 83, Dec. 23, 1935, pages 127-133. The practical importance of detecting non-metallic inclusions in steel is explained and the method of M. Niessner described which permits making photographic prints of iron oxide inclusions. A gelatine-coated paper is impregnated with a solution of HCl in H_2O (1 : 20), the section then pressed onto the paper and the latter developed in a ferrocyanide potassium solution (20 g./l. H_2O). Influence of kind of gelatine paper, developing conditions and least magnitude which can be detected are discussed. Ha (9a)

Sampling and Inspecting Steel. J. H. Hruska. *Heat Treating & Forging,* Vol. 22, Feb. 1936, pages 71-73. Deals with determination of quality of ingot-steel. Discusses test ingots; taking drillings for chemical analysis; macrographic etching of ingot sections; sulphur printing; fracture tests; and shear tests. MS (9a)

Failure of Parts in Service. Eugene W. Nelson. *Heat Treating & Forging,* Vol. 22, Feb. 1936, pages 63-65. Discusses briefly fractures caused by torsion, shear, impact, compression, bending, and fatigue, with chief attention to the last. Outlines theories of fatigue failure by slip and by stress raisers. MS (9a)

Industrial X-Ray Practice. Robert C. Woods. *Electronics,* Vol. 9, Feb. 1936, pages 7-11. A review of the present-day uses of X-rays in production, testing, inspection, and industrial research. Contains some practical information on the necessary equipment and the cost of its installation. DJM (9a)

X-ray Testing of Welds. II. E. L. Mathy. *Industry & Welding,* Vol. 8, Jan. 1936, pages 31, 34-35. Testing principles for X-rays and gamma rays, and protection for the operator from the harmful effects of the rays are explained. Ha (9a)

Absorption of Short Wave-length X-rays. W. V. Mayneord & J. E. Roberts. *Nature,* Vol. 136, Nov. 6, 1935, page 793. Measurements of mass absorption coefficients of 18 elements for X-rays from 250 kilovolt constant potential X-ray tube when filtered through 3 mm. Pb, 2 mm. Sn, and 3 mm. Al. CSB (9a)

The Relation Between Density of Blackening and X-Ray Intensity for Characteristic Copper Radiation and Agfa-Laue Film. F. D. Miles. *Transactions Faraday Society,* Vol. 31, Oct. 1935, pages 1452-1460. The density of blackening of Agfa-Laue film by characteristic Cu radiation may be taken to be proportional to the X-ray intensity up to a density of 1.0. The error involved is at the most 4% of the highest density measured. There is no evidence of threshold effect. 13 references. PRK (9a)

International Standardization of Notched Bar Impact Test. Experimental Study of the Influence of the Depth of Notch (Normalisation internationale de l'essais de flexion par choc sur barreaux entaillés. Etude expérimentale de l'influence de la profondeur d'entaille) Etienne Dupuy, Jacques Mellon & Pierre Nicolau. *Revue de Métallurgie,* Vol. 33, Jan. 1936, pages 55-70; Feb. 1936, pages 133-139. Committee 17 of the International Standards Association proposed during its meeting at Düsseldorf in 1933 the standardization of the shape of the impact bars used for determination of impact strength. The dimensions of 10 x 10 x 55 mm. were generally agreed upon as well as the U-shaped notch with a radius of 1 mm. The depth was left open until further study. The present investigation determines the influence of this depth. 5 alloy and 5 plain C steels all properly heat treated to give the widest possible range of impact values were used as samples. Impact test bars were cut of hot rolled stock in a way to produce the most representative samples, machined almost to size, heat treated, machined to size and notched. Both U-shaped and V-shaped notches were used, the latter was a 90° notch with an 0.25 mm. radius. They were tested at room temperature in a Charpy machine. The depths of U-notches studied were 2, 3, 4, 5, 6, 7, 8 mm. and of V-notches 3 mm. A further study included U-notches which had depths of: 0, 0.6, 1.3, 2, 3, 4, 5, 6, 7, 8, 8.6 and 9.2 mm. The results obtained are given in figures and curves. They were compared with data of A. Steccanella, *Metallurgia Italiana,* Feb. 1935, page 81, and of R. Mailänder *Stahl und Eisen,* Vol. 55, 1935, pages 749, 779. When the fracture is coarsely crystalline, the depth of a notch does not have any effect. When specimens break with a tough fracture, the impact value is a linear function of the depth of the notch, $K = K_1 + Ah$ where K_1 is a constant which can be considered in the first approximation as independent of the nature and state of the metal. With greater depths of h and with tough steels the values obtained deviate upwards from the theoretical, the more the higher is the impact strength of the steels. In brittle steels lower values of h tend to raise curves which apparently corresponds to the influence of a tough surface layer. Scattering of relative values obtained on carefully machined samples is independent of the depth of the notch, but the absolute values are substantially proportional to h. Any depth of notch leads to the same classification of steels. V-notch used in these experiments gives the same results as U-notches. For the same depth of notch, impact strength is diminished by V-notch. The ratio between impact strength obtained with a 5 mm. U-notch and a 3 mm. V-notch is slightly greater than 1 up to $K = 9$. Above this the ratio drops below 1 and decreases rapidly. A 10 x 10 x 55 mm. test bar with a U-notch 5 mm. deep has a marked superiority over the same bar with a 2 mm. U-notch. The same bar with a 3 mm. U-notch does not offer any special advantages but very tough steels call for a special notch. JDG (9b)

Behind Southwark Testing Machines and Instruments stands not merely the limited experience of one manufacturer, but, rather, the accumulated scientific knowledge of a large part of the testing engineering profession.

In this connection Southwark may point to their close association with such eminent authorities as the directors of research of leading colleges and engineering schools, testing officials of many bureaus of the national, state and municipal governments, and prominent men engaged in the research laboratories of leading industrial plants.

Reflecting the influence of these "first minds" of the engineering world—Southwark testing machines and instruments always represent the most advanced thought in testing practice, meeting every up-to-the-minute routine or research testing requirement.

This is the reason why it would be difficult to find a modern testing laboratory today that is not using one or more types of Southwark Testing Equipment listed above.

Photoelastic Study of Stresses Due to Impact. Ziro Tuzi & Masataka Nisida. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Vol. 21, Feb. 1936, pages 448-473. A cinematographic method of photographing impact phenomena on vibrating specimens of phenolite with exposures of 1/5000-1/50,000 sec. is described. The max. stress produced by impact was found to be 80-90% of the calculated value. See also *Metals & Alloys*, Vol. 6, Sept. 1935, page MA 368R/8. Ha (9b)

Study of Forging Qualities. Investigation of Laboratory Testing (Contribution a l'étude de la forgeabilite recherch d'un essai de laboratoire) Albert Portevin, Etienne Pretet & Jean de Lacombe. *Revue de Métallurgie*, Vol. 33, Feb. 1936, pages 114-132. Steels containing 0.08% C, 0.32 Si, 0.31 Mn, 0.020 S, 0.018 P, 0.14 Cu; 0.03 C. 0.02 Si, 0.1 Mn, 0.018 S, 0.002 P, 0.012 O; 0.08 C, 0.43 Si, 1.39 Mn, 40.78 Ni; 0.03 C, 0.3 Si, 0.015 Mn, 40.70 Ni; 0.40 C, 1.31 Si, 0.08 Mn, 12.35 Cr, 13.16 Ni, 2.25 W and brasses with 58.80 Cu, 38.18 Zn, 1.64 Pb, 0.52 Sn, 0.70 Fe; 64.90 Cu, 34.50 Zn, 0.04 Pb, 0.06 Fe, 0.07 Sn were tested for torsion, compression, bending, tensile strength, impact strength and compression by an impact. Steels were tested at intervals of 100° between 600° and 1300° C., brasses between 300° and 800° C. Curves for the properties obtained are given. The results obtained cannot be interpreted using a uniform method. Special considerations should be applied to every different case. JDG (9b)

Dynamics of the Tensile Test (Zur Dynamik des Zerreissversuchs) W. Späth. *Messtechnik*, Vol. 12, Feb. 1936, pages 21-25. The tensile test is a static test strictly, only over the elastic range of the specimen, beyond this range flow phenomena occur which make the test an entirely dynamic one. The oscillations in the machine and specimen in this range are explained and the theory for machines with weights and hydraulic testing machines is developed. Conditions can be set up during a test, especially in the former class, where the specimen is subject to considerably higher stresses than calculated in the usual manner for static conditions. Improvements in the design of testing machines are suggested to reduce oscillations as much as possible. Ha (9b)

Marblette for Photoelastic Models. A. G. Solakian. *Product Engineering*, Vol. 7, Mar. 1936, page 107. A new material called "Marblette" of high mechanical strength and optical sensitivity for transparent models for photoelastic tests is described. The available materials for this purpose, and the stress in lbs./in.² to produce one fringe/in. of thickness, and the strength in lbs./in.² are:

Material	fringe stress	elastic limit
marblette	23	2750
phenolite	55	7000
bakelite	70	5500
celluloid	205	4000
glass	1150	——

Marblette is a phenolic material which can be obtained in liquid or plastic form and cast to shape. Ha (9b)

Sectional Strength (Die Gestaltfestigkeit) A. Thum & W. Bautz. *Stahl und Eisen*, Vol. 55, Sept. 26, 1935, pages 1025-1029. The suitability of a material for machine parts depends very largely on the shape of the section and the type of notch effect involved. Test pieces of various materials should, therefore, be made and tested, having the actual shapes to be used. The notch sensitivity of the material should also be determined. SE (9b)

General Survey of Tests for Determining Properties of Aluminum Castings (Coup d'oeil général sur les éssais effectués en vue de determiner les charactéristiques des pièces de fonderie en aluminium) A. von Zeerleder. *Revue de Métallurgie*, Vol. 33, Jan. 1936, pages 1-6. Tensile testing is the best method for evaluating properties of castings, but multiplicity of factors entering casting practice makes representative sampling very difficult. Separately cast test bars made under rigidly standardized conditions appear to be more advantageous, particularly when they are cast in a horizontal position. JDG (9b)

A Deep-drawing Test for Aluminium. A. G. C. Gwyer & P. C. Varley. *Journal Institute of Metals*, Vol. 58, Jan. 1936, pages 7-16 (Advance Copy No. 715). A newly developed test for determining the deep-drawing qualities of Al and Al alloys is described. It consists in 2 drawing operations, in which the first is a cupping operation and the second is a redraw of the cup formed. The test distinguishes between different tempers of the metal. The test proved that Al sheet of medium tempers had very good drawing properties and it is suggested that medium-temper sheet should be used more extensively for deep drawing. 11 references. Relationships in Cast Iron Test Results. G. L. Harbach. *Engineer*, Vol. 160, Sept. 6,1935, pages 251-252. See *Metals & Alloys*, Vol. 7, Mar. 1936, page MA 139L/2. LFM (9b)

Effect of Stretching and Aging on the Behavior of Steel Under Alternating Stresses (Einfluss von Recken und Altern auf das Verhalten von Stahl bei der Schwingungsbeanspruchung) F. Körber & M. Hempel. *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung*, Vol 17, No. 22, 1935, pages 247-257. Experiments on the effect of thermal and mechanical aging of cold-deformed steels (5 and 10%) on the static tensile strength and alternating strength under bending and tension-compression stress, on the damping qualities of the material and on metallographic and X-ray tests are reported. A cold-deformation of 5-10% without aging treatment reduces notch-toughness considerably; thermal aging reduces this value still more. Aging treatments have different effects on the mechanical properties, this is very likely due to the fact that thermal and mechanical (natural) aging must be ascribed to different causes. The tests are described in detail. 24 references. Ha (9b)

International Standardization of the Notched-Bar Impact Specimen (Internationale Vereinheitlichung der Probenform für Kerbschlagversuche) R. Mailänder. *Stahl und Eisen*, Vol. 55, Dec. 5, 1935, pages 1456-1458. A series of test results are given to check the results of A. Steccanella on 10 x 10 x 55 mm. notched-bar impact specimens with 2, 3, and 5 mm. deep notches. The scatter was about the same for all 3 types. The German specimen with 1 mm. diameter notch appears to possess no advantages. SE (9b)

Model Experiments in Stress Distribution. William Hope Harnett. *Journal & Transactions Institution of Engineers of Australia*, Vol. 7, Oct. 1935, pages 345-354. The paper reviews a number of methods in which models are used for the experimental study of complicated stress distributions, special attention being given to application of photo-elasticity and to recent developments in "analogy" methods. WH (9b)

Measurements on the Open-hearth Furnace (Messungen am Siemens-Martin-ofen) W. Liesegang. *Archiv für Technisches Messen*, Vol. 5, Dec. 31, 1935, pages T165-T166. Correct arrangement of temperature measurements in furnaces, in particular the open-hearth furnace, is explained; measurements must be made (1) to obtain rapidly the maximum admissible temperature required for the process, (2) to insure the greatest possible uniformity of temperature on the hearth, (3) to prevent the recuperating or regenerating installation from becoming too hot, and (4) to avoid uneconomical utilization of the waste gases. Arrangement and types of instruments to use for temperature, pressure and draft measurements, for gas and air quantities, and for gas analyses are discussed. 16 references. Ha (9b)

Which Form of Test Piece is Best Suited for Impact Tests (Vilken slagprovstav har utsikt att sla igenom som normalstav?) Gunnar Malmberg. *Jernkontorets Annaler*, Vol. 119, Nov. 1935, pages 455-482. The author concludes that a test piece 10 x 10 x 55 mm. with a slit in the center of 3 mm. depth and 2 mm. width is preferable because it gives more consistent readings than test pieces with slits of the same width but depths of 2 mm. or 5 mm. HCD (9b)

Actual Problems in Testing Methods for Light Metals (Aktuelle Probleme bei Prüfungsmethoden von Leichtmetallen) M. Ros *Aluminium*, Vol. 17, Dec. 1935, pages 631-637. The present status of technological testing of light metals, the various methods and their particular purpose are discussed and classified, terms defined and the preparation of test specimens described; the dimensions are given in sketches. It is emphasized that material testing and experience are one indivisible unit; the testing of materials in the laboratory, supervision during production and manufacture, and experience made on the finished structure must always be correlated to obtain the greatest benefit for the progress of industry. Ha (9b)

The Problem of Retirement of Wire Rope from Service. B. M. Suslov. *Wire & Wire Products*, Vol. 11, Jan. 1936, pages 19-21, 48. An outline is given of Russian practice to determine the life of a wire rope so that it can be replaced in time. The method to determine the degree of deterioration of a stranded rope is based on the investigations of R. Woernle and is described in full. Ha (9b)

9c. Fatigue Testing

H. F. MOORE, SECTION EDITOR

The abstracts appearing under this heading are prepared in cooperation with the A.S.T.M. Research Committee on Fatigue of Metals.

The Load-Deflection Fatigue Test. A Critical Investigation of Its Application to Steels. J. W. CUTHBERTSON. *Iron & Steel Institute, Carnegie Scholarship Memoirs,* Vol. 24, 1935, pages 1-50. A load-deflection short time test is described. This enables fatigue values of ferrous materials to be determined which are in excellent agreement with the true endurance limits. The test is satisfactory up to temperatures of 300° C. The best results are obtained when: (1) The specimen is first subjected to a preliminary treatment in which an alternating stress approximately equal to the fatigue value is applied until a constant strain is reached. Usually about 200,000 reversals are satisfactory, and at 2500 r.p.m. the time required is about 1 hour. (2) The amplification system is such as to allow the deflection of the end of the bar to be measured to less than 0.00005". (3) The specimen is uniformly stressed over a considerable portion of its length. Solid rod specimens suitably tapered over the center portion of their length were found to fulfill this condition quite satisfactorily. In addition, the author shows that deflection tests under constant load may be useful in rapidly determining fatigue values. Less than 4 hours is usually sufficient to indicate whether the applied stress is above, below, or equal to the fatigue stress. Hollow specimens such as were used by the author are not recommended since easily produced solid rods of similar dimensions give practically as satisfactory results. The materials studied were plain C, Ni case-hardening, and stainless steels. Stainless Fe was also tested. The stress frequency was usually 2500 r.p.m., and the continuous rate of loading was 1 lb./min. in most of the load-deflection tests. Rates of loading between 0.5 and 1.5 lbs./min. gave the best results. The author believes that the disappointing results obtained using certain non-ferrous metals and alloys in load-deflection tests are largely due to a poor definition of the exact point at which the load-deflection curve departs from linearity, and therefore he believes that if the factor of strain amplification were increased, much closer agreement between the load-deflection fatigue and true endurance values would result. 19 references. (Note by H.F.M. The load-deflection test as well as various other short-time tests have been found by various investigators to be fairly reliable in determining the fatigue limit for the ordinary ferrous metals. So far none of these short-time tests have proven reliable for determining the fatigue limits of non-ferrous metals. It is to be hoped that the author will make careful tests on some non-ferrous metals (including duralumin) and on austenitic steel. Until such data are available it is difficult to accept the load-deflection test as superior to several other proposed short-time tests for fatigue strength, or to regard any of them as reliable for general use). CW (9c)

Endurance Tests on Welded and Brazed Joints (Essais de Fatigue sur Assemblages Soudés et Brasés) L. DOUSSIN. *Bulletin de la Société des Ingénieurs Soudeurs,* Vol. 6, Nov.-Dec. 1935, pages 1939-1959. Lecture before the French Welders' Society. Tests have been made on Cr-Mo steel. Results deal with the following points: (1) Effect of temperature on endurance limit. For fusion welding it is difficult to establish decrease of endurance limit due to temperature. For bronze welding, endurance limit is 13.5-15.5 kg./mm.^{2}, for brazed tubes 16 kg./mm.^{2}, for silver brazing 13.7 kg./mm.^{2} on steel and 11.3 kg./mm.^{2} on brass. With soft solder, higher endurance limit obtained is 20.3 kg./mm.^{2} (2) Effect of stress distribution at points of thickness changes (when reinforcing sleeve is used). (3) Effect of over-lapping length and of joint length. Study leads to conclusion that static tests cannot give a value for endurance limit, a conclusion in accord with the findings of many previous investigators. All kinds of joining give a sufficiently high endurance limit so that none of them has to be discarded even the old ones which have been superseded by up to date joining processes. FR (9c)

Endurance Testing (Bemerkungen zur Durchfuhrung von Dauerversuchen) W. SPÄTH. *Metallwirtschaft,* Vol. 15, Jan. 24, 1936, pages 91-93. In determining the endurance strength by decreasing and increasing loads the latter method gives higher results. A model, consisting of a spring bridge balanced by a resistance element, is used to analyze the 2 testing methods and determine which is most valid. With decreasing loads 2 effective forces exist, the decreasing internal stress and an increasing force due to overstress at imperfections. Quite variable results will be obtained as the damping characteristics of the material must become constant. With increasing loads the critical internal stress is not exceeded locally, self-hardening occurs, and a value is obtained which is much more closely related to equilibrium conditions. This sort of self improvement of the material may be obtained by either static or dynamic loading and might well be used in practice. (Note by H.F.M. It seems doubtful whether endurance strength under repeated loading could be determined by the method outlined. The "self improvement" of the metal to which reference is made is probably due to cold work, and this improvement often overbalances the damage due to the beginnings of a spreading crack during the first few hundred applications of load. It is difficult to see how the test method outlined above could be used to detect the early stages of a spreading fatigue crack). GD (9c)

Calculation of the Endurance Limit of Notched Bars from the Tensile Strength and Reduction of Area (Berechnung der Kerbdauerfestigkeit aus Zugfestigkeit und Einschnürung) G. ERBER. *Archiv für das Eisenhüttenwesen,* Vol. 9, Aug. 1935, pages 95-97. On the ground that the endurance limit of notched bars depends both on the ordinary tensile strength and the deformability, the repeated impact resistance is expressed as a function of the tensile strength × the reduction of area. Data taken from the literature on various C and alloy steels appeared to indicate that for certain values of the tensile strength × reduction of area the endurance limit of notched bars can be calculated to within about ± 10%. (Note by H.F.M. The suggestion of determining fatigue strength from the results of a static tension test has frequently been made, and various methods have been devised which give fairly good indications of fatigue strength for the common ferrous metals. However, none of the methods with which the writer of this note is aware have been found reliable for non-ferrous metals, and their reliability for such ferrous metals as the austenitic steels is not yet proven). SE (9c)

9d. Magnetic Testing . . .

L. REID, SECTION EDITOR

Relation of Temperature to Spontaneous Magnetization (Über die Sogenannte Temperaturabhängigkeit der Spontanen Magnetisierung) KOTARÔ HONDA & TAMOTSU NISHINA. *Zeitschrift für Physik,* Vol. 98, Feb. 3, 1936, pages 657-665. Theoretical aspects of magnetic forces are discussed from measurements made of the residual magnetism of a single Fe crystal across the 3 principal axes at different temperatures. FHC (9d)

Magnetic Properties and Orientation of Ferromagnetic Particles. II. Pyrrhotite. C. W. DAVIS. *Physics,* Vol. 6, Dec. 1935, pages 376-379. The changes of magnetic properties of granular pyrrhotite by particle orientation and heat treatment are discussed and attendant data given. Heat treatment, while causing no chemical change in this mineral, causes increased induction and remanence and decreased coercive force. Particles aligned parallel to the magnetizing field show greater induction and remanence but less coercive force than randomly oriented particles. Cross-oriented particles showed lowest induction and remanence but the greatest coercive force. The effect of orientation on the magnetic properties is different for pyrrhotite than for magnetite. HFK (9d)

Coercive Force of Magnetite Powders. V. H. GOTTSCHALK. *Progress Reports—Metallurgical Division. 10. Mineral Physics Studies. United States Bureau of Mines, Report of Investigations* No. 3268, Feb. 1935, pages 83-90. See *Metals & Alloys,* Vol. 6, Sept. 1935, page MA 369L/9. AHE (9d)

Magnetic Properties, Report of Committee A-6. THOMAS SPOONER, Chairman. *Proceedings American Society for Testing Materials,* Vol. 35, Part I, 1935, pages 104-106. Progress report. VVK (9d)

Change in Magnetic Susceptibility of Metals During Melting and Allotropic Transformation. K. HONDA & Y. SHIMIZU. *Nature,* Vol. 136, Sept. 7, 1935, page 393. New measurements, in vacuum, of the changes with temperature of magnetic susceptibility of Sn, Cu, Au, Ag and comparison of results with theories. CSB (9d)

Magnetism of Copper. S. RAMACHANDRA RAO. *Nature,* Vol. 136, Sept. 14, 1935, page 437. The magnetic susceptibility of colloidal Cu is greater than that of the massive metal. The critical diameter below which the susceptibility increases rapidly is 0.8 μ. Colloidallization has the same effect as cold working. CSB (9d)

Diamagnetism of Thallium Single Crystals. S. RAMACHANDRA RAO & K. C. SUBRAMANIAM. *Nature,* Vol. 136, Aug. 31, 1935, pages 336-337. Magnetic susceptibility of Tl is 0.407 (10^{-6} units) parallel to hexagonal axis and 0.163 perpendicular to it, giving unusually large anisotropy. The average for polycrystalline Tl is 0.244. Upon transformation of the crystal to the cubic system at 235°, susceptibility suddenly becomes isotropic at 0.170; a further decrease to 0.153 occurs on melting (302° C.). CSB (9d)

Abnormal Magnetic Behavior of Treated Cobalt Wire. T. F. WALL. *Nature,* Vol. 136, Sept. 7, 1935, page 397. A Co wire was heated for a few seconds at 1200° C. in H_2 by a 50-cycle alternating current. After cooling the saturation value of the intensity of magnetization and the maximum permeability is increased. If the treatment is continued several hours the saturation magnetization is reduced to 60% of normal and the maximum permeability is lowered greatly. CSB (9d)

9e. Spectrography

Spectroscopic Analysis of Steels—The Influence of Non-Homogeneous Samples. W. R. BRODE. *Proceedings American Society for Testing Materials,* Vol. 35, Part II, 1935, pages 47-52, discussion pages 53-56. Detailed data are given on a series of composite samples and lines determined for Sn, Ni, Mn, Cr, and Cu. A comparison is made between the log-sector and the density-photometry methods. VVK (9e)

The Use of the Spectrograph in the Platinum Industry. H. E. STAUSS. *Proceedings American Society for Testing Materials,* Vol. 35, Part II, 1935, pages 57-60. The use of the spectrograph in the Pt industry is discussed from the standpoint of (1) identification of alloys, (2) special analyses for minor impurities, and (3) control of the purity of Pt and its alloys for special purposes. J. S. MARSH, SECTION EDITOR

Studying Gear Steels with the Microscope. John T. Horat. *Machine Design*, Vol. 7, Dec. 1935, pages 29-31. Heat treatment and resulting physical properties in relation to microstructure are considered. WH (10)

The Diffusion of Non Metallic Elements in Iron and Steel. Arthur Bramley, Frederick Wardle Haywood, Arthur Thomas Cooper & John Thomas Watts. *Transactions Faraday Society*, Vol. 31, May 1935, pages 707-734. The diffusion of S, O_2, P and the effect of O_2 on diffusion of N_2 were studied. Using Swedish iron 0.03% C, .08% Mn, .008% P, .01% S and tr. Si, and exposing to 0.8-1.0% H_2S in H_2 followed by intermittent exposures to H_2 alone over a period of 40 hours, the following data were obtained:

Temp. °C	Temp. ° Abs.	Diffusivity of S K x 10^{10}
950	1223	3
1000	1273	5.5
1050	1323	7.0
1100	1373	10.0
1150	1423	13.0

The data do not fit perfectly the equation $\log K = \frac{A}{T} + B$. Using steels with 0.125%, 0.410%, and 0.965% C, 0.050%, 0.080% and 0.180% S, (Mn, Si and P being fairly uniform) the rate of diffusion of S in steel was found to be greatly reduced by C. 50 points increase in C halved the diffusion rate. The diffusion of S in Fe and steel follows Fick's law. The diffusivity constants are less than 1/300 that of C and N_2. The presence of S depresses markedly the diffusion of C in metal. The diffusion of O_2 was not easy to follow. Using deoxidation data from Armco Fe the diffusivity constant of O_2 in Fe was found to be 7.5×10^{-10} at 1000° C. The presence of dissolved Fe oxide has a slight but definite lowering effect on the rate of diffusion of C in steel. This effect is much less than the effect due to S. The quantity of nitride formed and its rate of diffusion into metal is increased by the presence of a limited amount of O_2 in the nitriding atmosphere and the presence of Fe oxide in the steel. The optimum effect is obtained if 2% O_2 is in the nitriding mixture of $N_2 + NH_3$. If preliminary oxidation of steel has not formed Fe oxide on surface, nitriding is increased, but if the slightest trace of microscopic crystals of Fe oxide is on the surface the nitriding is completely inhibited. The rate of diffusion of N has been found to depend on the concentration of dissolved oxide, the diffusivity constant increasing from 1.8×10^{-8} for deoxidized Swedish iron to 3.5×10^{-8} if the iron has been previously annealed at 1000° C. for 200 hours. 22 references. PRK (10)

New Diagrams for the Systems Pb-Tl and Pb-Tl-Cd. Correction (Neue Zustandschaubilder für die Systeme Pb-Tl und Pb-Tl-Cd. Ergänzung). Ernst Jänecke. *Zeitschrift für Metallkunde*, Vol. 27, June 1935, page 141. New experimental work of A. ölander indicates that the two-phase field between the Pb and $PbTl_2$ solid solutions should extend from 49 to 55% Pb, and that the $PbTl_2$ field should end at about 10% Pb on the Tl side. No changes are required for the Pb-Tl-Cd system. GD (10)

Superstructure Phenomena in Nickel-arsenide alloys (Überstrukturerscheinungen in Nickel-Arsen-Legierungen). F. Laves. *Fortschritte der Mineralogie, Kristallographie & Petrographie*, Vol. 19, Sect. I, 1935, pages 33-37. The mechanism of the formation of super- and "under-structures" is theoretically discussed and rotating X-ray photographs of Ni_3As_2 are presented. EF (10)

Constitution of Alloys of Copper, Aluminum and Silicon (1). Three Equilibrium Diagrams of Binary Alloys, Copper-aluminium, Aluminium-silicon and Copper-silicon systems. Chiuyo Hisatsune. *Tetsu-to-Hagane*, Vol. 21, Sept. 25, 1935, pages 726-742. In Japanese. By means of differential thermal analysis, electric resistance measurement, and microscopic examination, the diagram of the Cu-Al system was investigated, and a new diagram has been proposed. The liquidus of this system consists of 8 branches corresponding to the crystallization of phases, α, β, γ_1, ϵ_1, ϵ_2, η_1, θ and K. In this system the following nonvariant reactions take place.

Reactions	Temp. °C.	Ranges of composition (% Cu)
Melt $\rightleftarrows \alpha + \beta$,	1037	92.4 ~ 90.4
Melt $+ \beta \rightleftarrows \gamma_1$,	1020	83.7 ~ 82.0
Melt $+ \gamma_1 \rightleftarrows \epsilon_1$,	958	80.0 ~ 77.6
Melt $+ \epsilon_1 \rightleftarrows \epsilon_2$,	848	77.5 ~ 72.0
Melt $+ \epsilon_2 \rightleftarrows \eta_1$,	624	73.0 ~ 57.3
Melt $+ \eta_1 \rightleftarrows \theta$,	591	70.0 ~ 53.5
Melt $\rightleftarrows \theta + \kappa$,	548	52.5 ~ 5.7
$\beta \rightleftarrows \alpha + \gamma_2$,	572	90.3 ~ 84.5
$\gamma_1 \rightleftarrows \beta + \gamma_2$,	780	86.4 ~ 84.5
$\gamma_1 + \epsilon_1 \rightleftarrows \gamma_2$,	873	82.2 ~ 78.9
$\gamma_2 + \epsilon_1 \rightleftarrows \epsilon_2$,	850	79.8 ~ 78.5
$\gamma_2 + \epsilon_2 \rightleftarrows \delta$,	686	79.2 ~ 76.8
$\epsilon_2 \rightleftarrows \delta + \zeta_1$,	560	77.4 ~ 75.7
$\zeta_1 \rightleftarrows \delta + \zeta_2$,	530	77.8 ~ 75.2
$\epsilon_2 + \eta_1 \rightleftarrows \zeta_1$,	590	75.4 ~ 72.2
$\zeta_1 + \eta_1 \rightleftarrows \zeta_2$,	570	74.4 ~ 72.1
$\zeta_2 + \eta_1 \rightleftarrows \eta_2$,	560	73.8 ~ 72.1
$\theta + \eta_1 \rightleftarrows \eta_2$,	563	70.0 ~ 53.7

The transformation, $\gamma_1 \rightleftarrows \gamma_2$, takes place at 780° ~ 873° in the range 84.5-82.0% Cu (determined by Stockdale). ϵ and η phases undergo polymorphic transformations $\epsilon_1 \rightleftarrows \epsilon_2$ and $\eta_1 \rightleftarrows \eta_2$ respectively. The δ and ζ_1 phases are newly found and each of them forms solid solution in some range of composition. The θ phase crystallizes from the melt, and forms a solid solution in a narrow range of composition. Brief considerations on the binary diagrams of Al-Si and Cu-Si systems are given. TS (10)

BJS

The Nature of the Diffusion of Mercury on Tin. T. Alty & A. R. Clark. *Transactions Faraday Society*, Vol. 31, Apr. 1935, pages 648-659. Diffusion of clean Hg in pure Sn melted *in vacuo* was studied. The diffusion consisted of a rapid surface diffusion accompanied by a much slower volume diffusion. The surface diffusion obeyed the ordinary diffusion equations. The variation of the rate of diffusion with temperature obeyed the same laws as of absorbed films. The energy of activation of the mobile atoms on a pure Sn surface was found to be $E_0 = 1920$ Cal./g. atom. The rate of diffusion was dependent on the nature of the medium surrounding the Sn, being faster in water and slower in oil than in air. The diffusion on the surface of Sn amalgam of 8 atomic % Hg was found to have a negative temperature coefficient. PRK (10)

Note on MgZn and $MgZn_5$. L. W. McKeehan. *Zeitschrift für Kristallographie*, Vol. 91, Oct. 1935, pages 501-503. In English. Critical discussion on a previous paper by Tarchisch (See *Metals & Alloys*, Vol. 5, Aug. 1934, page MA 414, R8) and new interpretation of the structure of these intermetallic compounds. EF (10)

Solid Solutions With a Varying Number of Atoms in the Unit Cell. Gunnar Hägg. *Zeitschrift für Kristallographie*, Vol. 91, Aug. 1935, pages 114-122. In English. Copper-zinc Diagram (Beitrag zum Kupfer-Zink-Diagramm) J. Schramm. *Metallwirtschaft,* Vol. 14, Dec. 6, 1935, pages 995-1001; Dec. 20, 1935, pages 1047-1050. A number of disputed points in the Cu-Zn diagram were investigated by thermal and microscopic analysis of samples melted in an evacuated porcelain tube. An improved method for obtaining heating and cooling curves with a mirror galvanometer was used, which produced extremely accurate results. The transformation which takes place at about 900° C. was found to be peritectic α + melt $\rightleftarrows \beta$. The composition of these phases is $\alpha = 67.7\%$ Cu, $\beta = 63.5\%$ Cu and melt = 62.5% Cu. At 834° there is transformation among the phases β, γ, and melt which consists of solidification or melting, melt $\rightleftarrows \gamma$. The composition of β is 43.5% Cu, and γ and melt 40.25% Cu. The point H in the diagram does not correspond to the compound Cu_2Zn_3, as claimed by Bauer and Hansen, as the alloy solidifies over a temperature interval. The point W on the peritectic line UVW has the composition 1.70% Cu. The improved Cu-Zn diagram is given. 29 references. CEM (10)

On Naming the Aggregate Constituents of Steel. J. R. Vilella, G. E. Guellich & E. C. Bain. *Metal Progress,* Vol. 28, Aug. 1935, pages 28-33; *American Society for Metals, Preprint* 3, 1935, 28 pages. Micrographs are employed to illustrate and classify the modes of transformation of austenite and the tempering of martensite in C steel. A simple basis of nomenclature is set forth. "Pearlite" is applied to all lamellar structures formed directly from austenite at comparatively high sub-critical temperatures (about 950° F.). "Martensite" is applied to the constituent resulting from the transformation of austenite at low temperatures (about 300° F.). "Sorbite" is the product of tempering martensite. "Spheroidite" is suggested to designate the more coarsely spheroidized carbide structure. "Troostite" is not used in their nomenclature and a constituent resulting from the transformation of austenite at temperatures between 1000° and 300° F. is not named. Its hardness and coalescence depend upon the temperature of transformation and it is tougher than tempered martensite of the same hardness. It seldom occurs in commercial steel. WLC (10)

A Study of the Molybdenum-carbon System. W. P. Sykes, K. R. Van Horn & C. M. Tucker. *Transactions American Institute of Mining & Metallurgical Engineers,* Vol. 117, 1935, pages 173-189. Includes discussion. See *Metals & Alloys.* Vol. 7, Jan. 1936, page MA 26R/2. (10)

Solubility of Oxygen in Solid Cobalt, and the Upper Transformation Point of the Metal. A. U. Seybolt & C. H. Mathewson. *Transactions American Institute of Mining & Metallurgical Engineers,* Vol. 117. 1935, pages 156-172. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 26L/9. (10)

Origin and Growth of Graphite Nuclei in Solid and Liquid Iron Solutions. H. A. Schwartz & Wolfram Ruff. *Metals Technology, American Institute Mining & Metallurgical Engineers Technical Publication* No. 655, Dec. 1935, 17 pages. The number of nuclei capable of growing into graphite aggregates was determined by observing the number of such aggregates per unit volume of alloy. It was found that the number of nuclei in white Fe capable of growth is a function of the temperature at which germination takes place and also of various melting conditions, including composition of furnace atmosphere. The number of nuclei capable of growth during freezing presents a more difficult problem and was not completely investigated. Some variables of melting practice effective in altering nucleus number in white Fe are shown to have similar effects in gray Fe. A means was devised for evaluating the degree of "sprawliness" of secondary graphite, and a means suggested, though less successful, may be of some value in the same connection for primary graphite. Various theories of nucleation receive attention. 24 references. JLG (10)

Lattice Constants of Five Elements Possessing Hexagonal Structure. E. A. Owen, Llewelyn Pickup & I. O. Roberts. *Zeitschrift für Kristallographie,* Vol. 91, July 1935, pages 70-76. In English. Reports on precision measurements on the following hexagonal elements: Zn, Mg, Ru, Os, and Be. The methods of calculating the parameters are fully described. Purity of metals utilized and previous determinations are given. EF (10)

Crystal Structure of CdSb. Arne Ölander. *Zeitschrift für Kristallographie,* Vol. 91, Sept. 1935, pages 243-247. In English. Rotating-crystal photographs and powder photographs of compound CdSb lead to the following dimensions of the unit cell a = 8.492 A.U.; b = 8.320 A.U.; c = 6.390 A.U. There are 16 atoms per unit cell. The structure of CdSb is probably a severely deformed NaCl type. EF (10)

X-ray Study of Copper-silver Alloys. E. A. Owen & Joseph Rogers. *Metal Industry,* London, Vol. 47, Sept. 13, 1935, page 273. Abstract. See *Metals & Alloys,* Vol. 6, Aug. 1935, page MA 332R/5. HBG (10)

Precision Determination of Lattice Constants. Eric R. Jette & Frank Foote. *Journal of Chemical Physics,* Vol. 3, Sept. 1935, pages 605-616. In Part I the theoretical and experimental conditions which must be satisfied in order to determine lattice constants with a precision of a few parts per 100,000 are discussed with particular application to the symmetrical focussing type of camera. Cohen's method of calculation of lattice constants *(Revue of Scientific Instruments,* Vol. 6, 1935, pages 68-74) for the elimination of "drift" and experimental errors is applied. Methods are developed for the evaluation of standard errors and fiduciary limits of results from a single film and from a set of films. The usefulness of X-ray targets made of alloys rather than pure metals for the purpose of securing a larger number and better distribution of lines is indicated. The influence of the number and Miller indices of diffraction lines on the values of lattice constants in non-cubic systems is shown. The importance of the methods of sample preparation for precision work is emphasized. In Part II precision measurements (in A.U.) on the following 14 metallic elements of high degree of purity are reported: Al: a = 4.04139; Ni: a = 3.51684; Ag: a = 4.07787; Au: a = 4.07042; Si: a = 5.41982; Fe: a = 2.86046; Mo: a = 3.14103; W: a = 3.15837; Mg: A = 3.20300, c = 5.2002; Zn: a = 2.65949, c = 4.93685; Cd: a = 2.97311, c = 5.60694; Sb: a = 4.29957, c = 11.2516; Bi: a = 4.53726, c = 11.8381; Sn: a = 5.81950, c = 3.17500. The fiduciary limits of these lattice constants vary between 2 and 7 parts per hundred thousand and are so chosen that the probability of the correct value lying between the stated limits is 19 out of 20. The densities (25° C.) calculated from the X-ray data are compared with the density values given by the International Critical Tables. EF (10)

X-ray Study of Iron-nickel Alloys. Eric R. Jette & Frank Foote. *Metals Technology,* Jan. 1936, *American Institute Mining & Metallurgical Engineers Technical Publication* No. 670, 14 pages. Alloys studied were vacuum melted from carbonyl Fe and electrolytic Ni. Lattice constants of the γ phase were determined over the range 25 to 100% Ni with high precision. Positive deviations from the additive rule of exceptional magnitude were observed. The maximum lattice constant was found at 39 at. % Ni. From 100 to 43 at. % Ni the lattice constant varied as:

$$a_o = 3.64033 - 0.0012379 \text{ (at. \% Ni)}$$

It decreases sharply from its maximum value and from 0 to 20% Ni it extrapolates in a linear manner to Ohman's value for pure γ Fe. The α phase up to 5% Ni was also studied and a marked positive deviation found. A limited number of experiments were made to determine the 2-phase region, but the results give highly tentative limits. No evidence of compound formation or superstructures was found. 18 references. JLG (10)

The Lattice Constants of Beryllium. E. A. Owen & Llewelyn Pickup. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Vol. 20, Dec. 1935, pages 1155-1158. On account of discrepancies of previous determinations, a redetermination of the lattice constants of Be was made with the result that $a_o = 2.2810_5$ A.U. and $c_o = 3.5571_4$ A.U., therefore $c_o/a_o = 1.5682$. The source of previous errors is discussed. Ha (10)

Crystal Structure of $AuBe_5$ and $PdBe_5$ and Its Relation to the Cubic AB_2 Structure (Die Kristallstruktur des $AuBe_5$ und $PdBe_5$ und ihre Beziehung zur kubischen AB_2-Struktur) Lore Misch. *Metallwirtschaft,* Vol. 14, Nov. 8, 1935, pages 897-899. The intermetallic compounds $AuBe_5$ and $PdBe_5$ were prepared by melting in an electric furnace, and were examined by X-rays. Both have a face-centered-cubic lattice with 24 atoms in the elementary cell. The lattice constant for $AuBe_5$ is 6.085 A.U. and for $PdBe_5$ 5.982 A.U. The lattice structure is not quite the same as the typical cubic AB_2 structure, such as $MgCu_2$, but corresponds to that of ZnS. CEM (10)

Arsenic-Lead Alloys (Die Arsen-Bleilegierungen) O. Bauer & W. Tonn. *Zeitschrift für Metallkunde,* Vol. 27, Aug. 1935, pages 183-187. The equilibrium diagram to 30% As was redetermined by cooling curves taken on 100 gram melts; a eutectic at 2.6% As and 290° was found. Powder photograms show that the phase separating beyond the eutectic is nearly pure As. Hardness measurements on alloys homogenized at 280° and then quenched from various temperatures indicate a solubility of 0.045 to 0.05% As at the eutectic temperature, which decreases to less than 0.01% at 20°. The As-rich solid solution is appreciably harder. The hardness of alloys quenched from 280° diminished markedly at 20° in six weeks. The specific gravity decreases linearly from that of pure Pb (11.3) to 10.778 at 5% As. In both chill cast and slowly cooled samples no segregation was found up to 2.5% As, but with greater additions As tends to concentrate at the top. Piping was a minimum at the eutectic composition. Repeated remelting at 550° showed small losses of As. Shrinkage was diminished by additions of up to 0.1% As. Corrosion in distilled water containing 70 mg. CO_2/l. was inhibited by the formation of a protective coating which was not formed if only 2 mg. CO_2/l. was present, the presence of As having no apparent effect. These As alloys seem to have no advantage over the usual bearing and type metals. GD (10)

X-ray Analysis of Lithium-zinc Alloys (Röntgenanalyse der Lithium-Zink Legierungen) E. Zintl & A. Schneider. *Zeitschrift für Elektrochemie,* Vol. 41, Nov. 1935, pages 764-767. Debye-Scherrer photograms were made of Li-Zn alloys at room temperature with filtered Cu-K radiation. Among the interference lines of the 1.9 at. % Li alloy were those of Zn solid solution and of β' phase. At 10.5 at. % Li, only β' interferences appear. At 28 % Li, only γ' phase exists. At 32 and 39 % Li, lines of $LiZn_2$ are relatively weak, fading into those of γ' and δ' phases, respectively. δ'-phase exists at 42, 46, and 49 % Li. The interference lines of LiZn appear with increasing intensity for these latter alloys. According to the equilibrium diagram the alloys above 50 % Li should contain free Li but this could not be proved because of the low scattering power of the Li atom. Interference lines of LiZn are found up to 80 % Li. From powder photograms of the 10.5 % Li alloy the structure of the β'-phase was found to be hexagonal: c/a = 1.57, a = 2.782 and c = 4.385 A.U. There are 2 atoms per unit cell. The atomic species are arranged statistically. This is checked by intensity measurements and calculations of lattice parameter using Goldschmidt's atomic-radii values and assuming a coordination number of 12. The structure of the phase at 28 % Li is hexagonal, c/a = 0.57, a = 4.362 and c = 2.510 A.U. These dimensions refer to a pseudo-cell in which the 2 Zn atoms are at 000 and 1/3, 2/3, 1/2. Line intensities indicate the true unit cell to be 4 times larger than this pseudo-cell. For the true unit cell then either $c' = 4c$, and $a' = a$, or $c' = c$ and $a' = 2a$. HAS (10)

Structure of Platinum-Thallium Alloys (Struktur der Platin-Thallium Legierungen) E. Zintl & A. Harder. *Zeitschrift für Elektrochemie,* Vol. 41, Nov. 1935, pages 767-771. In this system only one intermediate type of crystal, PtTl occurs. Solubility of Pt in Tl could not be detected from the powder diagrams. Tl dissolves in Pt, expanding the lattice by 1.5%. Alloys above 50 atomic % Tl contain free Tl. Rotating crystal and Weisenberg goniometer photograms were made of single crystals of PtTl. Data from these and from powder photograms permitted a determination of the structure: hexagonal, a = 5.605 A.U., c = 4.639 A.U. There are 3 atoms of Pt and 3 of Tl per cell. The position of the 6 atoms (each of about the same scattering power) are 000, ½ ½ 0, ½ 00, 0½0, 1/3 2/3 1/2, 2/3 1/3 1/2. Interatomic distances are: atoms at 000 have 6 neighbors at 2.80 A.U.; atoms at ½00, 0½0, ½½0 have 6 neighbors at 2.80 A.U. and 4 neighbors at 2.83 A.U.; and atoms at 1/3 2/3 1/2 and 2/3 1/3 1/2 have 6 neighbors at 2.83 A.U. Pt does not form with Tl any structure of the nickel-arsenide type. HAS (10)

Formation of Solid Solution with Tin Monoxide (Über Mischkristallbildung mit Zinnmonoxyd). Erich Hayek. *Sitzungsberichte der Akademie der Wissenschaften in Wien, Mathematisch-Naturwissenschaftliche Klasse, Abt. II b, Chemie,* Vol. 144, No. 7, 1935, pages 329-332. Solid solutions of SnO with oxides of other bivalent metals were prepared. Whereas solid solutions with Pb, Mn, Fe, Zn, Cd, and Ca could be obtained, Co, Ni, Mg, Sr, and Ba did not enter the SnO lattice. The preparations made exhibit characteristic colors. Their homogeneity was proved by X-rays. EF (10)

OFHC
REG. U.S. PAT. OFF.

OXYGEN-FREE HIGH CONDUCTIVITY

A Superior Copper for All Purposes

OFHC Copper conforms to the A.S.T.M. Specification for electrolytic copper wirebars, cakes, etc., B5-27 with regard to metal content and resistivity, and is free from cuprous oxide.

OFHC Copper is characterized by its freedom from casting defects and its bar-for-bar uniformity. Its freedom from oxygen results in great ductility and toughness as evidenced by its high reduction of area and resistance to impact.

OFHC Copper withstands more working in hard condition when tensile strength is greatest, making it especially suited for products subjected to severe fabricating or service conditions.

Copies of a schedule of weights and dimensions of **OFHC** wirebars, cakes and billets, and a booklet containing technical information will be gladly furnished upon request.

11. PROPERTIES OF METALS AND ALLOYS

The Structure of Metal Surfaces. L. L. Bircumshaw. *Metal Treatment,* Vol. 1, Autumn 1935, pages 149-151. A review of recent work. Electron diffraction methods show oxide films to have a structure oriented in respect to the metal surface, and have verified the existence of the amorphous Beilby layer on a polished surface. 8 references. JCC (11)

Dynamic Elasticity of Metals (Elasticité dynamique des métaux) A. Leblanc. *Métaux,* Vol. 10, Sept. 1935, pages 209-213. The elastic deformation which is produced in a metal subjected to dynamic forces is given the name of dynamic elasticity. (1) Elastic deformation by impact is given by $\epsilon = 1000\ E^2/2M = 500E^2/M$. Where ϵ is the absorption capacity of impact work per cubic decimeter of metal, M is the coefficient of elasticity longitudinal of the metal. E is the elastic limit of the metal, all terms expressed in kg./mm.^{2} GTM (11)

The Vapor Pressures of Metals (Ueber Metalldampfdrucke) A. Eucken. *Metallwirtschaft,* Vol. 15, Jan. 10, 1936, pages 27-32; Jan. 17, 1936, pages 63-68. A critical review of existing data, made necessary by the many discrepancies recorded. A consideration of experimental methods indicates that direct manometric measurements under equilibrium conditions are valid for temperatures below 1400° C. The dynamic methods all introduce an uncertain error when reduced to equilibrium conditions. Methods depending upon the determination of the boiling point of the metal for various external pressures are all uncertain due to difficulty in measuring the boiling temperature. Kinetic methods such as that of Knudsen which measures the rate of effusion through a jet into a vacuum, or Langmuir's observations of rates of vaporization from heated wires are generally better. Even when data are correct over a small range, direct extrapolation is dangerous. However, by applying thermodynamic equations combined with data on specific heats and heats of vaporization, better vapor pressure curves may be drawn. The data required for these equations are discussed critically and the best values tabulated for 29 important metals, along with the temperature ranges over which the formula may be applied safely. GD (11)

A Comparison of Corrosion-Resistant Steel (18:8) and Aluminum Alloy (24ST). J. E. Sullivan. *National Advisory Committee for Aeronautics, Technical Note* No. 560, Mar. 1936, 11 pages mimeographed. The 2 metals chiefly considered for aircraft construction are compared as to suitability for various types of applications. Each has advantages in certain types of service, but the author considers that 18:8, given the desired properties by cold-working, is not so uniform, nor its properties so capable of accurate determination, as the Al alloy. High tensile steel, given its properties by heat-treatment rather than by cold working is considered to have an advantage over 18:8 even though it may require protection against corrosion. For tie-rods, for example, heat-treated 16% Cr, 1% Ni is considered to have possibilities. The vastly superior impact resistance of 18:8 shown on a notched bar test is not considered conclusive as regards the engineering usefulness, since the ability to resist injury when subjected to a suddenly applied load at the elastic range is of greater importance than the work required for actual fracture. Stainless steel ribs in airplanes were found considerably corroded by salt water in 182 hours of flight time. In inaccessible locations anodically treated Al, painted, is held to be more satisfactory in corrosion-resistance than stainless. HWG (11)

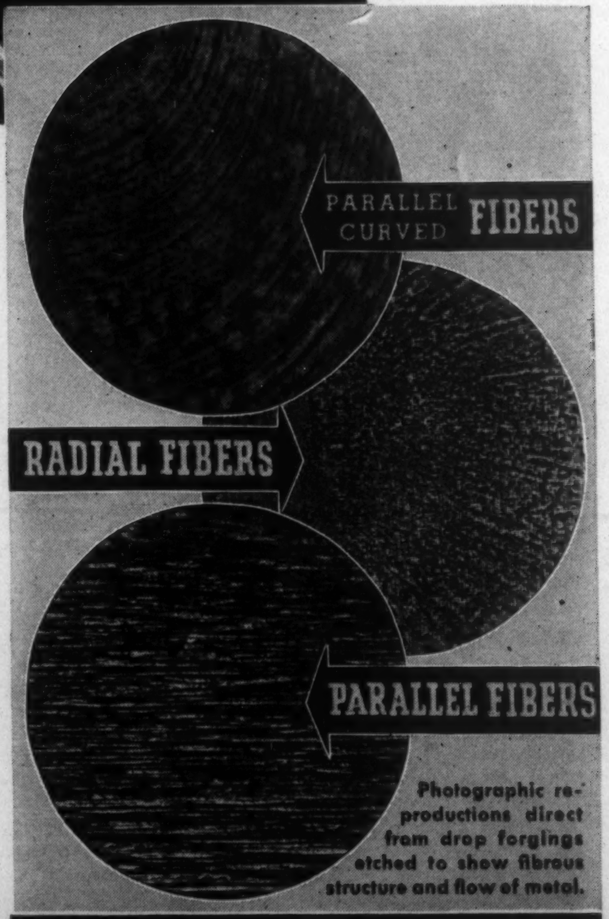
On the Theory of Surface Tension of Liquid Metals. D. V. Gogate & Duleh Sinha Kothari. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Vol. 20, Dec. 1935, pages 1136-1144. The relation of surface tension and total surface energy was theoretically investigated and an electron theory of surface tension of liquid metals is developed. The agreement between observed and calculated values is satisfactory. The surface tension of liquid metals is very much greater than that of other substances; numerical values are given in tables and curves. Ha (11)

Gases in Metals. C. J. Smithells. *Metal Treatment,* Vol. 1, Winter 1935, pages 165-171. Stresses the relation between adsorption, diffusion, and solubility phenomena exhibited by gases in metals. Present knowledge of adsorption and diffusion is well summarized, typical curves being included and diffusion factors for all systems so far investigated tabulated. 6 references. JCC (11)

Increase of Deformability and Decrease of Cleavage with Rising Temperatures (Zum Wachsen der Verformbarkeit und zum Abnehem der Spaltbarkeit mit zunehmender Temperatur) G. Tammann & W. Müller. *Zeitschrift für Metallkunde,* Vol. 27, Aug. 1935, pages 187-189. The general applicability of the title is demonstrated by means of pressure figures and scratches on cleavage faces of Zn, Bi, and Sb, and on picked orientations of α Fe. It is shown that the transition is quite sharp, cleavage disappearing at about 20° in Zn, 150° in Bi, and 300° in Sb. These conclusions are checked by bend tests on Sb and Bi at various temperatures. The pressure figures on Fe confirm cleavage on cube planes. GD (11)

Modulus of Elasticity of Materials for Small Stresses. R. H. Evans & R. H. Wood. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Vol. 21, Jan. 1936, pages 65-80. In order to elucidate the mechanism of creep experiments were made concerning the elasticity of metals and building materials for small stresses. The tests show that as the range of the applied stress is decreased the modulus of elasticity (Young's) increases which seems to indicate that the strain approaches that due to the elastic distortion of the crystals. A theory is developed which gives an explanation for the rapid changes in the value of the modulus near zero stress in both tension and compression. The tests were made with a cast Fe column and are described, together with the instruments used, in detail. 11 references. Ha (11)

In FORGINGS . . . structural UNIFORMITY is an ACTUALITY!



Photographic reproductions direct from drop forgings etched to show fibrous structure and flow of metal.

EMBODIED IN MILLIONS OF FIBERS—

fibers formed and compacted by rolling and hammering (directional working) the steel which unvaryingly responds to every operation of the forging process.

* * * *

In forgings a practical combination of structural and dimensional uniformity is obtained. Unvarying duplication of such attributes as strength, stamina, and flexibility is achieved by the forging process. Kneaded fibers of steel, an exclusive characteristic of forgings, embody sound qualities which survive the shocks and strains of gruelling service. Forgings of a like size and shape possess these qualities in precisely the same degree. Avoid risks arising from structural variations in the parts you use. Specify forgings . . . Write for booklet.

Gallium and Its Compounds. *Chemical Trade Journal & Chemical Engineer,* Vol. 96, Feb. 21, 1935, page 131. From *Bulletin of the Electrochemical Society.* Summary of method of production, properties of the metal, salts, and alloys. MS (11a)

Endurance Limit of Black-Heart Malleable Iron. E. G. MAHIN & J. W. HAMILTON. *Transactions American Foundrymen's Association,* Vol. 6, Dec. 1935, pages 41-47. A blackheart malleable Fe was used in this study with the composition: Si 1.00%, C 2.44%, Mn 0.31%, S 0.072%, and P 0.168%. A determination of the endurance limit was made. Specimens were of the Farmer type, tested in a transverse rotating beam machine. An endurance limit of slightly higher than 30,500 lbs./in.^{2} was found which is somewhat higher than the few tests already on record. A brief discussion of the form of, and the possible influence of, graphite nodules is included. CEJ (11a)

Carbides of Refractory Metals. G. A. MEERSON. *Redkie Metallui,* Vol. 4, July-Aug. 1935, pages 6-20. In Russian. A mixture of TiO_2 and C was heated to a temperature of 1200° to 3000° C. The TiC obtained had a cubic lattice with a parameter of 4.26-4.31 A.U. In most cases the combined C content was much less than the theoretical; only at a very high temperature was the theoretical approached. The TiC was mixed with WC and Co, pressed, and sintered at 1500° C. The alloy obtained had a hardness of 87-90 Rockwell "C" and gave good results in cutting tests. Mixtures of W and Ti carbides were also prepared by heating finely ground W, TiO_2, and C. TiC forms readily and at a lower temperature in the presence of W. HWR (11a)

The Magnesium-copper Alloys. Part V.—The Copper-rich Alloys. W. R. D. JONES. *Journal Institute of Metals,* Vol. 58, Jan. 1936, pages 41-48 (Advance Copy No. 723). Alloys containing as much as 6% Mg were made. Great difficulty was encountered in obtaining good castings because the Mg tended to oxidize and the dross to remain with the solid alloy. Up to 2 or 3% Mg increases the strength of Cu but reduces ductility to a low value. At 4.25% Mg alloys are very brittle and break in the tensile test with no elongation. Most of the alloys cracked when rolled, but alloys with 0.71 and 1.42% Mg were rolled into rods. There is not much possibility that the Cu-rich Cu-Mg alloys will be useful. JLG (11a)

Transversely Loaded Framework Members. N. J. HOFF. *Journal Royal Aeronautical Society,* Vol. 39, Aug. 1935, pages 718-749. Develops mathematical formulae for computing the strength of aircraft framework, avoiding the usual assumption that members are freely pinned. Tests made on experimental constructions corroborated theoretical deductions. FPP (11a)

Metals Used in Die Casting. CHAS. H. HUGHES. *Machinery,* N. Y., Vol. 42, Mar. 1936, pages 446-449. Composition and characteristics of alloys in general use for the production of die castings are described. Al die casting alloys possess the advantage of comparatively high tensile strength, light weight, resistance to corrosion, ability to take a good polish and to hold it under normal atmospheric conditions. Cu base alloys have superior qualities as regards strength, impact value, and elongation, and are not affected by many chemicals. Mg base alloys are about 2/3 as heavy as Al and 1/5 as heavy as brass. Sn lends itself particularly well to die casting because of its low melting point; Sn alloys are used for die casting soda-fountain appliances, parts of dairy machinery and articles that must be immune to action of acids from food products. Ha (11a)

Contribution to the Surface Chemistry of Tin (Beiträge zur Oberflächenchemie des Zinns) ARTUR KUTZELNIGG. *Zeitschrift für Metallkunde,* Vol. 28, Jan. 1936, page 5. The rate of attack of Sn by $FeCl_3$ solution and HCl is markedly increased by the presence in the metal of as little as 0.01% Sb, while considerable protection against attack is afforded by small quantities of alloyed Bi. The relatively great resistance of high purity Sn to attack is attributed to the formation of a protective oxide layer. FNR (11a)

The Differing Behavior of Cast and Recrystallized Single Crystals of Aluminum of Various Degrees of Purity (Über das verschiedenartige Verhalten von Schmelzfluss und Rekristallisations-Einkristallen aus Aluminium verschiedenen Reinheitsgrades) F. GISEN. *Zeitschrift für Metallkunde,* Vol. 27, Nov. 1935, pages 256-261. Recrystallized single crystals of Al are shown to have a critical shear strength which decreases with increasing purity of the metal, while cast single crystals exhibit a gradually increasing plastic response to increasing shearing stresses. Cast crystals were made from 99.5, 99.8, 99.87 and 99.998% Al by the progressive freezing method and some of the crystals so made were subsequently caused to recrystallize into new single crystals by the strain-annealing method. The specimens were loaded in tension and the resulting decreases in diameter were plotted against the load, giving curves composed of 2 straight lines meeting at a sharp critical point in the case of the recrystallized material and single curves of gradually decreasing slope in that of the cast crystals. An effort is made to explain this difference in behavior by the demonstration of the existence of a mosaic structure in the recrystallized specimens. The plastic response to shearing stresses occurs at about 75 g./mm.^{2} in the 99.998% Al recrystallized material and below 20 g./mm.^{2} in similar cast crystals. 27 references. FNR (11a)

The Hydrogen Peroxide Theory of Electrolytic Oxidation and the Influence of the Electrode Surface on Anodic Processes. S. GLASSTONE & A. HICKLING. *Transactions Faraday Society,* Vol. 31, Dec. 1935, pages 1656-1660. Anodic overvoltages were determined on Pt, Au, PbO_2, C and Ni. Overvoltages cannot be correlated in any simple manner with the efficiencies in the oxidation of acetate, thiosulphate and sulphite ions. It is shown that the formation of H_2O_2 in solutions by the union of hydroxyl radicals is not improbable. No one mechanism is likely to account for all the various types of anodic oxidation reactions. 16 references. PRK (11a)

Construction Steels (Les aciers de construction) L. PERSOZ. *Métaux,* Vol. 10, Oct. 1935, pages 216-242. The present study, of which this is the first part, contains the fundamentals of construction steels. It is a comprehensive survey of physical testing, constitution of steels, heat treatments and classifications of steels. All the common physical testing and examination methods employed in control of construction steels are discussed. GTM (11b)

✓ **Recent Uses of Molybdenum in Ferrous Metallurgy (Les récentes applications du molybdène en sidérurgie)** JEAN COURNOT. *Revue de Métallurgie,* Vol. 32, Nov. 1935, pages 562-576. Long list of steels containing Mo including the most recent types supplemented with detailed description and physical properties. Use of Mo in steel casting and in cast irons fully described. JDG (11b)

Nitrogen in Electric Steel. N. CHUIKO. *Domez,* No. 8, 1935, pages 27-38. In Russian. A comprehensive survey of the literature data on the subject and the theoretical considerations regarding the dissociation of N and its solubility in the metal developed by the author are given. A study of 7 heats made in different furnaces run at a different rate and having dissimilar arcs showed that N increases in the metal in direct proportion to the time of heat, other conditions being equal, up to its saturation point, 0.03-0.04% N. A more rapid N absorption could be observed when the surface of the bath was bare. Absorption speed increases with the tension of the arc and specific capacity of the furnace. The type of the arc, stationary or rotating, does not have any effect. (11b)

Oxygen in Copper. H. J. MILLER. *Metal Treatment,* Vol. 1, Winter 1935, pages 191-194, 201. The amount of O in molten Cu determines the amount of H dissolved and thus the soundness or "pitch" of the resulting ingots. The effect of O content on annealing temperature, tensile properties after varying degrees of reduction, fatigue endurance, and susceptibility to "gassing" is reviewed. 22 references. JCC (11b)

Steel, Report of Committee A-1. H. H. MORGAN, Chairman. *Proceedings American Society for Testing Materials,* Vol. 35, Part I, 1935, pages 60-69. Progress report on Tentative and Standard Specifications and revisions. VVK (11b)

✓ **Copper-Molybdenum Steel.** *Industry & Welding,* Vol. 8, Jan. 1936, pages 57-59. Cu-Mo steel as corrosion-resisting material is described in general. The average composition is usually: C 0.045%, Mn 0.45%, S 0.013%, P 0.014%, Si 0.01%, Cu 0.3%, Mo 0.05%. Mo forms so solid a solution with ferrite that it is impossible to detect its presence by micrographic methods; it gives a fine, close-grained structure to the Cu-Mo steel, and increases resistance to corrosion, ductility and toughness, impact strength, resistance to oxidation at elevated temperatures, and the ratio of elastic limit to tensile strength is very high. Corrosion and physical tests are described. Ha (11b)

Iron-Carbon-Beryllium Alloys (Alliages Fer-Carbone-Glucinium) M. BALLAY. *Usine,* Vol. 44, Dec. 19, 1935, page 27. Fe alloys with 3-4.45% C and 0-4% Be (besides 0.25% Mn, 0.25% Si, 0.02% S, 0.05% P) were studied. Solidification took place in the metastable cementite system without graphite formation. With Be contents of 1.2-1.7%, the apparent quantity of cementite bound to the existence of complex carbides of Fe and Be was increased quite considerably. A Be carbide of the form Be_2C was found at higher Be contents. The hardness after quenching from 950° C. depends on the Be content; compared with the hardness as cast the following figures were found:

		hardness (Vickers 50 kg.)		
% C	% Be	after casting	after quenching at 950° C.	Structure of cast state
3.15	0	407	608	pearlite + cementite
3.08	0.31	426	657	pearlite + cementite + little graphite
3.16	0.65	325	604	pearlite + cementite + graphite
3.14	1.43	740	906	pearlite + complex cementite
3.20	2.15	543	849	pearlite + complex cementite + little Be_2C
3.15	2.80	493	836	pearlite + secondary cementite + Be_2C
3.30	3.88	443	691	pearlite + Be_2C + very little secondary cementite

A maximum hardness of 935 was found for an alloy with 4.32% C and 1.7% Be. The A_c transformation point of Fe-C alloys is little influenced by addition of Be. Ha (11b)

Graphitization of Cast Iron (Note au Sujet de la Graphitisation des Fontes) A. LE THOMAS. *Revue Universelle des Mines,* Vol. 11, Dec. 1935, pages 553-554. Tests made by the author agree with the results published previously by Portevin (*Comptes Rendus,* Vol. 189, 1929, page 759); 300° C. must be assumed as the practical temperature below which castings do not undergo any further measurable change by slow graphitization. 11 references. Ha (11b)

B3S ✓ **Heat Resistant Cast Irons (Fontes pour Applications a Chaud)** R. LEMOINE. *Bulletin de l'Association Technique de Fonderie,* Vol. 9, Oct. 1935, pages 339-340. Paper presented at the General Meeting of French Foundrymen. Growth of cast Fe is caused by graphitization, formation of fissures, and formation of compounds. Heat resistant cast irons are divided into 2 classes, pearlitic and non-pearlitic. The pearlitic class includes: (a) cast Fe with Si content as low as possible for gray cast Fe; (b) low Si cast Fe which is gray because of heated molds and slow cooling; (c) low Si irons cast white and annealed; (d) low C cast Fe with low Cr content; (e) cast Fe which would normally be white, but is cast gray because of stream or ladle additions. The non-pearlitic class consists of: (a) white cast Fe with low Si and high Cr contents; (b) ferritic Fe with high Si or high Al content; (c) cast Fe of stable austenitic structure; (d) solid solution irons with very high Cr content. WHS (11b)

SOME NOTES ON BETHLEHEM ALLOY STEELS

VII-Silico-Manganese Steels

Silicon is a powerful deoxidizing agent, and manganese to a lesser degree behaves in the same manner. Manganese also exerts beneficial effects on the physical properties of heat-treated steel. Silicon increases strength. The balanced combination of both elements produces a steel of unusually high strength and one with sufficient ductility for the services to which it is adapted.

The silico-manganese steels are grouped under the S. A. E. 92xx Series and contain about 2.00 per cent silicon and 0.80 per cent manganese. The carbon content varies in accepted ranges from 0.48 to 0.67 per cent, depending on the application and the heat-treatment requirements.

One of the most important applications of silico-manganese steels is for springs, both in the railway and automotive fields. Bethlehem pioneered the application of silico-manganese steel to springs more than 25 years ago. In the years that have elapsed since its introduction, continuous effort has been put forth to bring out the full latent possibilities of this steel as spring material.

A spring dissipates energy, mainly through internal strain friction. If this internal strain is within the elastic limit of the material, it will ordinarily not cause fatigue—provided there is sufficient time between flexures to permit the metal to recover. Severe stresses, though within the elastic limit, if occurring in quick succession are to some extent cumulative in their effects on the steel. Fatigue may follow. Proper methods of manufacture and effective heat treatment insure maximum endurance.

As Bethlehem makes silico-manganese steels for springs, the surface is carefully processed at all stages to avoid imperfections that might provide a starting place for fatigue. Special care is exercised in rolling to obtain cold-shearing qualities and, in the case of flat sections, punching and trimming qualities. The uniformity of the structure is controlled with extreme accuracy to insure both high inherent fatigue resistance and uniform heat-treating characteristics.

Although silico-manganese steels have their principal use for springs, they have also been successfully used for chisels, drift pins, punches, digging bars, shear blades, mine bits and pulp-beater bars. They respond readily to oil quenching and, when drawn to the correct temperature, possess, in addition to the strength required for springs, excellent toughness and resistance to shock.

Heat Resisting Cast Irons. E. Morgan. *Proceedings Institute of British Foundrymen*, Vol. 26, 1932-1933, pages 148-174. See *Metals & Alloys*, Vol. 5, Apr. 1934, page MA 160. CEJ (12)

Expansion of Light Metals for the Pistons of Combustion Motors at the Operating Temperatures (Dilatazione delle Leghe leggiere per Stantuffi di Motori a Scoppio alle Temperature di Funzionamento) C. A. Maresca. *Industria Meccanica*, Vol. 18, Jan. 1936, pages 1-5. The expansion coefficients of 10 of the most used Al alloys were measured and are given, together with the nature of heat treatment and Brinell hardness of the material, in a table for the interval of +20° to +275° C. A modified method of measuring the temperatures with the Chevenard instrument is described. Ha (12)

have

Notched-Bar Toughness of Fusion Welds at Low and High Temperatures. Wilhelm Kleinefenn. *Iron & Steel Institute, Carnegie Scholarship Memoirs*, Vol. 24, 1935, pages 87-102. The position of the steep portion of an impact-temperature curve relative to temperature is taken as a criterion for indicating whether or not the welds are satisfactory under the conditions of the tests. The steep portion of this curve is lowest for welds made using covered electrodes, and highest for welds made using bare-wire electrodes. Normalizing for half an hour at 920° C. gives rise to a movement of the steep portion of the curve toward lower temperatures in the case of autogenous welded specimens but has little effect on the electrically welded ones. By use of alloyed welding rods the notch toughness of welds is increased, particularly at high temperatures. Specimens welded by the autogenous method or by the electric arc using bare-wire electrodes show a very coarse grain when fractured. If, however, covered electrodes are used the fractured specimens have a much finer grain. Better notch toughness values are obtained by use of covered alloy electrodes in the case of autogenous and direct current welding. This, the author believes, is due to the fact that Ni reduces the amount of gas absorption in the weld. Bare wire electrodes containing Ni do not have this advantage in the case of direct current welding because the adsorption of gas is too great. Unalloyed electrodes used in the tests contained 0.08% to 0.10% C and alloyed electrodes 0.05% to 0.15% C with 2% to 3.5% Ni. The parent metal welded in the tests was a commercial steel. 16 references. CW (12)

The Properties of Metals at Elevated Temperatures. C. L. Clark & A. E. White. *Engineering Research Bulletin* No. 27, *University of Michigan*, March 1936, 100 pages. Price $1.00.

Investigations carried on for commercial interests and previously reported in a score of papers by these authors are here collected into a connected running account. The pamphlet is unique in its field in that it cites no literature and includes no data from sources other than the work of the authors. Even the University of Michigan work on torsional creep, carried out in another department, is excluded. The question of variation of methods, used by different investigators, therefore, does not arise, but with such a title it seems odd that no reference was made to the experimental work of the Bureau of Standards, of the National Physical Laboratory, of Norton for Babcock and Wilcox at Massachusetts Institute of Technology, of the General Electric Company, the Midvale Company, or the Joint Committee on the Effect of Temperature on the Properties of Metals.

Though the authors have thus chosen to consider only their own data, there is a lot of data, used more to establish the general principles the authors desire to stress, than for its own sake, and in presentation of these data, much pertinent information that the reader needs has not been included so that the originals need to be consulted. This pamphlet is thus chiefly valuable for the general picture it presents. While it is chiefly concerned with creep, it brings out clearly that creep resistance is only one of several properties that the engineer must evaluate in selecting a metal for high temperature service.

One oddity in a presentation normally conscientious and scientific is the presentation of one plot of data with the alloys described by trade names only, although in a previous discussion (*Metal Progress*, Oct. 1934, page 54), some of the same data were published with some information as to composition. H. W. Gillett (12) -B-

13. CORROSION AND WEAR

V. V. KENDALL, SECTION EDITOR

A Laboratory Study of the Atmospheric Corrosion of Metals. Part II—Iron: The Primary Oxide Film. Part III—The Secondary Product or Rust (Influence of Sulphur Dioxide, Carbon Dioxide, and Suspended Particles on the Rusting of Iron) W. H. J. Vernon. *Transactions Faraday Society*, Vol. 31, Dec. 1935, pages 1668-1700. Marked differences in the properties of the oxide film on Fe were observed according to whether the film was produced above or below a critical temperature of very nearly 200° C. At a higher temperature a parabolic relation between oxidation and time was closely followed. The colors produced are consistent with interference of light in a continuous transparent sheath. At temperatures below the transition point, there is a marked deviation from the quadratic parabola. The relationship between film thickness and color is no longer obtained. The ill-defined colors that ultimately appear suggest diffraction in a granular type of film. In purified air of high relative humidity, the rusting of mild steel is greatly reduced owing to the strengthening of the primary film in the early stages if the higher humidities are approached gradually from zero. In the presence of traces of SO_2, when the relative humidity is gradually increased from zero, the metal remains bright. At approximately 50% relative humidity, which is considered the primary critical humidity, there is a marked increase in the weight increment followed at a little higher humidity by the appearance of rust. At approximately 80% relative humidity, which is known as the secondary critical humidity, there is still more pronounced increase in the rate of attack and the specimen becomes rapidly covered with rust. The primary critical humidity marks the requisite relationship between water vapor, O_2 and SO_2 for rusting to commence. The secondary critical humidity depends only on the properties of the initially formed rust and is probably associated with its gel structure and is independent of the presence of SO_2. The influence of suspended solid particles depended on whether they were (1) intrinsically active, as $(NH_4)_2SO_4$; (2) neutral, capable of adsorbing active gases as charcoal; (3) neutral, with negligible capacity for adsorption, as silica. CO_2 had a marked repressive effect on the corrosion of iron under all conditions investigated. 30 references. PRK (13)

Tantalum as a Constructional Material. *Chemical Trade Journal & Chemical Engineer*, Vol. 98, Mar. 6, 1936, page 190. Ta offers excellent resistance to acid corrosion particularly when subjected to combined action of acid and air. It has given good service in direct-fired stills, when proper precautions are observed; storage tanks; and acid vaporizer pipes in chlorination and sulphonation of oils. In fabrication, Ta sheet is similar to Ni. MS (13)

The Influence of Light on Electrode Potential and Corrosion Phenomena of Certain Non-ferrous Metals. C. O. Bannister & R. Rigby. *Journal Institute of Metals*, Vol. 58, Feb. 1936, pages 91-108 (Advance Copy No. 726). Previous work on the influence of light on the corrosion of ferrous and non-ferrous metals is reviewed. A simple apparatus is described for the examination of effects of light on Zn, Pb and other metals under corroding conditions in conjunction with a continuous record of changes of e.m.f. made by a thread recorder. The influence of light was considerable in the case of Pb and Zn, but only in the presence of O, the aerated and illuminated electrode becoming more markedly cathodic. A more elaborate apparatus is then described by which perfect control of O supply is obtained. A very marked response to illumination was found in the case of Zn and Al in the presence of O. The maximum effect was obtained with light in the violet and near ultraviolet region. It is suggested that the mechanism of the phenomenon is the catalysis of the formation of the protective oxide films. 28 references. JLG (13)

The Corrosion Problem in Steel. A. McCance. *Iron & Coal Trades Review*, Vol. 132, Feb. 28, 1936, pages 399-400; Mar. 6, 1936, pages 448-450. The chemical composition of rust has lately been definitely confirmed by the electron-diffraction method to be $FeO(OH)$, regardless of the color of the rust. Heating to 200° C. converts the rust into the magnetic form Fe_2O_3. The various reactions going on in air are described. When immersed in H_2O the rate of rusting is controlled by the amount of O dissolved in the H_2O, and by the rate at which this O can be replenished as it is used up. These conditions are investigated in their dependence on composition of steel and test results shown in curves. The addition of Cu is of benefit in atmospheric corrosion but not in water corrosion. Formation and value of protective films on various steels are discussed, and the inhibiting effect of Na bichromate on corrosion in Na brine shown in a curve. Attention is called to the fact that the number of cases of corrosion in seagoing vessels is on the increase since the war. The explanation given ascribes this increase to secondary causes such as change in practice of shipbuilding but not to any fundamental deterioration in the quality of post-war steel, a view borne out by a statement of the British Admiralty. Ha (13)

The Protection of Water Pipes Against Corrosion. *Engineering*, Vol. 141, Feb. 28, 1936, pages 246-247. From a publication by J. E. Carriere entitled "Het in-en uitwendig Beschermen van Gietijzeren en Stalen Leidingen tegen Corrosie" published by Rijksbureau voor Drinkwatervooziening of The Hague, Holland. LFM (13)

Steel Manufactured in France (Les Aciers de Fabrication Française) *Science et Industrie, Métaux et Machines*, Vol. 19, Dec. 1935, pages 437-441. Present section is devoted to wear resisting steels of the Mn and Cr base type and gives for each type, composition, physical properties, heat treatment and welding, mechanical properties at room and high temperatures, corrosion resistance, machinability, applications. Directions for Corrosion Investigations (Richtlinien für Korrosionsversuche) Report of the Deutscher Normenausschuss. *Zeitschrift für Metallkunde*, Vol. 28, Jan. 1936, pages 19-22. A plan for coordinating and standardizing the investigation of corrosion problems in Germany. FNR (13)

COVERING THE ENTIRE
16 GROUPS OF METALS

CORROSION RESISTANCE OF METALS AND ALLOYS

by Robert J. McKay and Robert Worthington

ALL who have to do with metals—producers, manufacturers, distributors and users—find themselves faced with corrosion problems. This book was written primarily to provide help to a man in this situation.

The total annual loss from corrosion is tremendous. In one case the wrong use of metal led to the scrapping of several hundred thousands dollars worth of equipment inside a month or two, in another the loss was nearly as great. These losses would have been entirely avoided if one or two perfectly simple facts of corrosion had been understood. Losses on a minor scale, due to lack of understanding, are innumerable.

Corrosion can be made an extremely complicated subject. The authors have not let it become so in this book. They have taken as the basis of discussion the simple facts of what a corrosive will do to metals or how a metal will behave in the face of corrosives. Insofar as possible they have expressed this behavior in quantitative terms. Involved discussion of the theories of corrosion have been avoided, yet enough of this has been included to provide background. The approach is essentially a practical one.

Corrosion knowledge is rapidly increasing. It is believed that the present work of about 500 pages may serve for years to come as a pattern into which each newly discovered fact may be fitted and which thus may provide this fact with its true and useful interpretation.

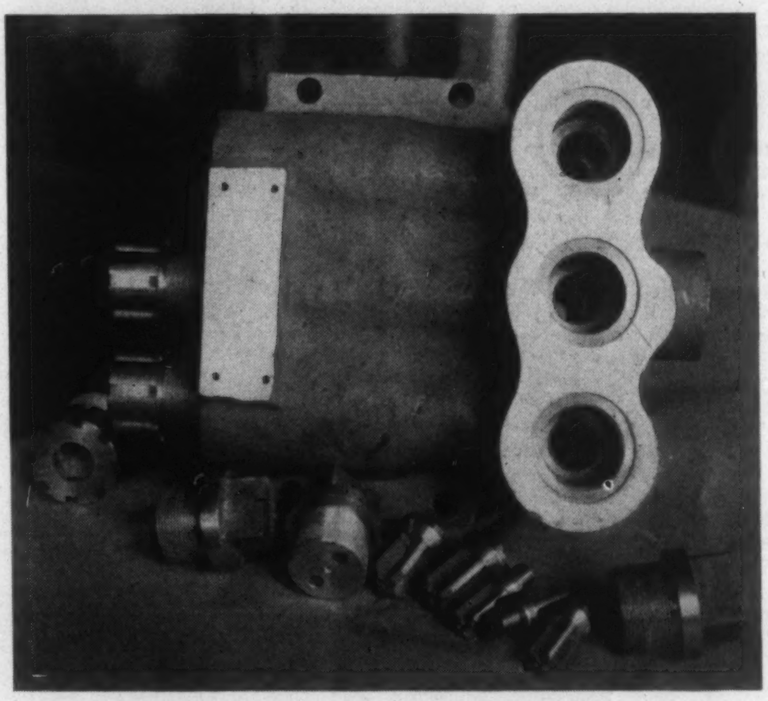
REINHOLD PUBLISHING CORPORATION
330 West 42nd St. New York, U. S. A.

A Pitcher Pump.

A High Pressure Pump



Both of DURIMET

. . . From the simple to the complex . . . and in DURIMET, of course, as both handle corrosive liquids.

A Pitcher pump, in the usual metals, is cheap and can be replaced easily. Yet this customer found it cheaper and infinitely more satisfactory to have the pump made of Durimet. Reasons: complete corrosion resistance and no danger of contamination of his product.

The high pressure pump was formerly made of a solid block of steel, not corrosion-resisting. This pump was cast in Durimet with cored openings and machined in our own shop. It is going into service handling corrosive liquids under high pressure.

You may not need a pump, but you might need some other piece of equipment. Making it of Durimet might be profitable to you. Why not find out for sure? We shall be glad to assist you.

ALLOY STEEL DIVISION
of
THE DURIRON COMPANY, Inc.
432 N. Findlay St. Dayton, Ohio

Some Chemical Aspects of Boiler Plant Maintenance. A. A. Pollitt. *Electrical Review,* Vol. 118, Mar. 27, 1936, page 460. Abstract of paper read before the London Technical Group of the Electrical Power Engineers' Association. Deals, in part, with caustic embrittlement. MS (13)

Wearing Tests with Alloy and Unalloyed Cast Steel (Verschleissversuche mit legiertem und unlegiertem Stahlguss) K. Roesch. *Giesserei,* Vol. 23, Feb. 28, 1936, pages 97-101. 2 methods for testing the wear of cast steels are described, in both the part to be tested is pressed against a surface of 1 cm.^{2} and either moved back and forward or continually over it. Hard Mn cast steel showed rapid increase of wear for very high specific pressure. Hardened steel castings with 400-450 Brinell show a very high wear resistance, e.g. Cr-Ni and Cr-Ni-Mo cast steel. The basis of good wear resistance is pearlite and, to a lesser degree, ferrite. With increasing C content the amount of pearlite increases and therefore also the wear resistance, especially if pearlite is present in coarse laminae; steels with the latter showed 25-30% greater wear resistance than with granular pearlite. A list of publications referring to this subject in the years 1930-35 is added. Ha (13)

Steel Sheets Protected by Sprayed Zinc Coating. W. C. Reid. *Welding Engineer,* Vol. 21, Feb. 1936, page 31. The Zn coating which was destroyed by welding galvanized sheets was replaced by a new sprayed Zn layer which was entirely satisfactory as regards corrosion resistance. Ha (13)

Determination of Oxidation Losses in Rolling-Mill Furnaces (Versuche über den Abbrand in Walzwerksöfen) F. Strähuber. *Stahl und Eisen,* Vol. 55, Nov. 21, 1935, pages 1229-1234. Oxidation losses for various periods of time in different atmospheres are shown in graphs. SE (13)

Investigation of the Question of the Cavitation Erosion of Materials (Versuche zur Frage der Werkstoffanfressung durch Kavitation) H. Schröter. *Zeitschrift für Metallkunde,* Vol. 27, Dec. 1935, pages 287-289. A type of pitting corrosion peculiar to ships' propellers and objects operating under similar conditions has been shown to be due almost wholly to the mechanical errosion caused by the impingement of water moving at high velocities. Glass, bakelite, rubber, Pb, Al, Fe, steel, brass, and bronze were all attacked in the same manner when subjected to the action of a jet of water. It was demonstrated that the resistance of a material to this type of attack is roughly proportional to its hardness. Electrochemical effects appear to play a very minor part, being most noticeable in the case of the polyphase bronzes. The resistance of cast Fe is inferior to that of steel because of the softness of the graphite constituent. FNR (13)

Corrosion Velocity of Duralumin (Zur Korrosionsgeschwindigkeit des Duraluminiums) G. Tammann & W. Boehme. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 226, Dec. 31, 1935, pages 82-86. The effect on velocity of HCl corrosion of Al with Cu in solid solution and precipitated as Al_2Cu was determined. When the Cu is in solid solution, as quenched, the corrosion velocity is a min., heating to 100°, 200°, 300° C. respectively and quenching increases corrosion with 300° C. a max. and higher aging temperatures give decreased corrosion velocity again. WB (13)

Work of French Commission on Corrosion of Metallurgical Products of Interest to Aviation (Recherches relatives aux travaux de la Commission Française de Corrosion des produits métallurgiques intéressant l'aéronautique) R. Legendre Grard & R. Lecoeuvre. *Revue de Métallurgie,* Vol. 33, Mar. 1936, pages 178-188. Summary of the ideas underlying the experimental procedure and its interpretation and presentation as adopted by the Commission. A list of papers published by the workers is given. JDG (13)

Corrosion Problems in the Chemical Industry. James Golder. *Journal West of Scotland Iron & Steel Institute,* Vol. 43, Dec. 1935, pages 43-52. The application of ferrous and non-ferrous metals and of glass lined iron ware for severe corrosion conditions is discussed with numerous examples of both successful and unsuccessful installations. Control of all details and proper understanding of service conditions are essential for satisfactory service. The uses and limitations of various modifications of stainless steel are discussed. These modifications include: 18-8 Cr-Ni, 18-8-1 Cr-Ni-W, 18-8-1-1 Cr-Ni-W-Ti, 18-14-1 Cr-Ni-V, 18-14-2 Cr-Ni-Mo, 18-8-4 Cr-Ni-Mo. FGN (13)

Latex as Economizing and Substitution Material. H. Miedel. *Metalgesellschaft,* No. 11, Feb. 1936, pages 19-24. Besides extensive uses of latex in the textile industry which are described in detail, it is also used to replace in part more expensive materials for protecting metal containers in the chemical and foodstuff industries against chemical influences by spraying a thin layer of latex hard rubber on the metal (especially Fe). The economical advantages, especially from the German point of view in its desire to save expensive imported materials, are discussed at length. Ha (13)

Effect of Composition on the Corrosion Probability of Iron and Steel. R. B. Mears. *Iron & Steel Institute, Carnegie Scholarship Memoirs,* Vol. 24, 1935, pages 69-85. The author shows that scale covered materials give low probability corrosion figures when the scale is coherent and continuous, and comparatively high values when it is loose, scratched, or imperfect. Ferrous and Mn sulphide in aqueous contact with the metal surface increase the probability of corrosion. The presence of hematite or Fe phosphide increases the corrosion probability slightly. Inert substances such as sand, alumina, Fe silicate, magnetite and graphite have no effect. There is a considerable correlation between the corrosion probability value and the amount of S, C, and Mn in the iron. Materials containing high S, C, and Mn give higher average corrosion probability values than those containing low quantities of these elements. Si, P, and C have little effect on the corrosion probability figures. Small quantities of H_2S increase the probability of corrosion of Fe by 0.005 molar $NaHCO_3$ solution, much more than similar amounts of H_2SO_4. CW (13)

The Comparison Between the Effect of Hydrogen-ion Concentration on the Rate of Corrosion of Steel in Pure Oxygen and Air at 25° C. J. M. Bryan. *Transactions Faraday Society,* Vol. 31, Dec. 1935, pages 1714-1718. The main effect of high concentration of O_2 is to mask the effect of pH and to equalize the rate of corrosion in a greater pH range. The evolution of H_2 is inhibited by pure O_2. The acceleration of corrosion in the presence of pure O_2 is entirely due to depolarization. PRK (13)

14. APPLICATION OF METALS AND ALLOYS

Magnesium Alloys in Aeroplanes. E. R. Gadd. *Aircraft Engineering,* Vol. 7, Dec. 1935, pages 299-302. England is now producing Mg from native dolomite ores which are to be found in Derbyshire and other localities. Flux inclusions and 2 forms of porosity are the major difficulties met in casting Mg, flux shows up when part is finish-machined and is shown by local corrosion of the part. Porosity is most serious when present as microscopic type of grain boundary separation. Impregnation is resorted to to make engine component castings pressure tight. Cure for this type of porosity is considered to be in modification of composition. In forging Mg alloys rapid deformation is unsuccessful and greater success is obtained by pressing or extruding. Table of physical and mechanical properties are given for various materials of construction for aircraft for comparison of Mg with Al, etc. Notch tenderness of Mg is greater than Al and tensile test is seriously affected by surface of test specimen. Suggestion made for redesign of casting when Mg is substituted for Al with generous radii and better surface finish. Unless these factors are considered there will be no weight saving over Al. Attempts to use Mg alloy for pistons were unsuccessful due to low thermal conductivity and low strength, 3-5 tons/in.^{2} at 350° C. as compared with 7-9 tons/in.^{2} for Al pistons. Use of Mg alloys in crankcases unsuccessful due to low creep strength at operating temperature. The use of forged Mg alloy, variable pitch propellor is discussed as an important and desirable use of Mg for weight reduction. Other successful applications are for landing wheels, panels, cowlings, oil and fuel tanks, (the latter, however, not in England). Corrosion problems with use of Mg are serious and attempts to prevent corrosion by chromate process and Se deposit, all require after treatment with one or more coats of enamel. As regards galvanic action, the combination of 13% Cr steel-Mg is not nearly as destructive of the Mg as when it is in contact with 18-8. In use of Mg alloy for carburetors as a substitute for Al alloys it is necessary to use 13% Cr steel for bushings instead of the bronzes used with Al. The use of Mg alloys for fuel tanks holding leaded fuel, is reported to be successful on the continent due to suspension of a bag of NaF in the tank to form F salts with moisture in the fuel. The Mg F film formed protects the base against corrosion. WB (14)

Materials of Construction for Chemical Engineering. J. McKillop. *Chemical Trade Journal & Chemical Engineer,* Vol. 96, Apr. 5, 1935, pages 249-250. From paper read before Institution of Chemical Engineers and Manchester Metallurgical Society. Includes consideration of Cr-Ni steels, Fe castings with 6-13% Si, Te-Pb alloys, Al, and Pb-lined and Ni-clad steel. MS (14)

Use of Pure Molybdenum in Electrical Industry (Le Molybdène Pur en Electricité) M. Deribéré. *Science et Industrie, Electricité,* Vol. 19, Dec. 1935, page 553. Pure Mo wire is used for inside contacts and wire and grid supports in lamps and radio tubes, anticathodes for X-ray tubes, electrodes for spark plugs, etc. Mo is also used for heating resistances which can work up to 1500° and even 2000° C. instead of 1000° for Ni-Cr and 1300° for graphite, but Mo resistance must work in H atmosphere. Alloys of Mo such as W-Mo and Ni-Mo have also found applications in the electrical field. FR (14)

14a. Non-Ferrous

G. L. CRAIG, SECTION EDITOR

Use of Aluminum Foils in the Household (Verwendung von Aluminiumfolien im Haushalt) A. Singer. *Aluminium,* Vol. 18, Jan. 1936, pages 29-30. Bread and meats can be kept fresh by wrapping in Al foil; in baking it prevents the baked dough from sticking to the form. It is used for decorative purposes and is very effective as a scarecrow as the continuously changing reflection of light by the motion of the foil in the wind scares birds away. Al foil is absolutely sterile, germ-free and harmless. Ha (14a)

Copper as a Chemical Plant Material. C. H. S. Tupholme. *Chemical Industries,* Vol. 37, Nov. 1935, page 448. A brief discussion of the corrosion resistant properties of Cu and some of the conditions under which Cu can be used. RAW (14a)

Aluminum for Railway Rolling Stock Construction. A. H. Woollen. *Railway Age,* Vol. 100, Feb. 22, 1936, pages 303-308. A review of the applications of Al alloys to rolling stock. CBJ (14a)

A New Metal Mallet (Ein neuer Metallhammer) K. Wissemann. *Aluminium,* Vol. 17, Dec. 1935, page 644. An alloy of Al-Zn with 7-15% Zn was found to be a very suitable material for a metallic hammer as a substitute for lead hammers as it keeps its shape much longer and is sufficiently deformable not to damage the metal parts on which it is used. Ha (14a)

Requirements of Materials for Weaving Fourdrinier Wires. Hugh E. Brown. *Wire & Wire Products,* Vol. 11, Jan. 1936, pages 15-18, 54. See *Metals & Alloys,* Vol. 6, Oct. 1935, page MA 422L/1. Ha (14a)

New Use for Tin Compounds. E. W. J. Mardles. *Chemical Trade Journal & Chemical Engineer,* Vol. 95, Oct. 12, 1934, page 256. See "The Beneficial Use of Tin Compounds in Lubricants," *Metals & Alloys,* Vol. 5, Dec. 1934, page MA 590. MS (14a)

Application of Welded Aluminum. G. O. Hoglund. *Industry & Welding,* Vol. 8, Jan. 1936, pages 52-56. The characteristics of Al and Al alloys as far as they must be considered in welding are described, welding processes discussed, and typical mechanical properties of wrought Al alloys (16 types) given in a table. Examples of welded structures and apparatus for architectural applications in the transportation field, in brewery and dairy, and in chemical handling equipment are described. Ha (14a)

Aluminum as a German Construction Material (Aluminium ein deutscher Werkstoff für den Apparatebau) H. RÖHRIG. *Chemische Fabrik,* Vol. 8, Dec. 11, 1935, pages 487-489. Commercial Al is now obtainable 99.7% pure. For special purposes a 99.7-99.8% grade is also available. Its cost is higher but its corrosion resistance, especially to HCl is superior. The impurities are mainly Fe and Si. Si is put in solid solution by heating to 400°-500° C. to reduce its harmful effect. Mg is added for resistance to alkalies. Silumin is used for contact with oils and fatty acids. It is important not to damage the oxide coating by scratching or embedding chips of heavy metals, especially Cu. Artificial oxide coatings give better corrosion protection than the natural oxide. The attack of alkali solutions on Al is prevented by adding .5% Na silicate to the alkali which forms a colloidal protective coating. Other colloids can also be used with alkaline sulphides, dyes, alkaline disinfectants and cleaners for milk containers, and alkaline tooth pastes. Colloids are effective in reducing the attack of acids such as HCl on Al, but other inhibitors are used, similar to those used in steel pickling solutions. Al is suitable for chemical equipment because it is easy to form and weld. Autogenous, hammer, arc and resistance welding processes are used. Hammer welding is not suitable if the weld is to be in contact with HCl. CEM (14a)

Traffic Signs of Light Metal (Verkehrschilder aus Leichtmetall) FRITZ RENTEL. *Aluminium,* Vol. 17, Nov. 1935, pages 568-569. Discusses atmospheric corrosion resistance of aluminum. Ha (14a)

Use of the Heat Conductivity of Aluminum for Heating of Floors, System Deriaz (Anwendung der Wärmeleitfähigkeit von Aluminium bei der Fussbodenheizung, System Deriaz) *Aluminium,* Vol. 18, Jan. 1936, pages 19-21. Al heating tubes (radiators) in which hot water or steam circulates were installed in the floor of rooms and proved to be very effective. A more even temperature distribution over section and height of the room was obtained than with the radiators distributed as usual. Ha (14a)

Bell Metal in Bengal. *Aluminium & the Non-Ferrous Review,* Vol. 1, Dec. 1935, page 114. An alloy of 60% Cu, 10% Sn, 30% Zn has been proposed by the Department of Industries, Bengal, India, as a substitute for the traditional alloy of 77% Cu, 23% Sn commonly used for food utensils. JCC (14a)

The Development of the Metal Aeroplane. *Aluminium & the Non-Ferrous Review,* Vol. 1, Dec. 1935, pages 95-96, 98-99. An historical review. JCC (14a)

Fifty Years Development of Important Canning Medium. *Canning Age,* Vol. 17, Feb 1936, pages 69-71. A discussion is given of the advantages and value of Al in the canning industry, both in the form of metal containers and as paint. Non-toxicity, lightness, good heat conductivity, sanitary appearance and resistance to corrosion are outstanding properties. In one investigation it was found that an Al alloy for handling citrus fruit juices was uniformly attacked at a rate of only 0.00017" penetration per year by lemon juice, 0.00020" by orange juice and 0.00024" by grapefruit juice. Al Mason jar tops and even Al cans are now being used. From the successful use of flat Al cans with pressed-on covers for packing tuna—despite the slight premium which the customer had to pay—experiments are now being made to demonstrate the practicability of Al cans for many food products. BWG (14a)

Contemporary Pewter in the Netherlands. *Bulletin No. 3, International Tin Research & Development Council,* Jan. 1936, 62 pages. Price 2s. 6d. post-free, may be obtained free of charge by educational and kindred establishments. Profusely and artistically illustrated. A brief description of the methods of making hand-wrought pewter is included. Of interest to metallurgists as an outlet for metals, and to those of artistic leanings from the beauty of the objects pictured. HWG (14a)

Caustic Soda Evaporation. *Chemical Trade Journal & Chemical Engineer,* Vol. 97, Nov. 8, 1935, page 395. Ni and Monel metal have given excellent service in construction of NaOH evaporators. Where Cu-free product is desired, pure Ni is best. MS (14a)

Chemical Works' Piping Systems. *Chemical Trade Journal & Chemical Engineer,* Vol. 95, July 6, 1934, page 8. Discusses use of Monel metal piping installations in chemical and allied industries. MS (14a)

Castings for Chemical Plant. *Chemical Trade Journal & Chemical Engineer,* Vol. 94, June 29, 1934, page 485. Outlines uses of Ni and Monel metal in chemical equipment where resistance to corrosive media and non-contamination of product handled are required. MS (14a)

Some General Remarks on Copper Compounds (Quelques Généralités sur les Composes du Cuivre) *Cuivre et Laiton,* Vol. 8, Dec. 30, 1935, pages 551-553. The different compounds of Cu which are used in the paint, ceramic, glass, dyeing and other industries are reviewed and their compositions and applications briefly described. Ha (14a)

The Commercial Development of Tungsten. *Engineering,* Vol. 141, Feb. 7, 1936, page 158. Briefly outlines the various uses of W and its compounds and gives some of the recent developments leading to new uses. LFM (14a)

Bronze Bearing Metals. *Mechanical World & Engineering Record,* Vol. 98, Nov. 15, 1935, pages 477-479. A special study of the use of bronze for bearing metals has led to the development of a series of alloys to suit particular circumstances and applications. Some cases are detailed which show the need for matching the bearing alloy to the bearing duty. WH (14a)

Free Cutting Aluminum for Screw Machine Work. *Steel,* Vol. 97, Dec. 23, 1935, pages 27-28. Similar to *Iron Age,* Vol. 136, July 25, 1935, pages 27-29. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 84L/7. MS (14a)

Redesigning to Use Aluminum. GEO. W. DEBELL. *Product Engineering,* Vol. 7, Feb. 1936, pages 42-45. The most important points to be considered when designing with Al or Al alloys to obtain members of equal strength and stiffness as with steel are discussed. The points are exemplified by use of Al in railways. Ha (14a)

Etching Process for Name Plates and Dials. HARRY SHELLY. *Platers' Guide,* Vol. 32, Feb. 1936, pages 12-16. Applications of etching processes are outlined. Difficulties of etching and plating Al are emphasized. WHB (14a)

Using CHACE Thermostatic BIMETAL

I-T-E CIRCUIT BREAKER COMPANY

Chace Thermostatic Bimetal is used as the active element in I. T. E. Circuit Breakers to assure unfailing automatic overload protection.

Regardless of the product you manufacture, if given changes in temperature demand certain automatic action, or if it be a matter of automatically controlling temperature, we suggest you consider using Chace Thermostatic Bimetal. Sold in sheets, strips and formed to meet specifications.

CHACE THERMOSTATIC BIMETAL
"It Bends with the Heat"

W. M. CHACE CO.
1615 Beard Avenue - - - Detroit Mich.

M. GENSAMER, SECTION EDITOR

Weight, Machine Parasite, Cut with Low-Alloy Steels. ALLEN F. CLARK. *Machine Design,* Vol. 7, Dec. 1935, pages 15-18. Discusses Cr-Mn-Si, Mn-Si, Mn-Si-Cr-Cu, Cr-Mo-Cu, Ni, and Mo (low alloy) steels. Physical properties and chemical analyses are listed and applications are pointed out stressing weight saving designs. WH (14b)

Rustless Austenitic Steels in the Dyeing Industry (Los Aceros inoxidables austeniticos en la Industria tintorera) A. BUZZANCA. *Metalurgia y Construccion Mecanica,* Vol. 1, Feb. 1936, pages 4-6. Economies obtained in the use of austenitic Cr-Ni steels for machinery in the textile and dyeing industry because of their resistance to acids and easy handling and assembling by welding are discussed. Ha (14b)

Crates for Bottle Sealed Oil Are Built of Steel Sheets and Flat Wire. *Steel,* Vol. 98, Feb. 10, 1936, pages 45-46. Describes 2 types of crates, parts of which are formed under heavy pressures and assembled by spot welding. They are cleaned, degreased, bonderized, and finished with 1 coat of baked enamel. MS (14b)

Steel Wire Splint Has Advantages. *Steel,* Vol. 98, Feb. 24, 1936, page 61. Describes wire gauze splint, for medical and surgical work, made of standard hardware cloth, reinforced with fine-gage strip steel. Both wire and strip are of Cu-bearing steel. Splint is soft annealed and finished by hot-dip galvanizing. It is easily folded to correct length and molded with fingers to fit injured part. MS (14b)

New Permanent Magnet Can Lift 60 Times Its Weight. *Inco,* Vol. 13, No. 3, 1935-36, pages 10-11. The permanent magnet is made of an Al-Ni-Co alloy (alnico), and owes its excellent magnetic qualities to the fact that it is precipitation-hardening and that its components form carbides in fine distribution. It is non-corrosive, fairly brittle, is used in cast state, and has a sp. gr. of 6.9. Ha (14b)

Alloy Steel Developments. *Blast Furnace & Steel Plant,* Vol. 24, Jan. 1936, pages 49-50. Discusses expanding uses of Cr steels. Tendencies are to use inexpensive mild alloy steels of high tensile strength, such as Cromansil steel, in place of plain C steel; to use more Cr, so that in many cases minimum amount in steel is 11%; and to add Cb to grades other than 18-8 to impart desirable properties. MS (14b)

The Fabrication of Diesel Engine Crankcases. J. THOM. *Welder,* Vol. 8, Dec. 1935, pages 791-792. Electric arc welding in modern locomotive practice is discussed and exemplified by the description of the welded construction of a crankcase for a 1200 h.p. Diesel engine. The case is made up of 267 individual parts. Ha (14b)

The Use of Rock Drills on the Mines. R. S. G. Stokes. *South African Mining & Engineering Journal,* Vol. 46, Part II, Dec. 28, 1935, pages 569, 571-572. From "Recent Developments in Rand Mining Practice," read before Institution of Mining & Metallurgy. Trends in composition of drill steel are discussed. AHE (14b)

Cast Iron for Chemical Plant. J. G. Pearce. *Chemical Trade Journal, & Chemical Engineer,* Vol. 95, Nov. 16, 1934, pages 351-352. See "Modern Cast Irons in Chemical Engineering," *Metals & Alloys,* Vol. 6, Sept. 1935, page MA 378L/8. MS (14b)

Enamelling of Iron. N. H. Oakley-Evans. *Chemical Trade Journal & Chemical Engineer,* Vol. 96, Jan. 4, 1935, pages 7-8. See "Pure Iron for the Enamelling Industry," *Metals & Alloys,* Vol. 6, June 1935, page MA 257L/9. MS (14b)

Cast Ferrous Alloys in the Paper Industry. F. L. LaQue. *Paper Trade Journal,* Vol. 102, Jan. 30, 1936, pages 34-36. A complete flow-sheet for the manufacture of paper by the various processes is given. Table keyed with reference to the flow-sheet gives the materials used in the construction of the various units. CBJ (14b)

Cast Iron in the Chemical Industry (La Fonte dans l'Industrie chimique) A. Guedras. *Revue de Fonderie Moderne,* Vol. 29, Dec. 10, 1935, pages 355-361. Properties which a cast Fe must possess to be a satisfactory material in the chemical industries are discussed. Quite generally the elements used in cast Fe in the order of their importance are, (1) Si, used for handling acidic minerals, (2) Ni, up to high contents; but under alkaline action it should be between 1.5 and 2%, (3) Cr, (4) Mo, which are both added to give a corrosion-resistant material under chemical action, and (5) C, which must always be in the combined state and in case it exists in the graphitic state, must be in extremely fine dispersion as in pearlitic cast Fe. 7 references. Ha (14b)

Staybrite Steel as Applied to the Dyeing Industry. F. Godber. *Journal Dyers & Colourists,* Vol. 52, Feb. 1936, pages 45-48. Staybrite steel contains essentially 18% Cr and 8% Ni. Advantages claimed for its use in the textile industries are: (1) it eliminates damage to fabrics caused by rust and metal staining, (2) it lengthens the life of the plant and reduces the loss of time due to frequent attention, (3) it has alloy steel strength, (4) it is easily cleaned and changes of coloring matter can follow in the same vats in sequence, (5) no boiling out is necessary, (6) a Staybrite steel vat does not absorb dyes, and (7) the resistance offered to the attack of many chemicals does not depend on any surface treatment or superficial plating. WHB (14b)

Simplicity Is Achieved in Steel Garden Chair. *Iron Age,* Vol. 136, Oct. 3, 1935, pages 25. Describes new model steel chair made by L. J. Zerbee & Co., Bellefontaine, O. Instead of having tubular frame between which cross-members are welded or bolted, the entire seat and back is made of a single piece of sheet steel. Strip of automobile spring steel is bent to form the leg and arm. Chairs are made with Cr-plated arms and legs, or in various color combinations in enamel. VSP (14b)

What the S. A. E. Steel Specifications Mean. *Industry & Welding,* Vol. 7, Sept. 1935, pages 53-56. See "New S. A. E. Steel Data Embody Wide Engineering Significance," *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 38L/1. Ha (14b)

Iron Reinforces Concrete Roads. *Foundry,* Vol. 63, Nov. 1935, pages 35, 68. Reviews material taken from "Armature e pavimentagioni metalliche" on cast Fe roads in Italy. Castings are triangular grids placed on road surface and filled with concrete. Discusses shapes other than triangular and also systems used in France and Germany. VSP (14b)

"Isteg" Steel Bars for Concrete Reinforcement. *Engineering,* Vol. 140, Nov. 8, 1935, pages 508-509. The "Isteg" bar consists of 2 strands of ordinary quality mild steel twisted together. The twisting is done cold which results in the material giving a stress-strain diagram without a well-defined yield point so the bars can be stressed well beyond that of a plain bar of the same material. Some tests were carried out on these bars. An "Isteg" rod stressed at 27,000 lb./in.^{2}, consisting of bars each 7/16" in diameter and weighing 1.022 lb./lineal foot is equivalent to a single plain rod stressed at 18,000 lb./in.^{2}, ¾" in diameter and weighing 1.502 lb./ft.^{2} Tests were also made to determine the degree of anchorage of "Isteg" and plain bars in the concrete matrix. The "Isteg" bars were cut off square at the end while the plain bars had the customary hooks. In all tests the "Isteg" bars proved to be superior to the plain bars. LFM (14b)

Standard Specifications for Forge-Welded Steel Pipe. *American Society for Testing Materials,* A. S. T. M. Designation: A136-34; *American Standards Association,* A. S. A. No.: B36.6-1935, 5 pages. AHE (14b)

Standard Specifications for Zinc-coated (Galvanized) Iron or Steel Tie Wires. *American Society for Testing Materials,* A. S. T. M. Designation: A112-33; *American Standards Association,* A. S. A. No.: G8.4-1935, 4 pages AHE (14b)

Standard Specifications for Zinc-coated (Galvanized) Iron or Steel Telephone and Telegraph Line Wire. *American Society for Testing Materials,* A. S. T. M. Designation: A111-33, *American Standards Association,* A. S. A. No.: G8.3-1935, 6 pages. AHE (14b)

Standard Specifications for Zinc-Coated (Galvanized) Iron or Steel Wire Strand (Cable). *American Society for Testing Materials,* A. S. T. M. Designation: A122-33; *American Standards Association,* A. S. A. No.: G8.6-1935, 6 pages. AHE (14b)

Standard Specifications for Zinc-Coated Iron or Steel Chain-Link Fence Fabric Galvanized After Weaving. *American Society for Testing Materials,* A. S. T. M. Designation: A117-33; *American Standards Association,* A. S. A. No.: G8.5-1935, 3 pages. AHE (14b)

15. GENERAL

RICHARD RIMBACH, SECTION EDITOR

Alloys and Metals at the Ford River Rouge Plant. *Mill & Factory,* Vol. 18, Jan. 1936, pages 429-455. Forging, casting, heat-treatment, plating, polishing and painting operations are described in considerable detail. Forging developments include simplification of operations, use of automatic feeding, and typing instead of cutting dies. Forging furnaces are largely gas-fired, with duplicate oil fueling available. The manufacture of steel-backed Cu-Pb bearings is characterized by continuous casting of Cu-Pb on both sides of a steel strip, which is in turn formed into a semicircle and machined to bearing size. Complete analysis specifications and Ford standard designations of 53 types of steel used in the car are tabulated. The melting, pouring, etc. of the cast alloy steel piston and the revolutionary cast alloy Fe camshaft and crankshaft are described. Cast Fe cylinder blocks are poured continuously at the rate of 850 tons of metal per 16 hour day. 25 bell-type furnaces, each with a 22,000 lbs. capacity, satisfy the strip steel bright annealing requirements. Metal cleaning is accomplished with either alkaline solutions or organic solvents and with sand, shot and steam jet blasting, and electrolytic cleaning. Non-ferrous metal operations include die-casting of Zn parts with permanent molds and Cu-Ni, brass, Cr, Cd and Zn plating of various parts. "Granodizing," the electrolytic deposition of Zn phosphate with alternating current, is the rust proofing method used for most pieces, although fenders and other very large sections are rust-proofed by conventional methods. 32 heat treating operations are described, with details of temperatures, cool or quench media, hardness and uses of the treated part or tool. The processes of hard Cr and bright Cr plating, rust-proofing, Butler finishing, etc. are minutely detailed, and the salt spray tests and finish-quality specifications are outlined. FPP (15)

New English Steel Works in Corby (Neues englisches Hüttenwerk in Corby) *Stahl und Eisen,* Vol. 55, Nov. 14, 1935, pages 1214-1219. General description of blast furnaces, basic bessemers, and rolling mills. SE (15)

Molybdenum. Its Ores. Its Industry (Le Molybdène. Ses minerais. Son Industry) M. Deribéré. *Science et Industrie, Métaux et Machines,* Vol. 19, Dec. 1935, pages 407-411. Reviews chief forms under which Mo is found in nature. Molybdenite is said to be the most common ore for practical metallurgy. Historical sketch of Mo is given. Physical and chemical properties are discussed. Then general applications are reviewed, i.e.: silico-Mo is of little use. Mo steels with 5-10% Mo are tool steels, steels with 0.5-2% Mo are intended for structural purposes. Mo is commonly used in complex steels such as Si-Mo of the Durichlor type, Cr-Mo, Cr-Al-Mo, Cr-Mn-Mo, Ni-Mo, Ni-Cr-Mo steels, the latter for case hardening purposes, Ni-Cr-Mo steel, special attention being given to the latter type of steel which has many applications, particularly as castings, which have as high a wear resistance as high Mn steel castings and have a better weldability. Ni-Cr-Al-Mo steel for case hardened parts having a thick hardened depth by quenching, Mn-Mo, Co-Mo steels, the latter being a new development in the permanent magnet field. Last section of the article deals with Mo cast Fe. FR (15)

Investigation of Alloys Prepared by Ceramic Methods. N. Zarubin & M. Suitin. *Redkie Metallui,* Vol. 4, July-Aug. 1935, pages 21-25. In Russian. Alloys of WC and Fe containing 5-90% WC and of Mo_2C and Fe containing 2 to 90% Mo_2C were prepared by sintering at 1450° C. for 1.5 hours. The solubility of WC in Fe was found to be about 5% and of Mo_2C about 2%. In both systems eutectics containing about 30% carbide are formed. HWR (15)

Production of High Quality Hard Alloys. N. M. Zarubin. *Redkie Metallui,* Vol. 4, Nov.-Dec. 1935, pages 18-23. In Russian. The presence of free C in the WC-Co mixture causes a porous microstructure. The presence of free W or of Co oxide causes segregation in the sintered alloy. HWR (15)

Some Aspects of the Selection of Engineering Materials. L. B. Hunt. *Proceedings Institute of British Foundrymen,* Vol. 26, 1932-1933, pages 479-500. See *Metals & Alloys,* Vol. 4, Dec. 1933, page 377. CEJ (15)

Metallurgical Processes in Iron and Steel. Stanley R. Keith. *Iron Age,* Vol. 137, Jan. 2, 1936, opposite page 120. A chart claimed to be the most comprehensive, traces in detail the wide-spread branches of iron and steel manufacture. Of reference value to consumers as well as producers. VSP (15)

The Steel Works of the South African Iron and Steel Industrial Corporation in Pretoria (Das Hüttenwerk der South African Iron and Steel Industrial Corporation in Pretoria) W. Krebs. *Stahl und Eisen,* Vol. 55, Oct. 3, 1935, pages 1057-1065. Layout and practice are described. SE (15)

Modernization Miracles. *Mill & Factory,* Vol. 18, Jan. 1936, pages 89-108, 585. Detailed description is given of the general expansion and modernization program of the Ford Motor Co.'s River Rouge plant. Blast furnace "B" was enlarged and rebuilt, increasing its capacity 60%. New hot strip and cold finishing rolling mills, capable of rolling a 10 ton ingot to .065" sheet in 12 minutes with a single reheat were provided at a cost of 10 million dollars. Complete description of capacity and equipment of new mills, auxiliary heating equipment, conveyors, etc., and a process flow chart of the entire steel plant, with roll pass details, are included. FPP (15)

Screwing Light Metal Screws into Wood (Ueber das Endrehen von Leichtmetallschrauben in Holz) Nicolini. *Aluminium,* Vol. 3, Feb. 1936, pages 60-62. In order to make light metal screws turn easily into hard wood it is recommended to dip them in molten wool fat. The effect can still be enhanced by reinforcing previously the natural oxide film by the eloxal process. Ha (15)

15a. Economic

Future Development of German Iron Foundries (Die zukünftige Entwicklung der deutschen Eisengiessereien) TH. GEILENKIRCHEN. *Giesserei,* Vol. 23, Jan. 17, 1936, pages 25-27. Formation of a cartel among the iron foundries to promote unification of production and products, improvement of qualities and general economical conditions are discussed. The future trend will be to use a high-grade cast Fe which approaches forged and cast steel; castings of much thinner walls will be used in machine tools and machinery in general to compete with light metal constructions. A still more pronounced utilization of scientific results in practice is to be expected. Ha (15a)

Economic Conditions in South Africa. A. W. H. HALL. *Iron & Coal Trades Review,* Vol. 132, Feb. 28, 1936, page 405. Report of the Overseas Trade Department on Fe ore resources and imports of Fe and steel. Ha (15a)

Iron and Steel Imports into Finland. KEITH JOPSON. *Iron & Coal Trades Review,* Vol. 132, Mar. 27, 1936, page 591. Statistics on the economical conditions and the various Fe products figuring in the trade with Great Britain. Ha (15a)

The World Iron and Steel Industry. WM. J. LARKE. *Iron & Coal Trades Review,* Vol. 132, Jan. 17, 1936, pages 120-121. Review, statistical charts and outlook on potential world consumption. Ha (15a)

Consumer Requirements Now Dictate Mill Equipment. T. W. LIPPERT. *Iron Age,* Vol. 137, Jan. 2, 1936, pages 430-431, 434, 436, 438, 440, 442, 444-445. Reviews some of the more important developments in steel mill practice, such as continuous and strip mills, cold rolling practice, use of antifriction bearings, strip making by slitting continuous sheets, cold forming of shape, and advancements in annealing and sorting sheets, and new ingot heating furnace. VSP (15a)

Consumption of Non-Ferrous Metals Increased in 1935. NEIL E. MACMILLAN. *Iron Age,* Vol. 137, Jan. 2, 1936, pages 130-133. Marketing of non-ferrous metals, though faced with conflicts and uncertainties, improved. Consumption of Cu, Pb, Sn and Zn during 1935 was in each case greater than in 1934. Includes table and graph showing production and price of non-ferrous metals for a number of years. VSP (15a)

Presidential Address. W. R. BARCLAY. *Journal Institute of Metals,* Vol. 58, Mar. 1936, pages 131-152 (Advance Copy No. 729). **The Non-Ferrous Metallurgical Industry.** *Engineer,* Vol. 161, Mar. 13, 1936, pages 282-284. Describes development organizations of the Ni, Al, Cu and Sn producers. Work of each of these organizations is described, and the fields that should be covered by such groups are discussed. JLG + VSP (15a)

Light Materials Gain Favor Among the Railroads. *Iron Age,* Vol. 137, Jan. 2, 1936, pages 56-57. Railroad buying declined in the first 11 months of 1935. Despite this decrease, the outlook at the end of the year was regarded as auspicious. For the new streamlined trains stainless steel and Al alloys were in demand. In freight equipment field, low-alloy high-tensile steels were used. Bringing out of light high-tensile materials caused new developments in rolling mill practice. VSP (15a)

Scrap Exports Gain in 1935. *Iron Age,* Vol. 137, Jan. 2, 1936, page 90. Export of scrap Fe and steel is estimated at 2,140,000 tons, as against 1,835,554 tons in 1934. The exports to each country were:

Japan	991,828	tons
Italy	322,541	”
United Kingdom	219,512	”
Poland and Danzig	36,040	”

Gives a chart showing Fe and steel scrap exports by months in relation to weekly steel ingot rate, and composite price for heavy-melting steel. VSP (15a)

Steel Housing Progress in 1935. *Iron Age,* Vol. 137, Jan. 2, 1936, pages 140-142. Lists the various concerns building steel houses, the number of houses built by each, kind of steel used and average number of tons of steel used for each house. VSP (15a)

Steel Industry Undertook Many Improvements in Plant Facilities During 1935. *Iron Age,* Vol. 137, Jan. 2, 1936, pages 124-125, 128-129. Lists the major improvements completed during 1935 or under way at the end of the year. VSP (15a)

A Symposium on Progress. *Iron Age,* Vol. 137, Jan. 16, 1936, pages 14-23. Gives the opinion of a number of American and foreign metallurgists, and industrialists on the most conspicuous improvements in manufacturing procedure or outstanding contributions to metallurgy during the past year. VSP (15a)

Iron and Steel Trade with Lithuania. *Iron & Coal Trades Review,* Vol. 132, Feb. 21, 1936, page 348. Report of the Overseas Trade Department (Great Britain) on economic conditions in Lithuania, in particular on the industries which at present employ only 20,000 workers. Conditions in Fe consumption and manufactured goods are described. Ha (15a)

The German Economical Aluminum Situation in 1935 (Die deutsche Aluminiumwirtschaft im Jahr 1935) A. DEDERER. *Aluminium,* Vol. 18, Feb. 1936, pages 66-69. The development of the German Al industry in 1935, production, consumption, import and export and the role which Al plays in German international trade relations are discussed. Ha (15a)

International Annual of Minerals and Metals (Annuaire International des Minerais et Métaux). Société des Publications Minères et Métallurgiques, Paris, 1935. Fabrikoid, 6½ x 10 inches, 395 pages. Price 55 Fr. Directory of producers in France, French colonies, Luxemburg, Belgium and Belgium Congo. (15a)-B-

Extra WIDE FLATS

Convenient Steel Sections, *cold drawn* to true flatness and straightness with close size tolerances. Widths up to 12" and thickness from ¼" to 2"—*cold sawed* to length. Well adapted for bed plates and similar machine parts where accuracy contributes to economy and good workmanship. Your inquiries are invited.

Inspection of Cast Iron Pipe in the Late Nineties. R. A. BULL. *Metals & Alloys,* Vol. 6, Nov. 1935, page 332. Descriptive. WLC (15b)

Nickel and Cobalt Refining. *Chemical Trade Journal & Chemical Engineer,* Vol. 96, May 10, 1935, pages 355-356. History of Henry Wiggin and Co., Ltd., which has been in business 100 years. MS (15b)

Metallurgy of Gold and Platinum Among the Pre-Columbian Indians. PAUL BERGSOE. *Nature,* Vol. 137, Jan. 4, 1936, page 29. Discusses new finds of half-finished objects of Au, Pt and Au-Pt alloys from Ecuador. The objects are never cast, but are wrought or made from plate or wire and throw light on the metallurgical processes of the South American Indians before the time of Columbus. Au was melted on wood charcoal with the aid of a blowpipe; wires were drawn from 2 mm. to 0.1 mm. diameter. Pt cannot be melted by primitive means. Pt grains were apparently mixed with Au and joined by melting the Au, which diffused into the Pt; alternate heating and hammering eventually produced a homogeneous Pt-Au alloy (about 30% Au). CSB (15b)

History of Tin Plating. A. EYSPAMER. *Monthly Review American Electroplaters' Society,* Vol. 23, Jan. 1936, pages 25-37. Electroplating of Sn had not been applied extensively until the recent application on coils and other parts of domestic refrigerators. Plating Sn by immersion, on the other hand, has been done on large quantities of pins, thimbles, buttons, etc., made of brass. A common solution for immersion tinning is a saturated solution of cream of tartar plus 15-30 g./l. of Sn chloride. Articles are placed in the boiling solution and kept in contact with metallic Sn. Other formulas are given with references. Many additional references are given, with brief notes and formulas, on the electrodeposition of Sn using external current. GBH (15b)

Alloy Steels—A Historical Review. FREDERICK B. HUFNAGEL. *Blast Furnace & Steel Plant,* Vol. 24, Jan. 1936, pages 81, 84. Address before American Institute Metal Products Exhibit. Egyptians and American Indians used meteoric Fe. Swords of Middle Ages contained alloying elements. First scientific study of Fe and steel alloys was made by Faraday in 1820. Commercial alloying was introduced by Mushet shortly after 1850 and was confined to tool-steels until 1890, when Ni steel was used for armor-plate. Greatest progress has been made in this century. History of Hammer and Wire Mills in Ferlach and Waidisch (Zur Geschichte der Hammer- und Drahtwerke in Ferlach und Waidisch) LUDWIG JAHNE. *Montanistische Rundschau,* Vol. 28, Feb. 16, 1936, pages 1-4. A historic review of 2 Austrian metallurgical plants which date back to about 1650. While the Waidisch plant was closed down permanently about 40 years ago, the Ferlach mill has been modernized and is still in operation. The entire mill is now electrified. BHS (15b)

FREE SERVICE DEPARTMENT

Wanted:—By a well-known manufacturer of Heat and Acid Resisting Castings Sales Representatives who are acquainted with buyers and operating heads in the Steel, Automobile, Chemical and Oil Industries in the following territories: New York, Boston, Philadelphia, Chicago, Cincinnati, Houston and Birmingham. No objection to one or two more lines. Reply giving references and full information as to qualifications. Address Box MA-2, Care of Metals & Alloys, 330 W. 42nd St., New York, N. Y.

REPRESENTATIVE WANTED—A manufacturer of heat resisting alloys and castings seeks representation in both the Philadelphia and New England territories. We are looking for a manufacturer's representative now calling on metal working plants who has the entree to the heat treating supplies market. Write Box No. MA-3, METALS & ALLOYS, 330 42nd Street, New York, N. Y.

Junior Executive Available—M. I. T. Graduate. General engineering experience, Chase Brass and Copper Company. Purchasing chemicals and equipment, R. H. Macy and Company. Single, Christian, references. Box No. MA-4, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

POSITION WANTED: INSPECTOR, SUPERVISOR or INSTRUCTOR of WELDING. Specialized 8 years in arc welding. Knowledge of Metallography, Heat-Treating and Physical Metallurgy. Capable of performing tests and conducting investigations of Weld-Metal. Sales experience. Member of American Welding Socy. and American Socy. for Metals. Good Linguist. Consider position outside U. S. Available July First. Address box MA-6, care of METALS & ALLOYS, 330 W. 42nd Street, New York, N. Y.

FURNACE DESIGNER—Wanted by a manufacturer of electric furnaces. Man with experience designing and estimating electric heat treating furnaces; batch, continuous and salt bath. Give full details of experience, references and salary desired in first letter. Position will be permanent to right man. Address Box No. MA-7, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

METALLURGIST AVAILABLE.—A young man, a graduate Chemical Engineer now employed, who has had more than seven years of experience covering all phases of both ferrous and non-ferrous physical metallurgy, including a knowledge of materials and their applications, heat treating, metallurgical, physical, and corrosion testing, is seeking a new connection with opportunities for increased responsibility and salary. For further information write to Box MA-8, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

History of Iron (Eisen in geschichtlicher Darstellung) MAX PASCHKE. *Giesserei*, Vol. 22, Nov. 8, 1935, pages 553-561. Development of production of Fe in general and in Germany in particular is given. 25 references. Ha (15b)

On the Structure of Armor, Ancient and Modern. WILLIAM CAMPBELL. *Metals & Alloys*, Vol. 6, Oct. 1935, pages 267-272. Shows 19 micrographs of armor steel dating back to 1460. WLC (15b)

Cast Iron—It Dates Back to 300 B.C. RALPH M. SHAW. *Iron Age*, Vol. 137, Jan. 30, 1936, pages 24-27. Recent findings show that the metallurgy of Fe and steel had its real beginnings in ancient China and not in Europe. According to writings of H. T. Chang the age of cast Fe originated between 300 B. C. and 100 A. D. Dawn of the age of Fe may be assigned to centuries preceding the period of Ch'un-Chiu, about 722 to 481 B. C. Other data show that Meng Tzu, 372 to 289 B. C. used an Fe plow. Anthracite coal as fuel was used about 1100 A. D. Original Chinese method of Fe manufacture is described in an ancient technical book, "Meng Hsi Pi Tan." It corresponds to modern practice. A notable application of cast Fe for roofing is found in Tai Shan temple, built about 500 years ago and still in service. VSP (15b)

The Dillingen Works (L'Usine de Dilling) H. VAN HAM. *Revue Technique Luxembourgeoise*, Vol. 28, Jan.-Feb. 1936, pages 14-20. MANUFACTURERS' LITERATURE

Heat Exchanger

Bulletin No. 173 describes the Duriron heat exchanger which is available in the company's corrosion-resisting alloys—Duriron, Durichlor, Durimet, Durco Alloy Steel and Alcumite. Illustrated. Duriron Co., Dayton, O. (567)

Salt Bath Furnace

Although the advantages of molten salt baths have been recognized, they have not attained widespread use because of the shortcomings of furnace designs. The Ajax-Hultgren electrically heated salt bath was designed to meet the metallurgical requirements of liquid heat treating operations. Bulletin 103 lists some of the advantages of the furnace. Illustrated. Ajax Electric Co., Inc., Philadelphia, Pa. (568)

Kramer Alloy News

This publication is of interest to users of non-ferrous ingot metals. The importance of research is stressed in this special Foundrymen's convention number. H. Kramer & Co., Chicago, Ill. (569)

How to Bronze-Weld

This booklet contains a practical presentation of the fundamental theory and technique of bronze-welding and bronze-surfacing. The advantages of speed and economy are discussed, as well as the ability of bronze-welding to accomplish jobs which, according to the manufacturer, might otherwise be difficult or impossible, such as the joining of dissimilar metals. Linde Air Products Co., New York, N. Y. (570)

Dowmetal Data Book

A new edition of this book, containing especially significant accomplishments since the last data book, in the sections Available Forms and Shop Practice, has been published by The Dow Chemical Co., Midland, Mich. (571)

Aerocase

Booklet on this subject. Illustrations, curve charts, tables. American Cyanamid and Chemical Corp., New York, N. Y. (572)

Dolomite Refractories

This interesting pamphlet presents the case of Clinkered vs. Calcined Dolomite in the basic open-hearth steel furnace. Basic-Dolomite, Inc., Cleveland, O. (573)

Sixteen Sins of the Cleaning Room

Are listed in a circular for convenience in checking on cleaning rooms. Great Lakes Foundry Sand Co., Detroit, Mich. (574)

Metallurgy of Wire Manufacture

This paper contains valuable and interesting data and was presented by H. W. Graham, general metallurgist of Jones & Laughlin Steel Corp., Pittsburgh, Pa. (575)

Refractory Cement

Bulletin No. 317, describes Q-Chrome neutral-base refractory cement which was designed for severe-service duty. Quigley Company, Inc., New York, N. Y. (576)

Value of Draft Control

Bulletin No. L-125 is devoted to the above subject and points out the proper value of the furnace draft and this company's control which consists of a draft switch, a damper motor and a manual station. Illustrated. Shallcross Controls, Inc., Milwaukee, Wis. (577)

Lectrodryer

Bulletin DP discusses the Lectrodryer which was designed specifically for the drying of air, gases and certain vapors and liquids, using activated Alumina, a solid adsorbent. Illustrated. Pittsburgh Lectrodryer Corp., Pittsburgh, Pa. (578)

Industrial Furnaces

This catalog describes, illustrates and gives specifications for furnaces suitable for various applications. Mahr Manufacturing Co., Minneapolis, Minn. (579)

Special Atmospheres in the Heat Treatment and Razing of Metals

A reprint of the above article by C. L. West, Research Engineer, is offered by The Electric Furnace Co., Salem, O. (580)

Free-Cutting Phosphor Bronze—Nickel Silver

Information on outstanding characteristics and diversity of applications of these metals is contained in an illustrated leaflet. Other products of the company are also listed. The Riverside Metal Company, Riverside, N. J. (581)

Seamless Flexible Tubing

Bulletin 1936-1 contains the statement that American tubing is the most reliable type of flexible metal conveyor obtainable for services where absolute, 100 per cent tightness is essential. American Brass Company, Waterbury, Conn. (582)

Sicromo Steel

High temperature data sheets containing full information on this steel have been issued by The Timken Steel & Tube Co., Canton, O. (583)

Vanadium Facts

Another issue of this publication contains accounts of progress and performance in the field of alloy steels. Vanadium Corp. of America, New York, N. Y. (584)

Research Puts the Diatom to Work

This booklet discusses the history of the diatom from which Celite is made. The four main industrial services of Celite: high temperature insulation, a filter aid, mineral filler and workability agent in concrete are described. Illustrated. Johns-Manville, New York, N. Y. (585)

Granite City HS Grades 1 and 2

Information concerning the Granite City manganese high tensile steels can be obtained from the Granite City Steel Co., Granite City, Ill. (586)

MoTung High Speed Steel

An illustrated booklet devoted to the above, contains information under these divisions: working and treatment, surface protection, high heat temperatures, drawing temperatures, effect of treatment, etc. An index is included. Universal Steel Co., Bridgeville, Pa., and Cyclops Steel Co., Titusville, Pa. (587)

Electromet Review

This publication, whose purpose is to bring "News and Views of Alloy Steels and Irons" to the reader, contains interesting items. Electro Metallurgical Co., New York, N. Y. (588)

Electric Welding Products

Catalog No. 101 contains information on welding rods (recommended uses for the different types, physical properties, welding procedure, etc.); miscellaneous apparatus, and Wilson arc welding machines. Air Reduction Sales Co., New York, N. Y. (589)

Arc Welding

A book "Automatic Arc Welding by the Electronic Tornado" gives a full explanation of this system of automatic carbon arc welding. Lincoln Electric Co., Cleveland, O. (590)

Sonittep Products

This booklet discusses heat loss and its control. The advantage of Sonittep insulating cement and its uses are listed. Instructions for its application are included. Graphs. George F. Pettinos, Inc., Philadelphia, Pa. (591)

Sintered Carbides

This new booklet contains quite complete information on Firthite cutting tools which, the manufacturer claims, increase and better production and reduce tool cost. Firth-Sterling Steel Company, McKeesport, Pa. (592)

Centrifugal Castings

Bulletin C-2 is devoted to these castings which are available in the same analyses as the stationary-cast range of heat and corrosion resistant alloys which they supplement. Michigan Steel Casting Co., Detroit, Mich. (593)

Flex-Arc Rays

Data bulletins containing information on arc welding are published by the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa. (594)

Refractories and Crucibles

An attractive book gives an abundance of information on super-refractories, high temperature cements, Tercod crucibles and Electroloys. Electro Refractories & Alloys Corp., Buffalo, N. Y. (595)

Atmospheric Burners

Bulletin 133-3 is concerned with the Sincro Venturi Atmospheric Burners and Immersion Burners. Illustrated. Philadelphia Drying Machinery Co., Philadelphia, Pa. (596)

Modern Metal Treatment

A colorful pamphlet lists the R & H chemicals available for heat-treating, electroplating and for cleaning metals. E. I. du Pont de Nemours & Co., Inc., Wilmington, Del. (597)

Wheelabrator Tum-Blast Cleaner

This cleaner, which it is claimed sets the highest standard of efficiency ever attained in an abrasive cleaning machine is a combination of the Tum-Blast Cleaner and the Wheelabrator. Book 111 is devoted to it. American Foundry Equipment Co., Mishawaka, Ind. (598)

Application of Heat to Core baking

A profusely illustrated booklet containing information resulting from research on the subject has been published by the American Gas Association, New York, N. Y. (599)

Aluminum Flux

A pamphlet entitled "Look into the Ladle" describes how this flux supplies the chemical and metallurgical needs in the melting of aluminum. The Maluminum Co., Indianapolis, Ind. (600)

MANUFACTURERS' LITERATURE

Micromax Electric Control

A complete control system for regulating input in proportion to demand is the subject of Catalog N-OOA. It is based on a simple potentiometer balance and consists of three parts, Micromax control instrument, relay detector and valve mechanism. Illustrated. Leeds & Northrup Co., Philadelphia, Pa. (601)

Cupola Blowing

Motorblowers avoid the loss of air and coke by accurately controlling the weight of air supplied to the cupola. The principles of operation of this automatic air-weight control are described and illustrated in a bulletin issued by Ingersoll-Rand, New York, N. Y. (602)

Indicating and Recording for Rolling Mills

United Pressuremeter indicates rolling pressures at as many points as is advantageous and records at still another location. The manufacturer claims that it is rugged, sensitive and easily adjustable. Illustrated booklet. United Engineering and Foundry Co., Pittsburgh, Pa. (603)

Convected Air Tempering Furnaces Heated by Gas

Bulletin No. 40 concerns these furnaces which use the principle of mechanical convection to the maximum by incorporating in the design a patented rotary fan to drive the heated air downward with pressure and great velocity, in and around through the parts to be processed. Despatch Oven Company, Minneapolis, Minn. (604)

Pyrometers

Alnor pyrometers for molten nonferrous metal service are described in Bulletin No. 1724. Suggested applications for the different types are included. Illustrated. Illinois Testing Laboratories, Inc., Chicago, Ill. (605)

Silica Firestone

Buckeye silica firestone linings are natural products. A selected Split Rock is used in its manufacture which, because of a combination of its peculiar granular structure and chemical analysis, coupled with the colloidal silica bond, has an extraordinary resistance to combined fire and abrasion, according to this company. Well illustrated bulletin, No. 15A, featuring history, technology, splitting and working the stone and refractory uses. Cleveland Quarries Co., Cleveland, O. (606)

Spencer Turbo-Compressors

This bulletin which has illustrations of the complete range of sizes of this equipment also contains: "Midget" Turbo for individual mounting, a single-stage line which effects new economies and Gas-Tight Turbos for acid and explosive gases. Spencer-Turbine Company, Hartford, Conn. (607)

Armco H.T.-50

An illustrated folder devoted to the above alloy steel contains data on the average physical properties, corrosion resistance and forming and welding qualities. American Rolling Mill Co., Middletown, O. (608)

Radium for Industrial Radiography

This article written by R. A. Gezelius and C. W. Briggs, containing interesting and important information on the subject, is published in handy booklet form. Radon Company, Inc., New York, N. Y. (609)

What Scientists Say of Leitz Ultropak

Bulletin No. 17 describes the personal experiences and applications to which Ultropak has been placed by scientific workers in various fields. Profusely illustrated. E. Leitz, Inc., New York, N. Y. (610)

Polishing Machines

A portable model and a floor model of these new metallographic machines are described and illustrated in a pamphlet from Eberbach & Son, Co., Inc., Ann Arbor, Mich. (611)

Cor-Ten and Man-Ten

Pamphlet describing high-tensile steels developed to meet the need of the transportation industry. United States Steel Corp., Pittsburgh, Pa. (612)

Rolled Manganese Products

The Rol-Man products have a chemical analysis which precisely follows the original Hadfield formula which assures toughness, strength and wear resistance in manganese steel. According to this manufacturer, their process of hot rolling and discarding of ends produces a steel with purity, strength, tough hardness, ductility and wear resisting qualities double those of cast manganese steel. An alphabetical index of various products which they have made or can produce in forged, stamped or rolled manganese steel is included. Manganese Steel Forge Co., Philadelphia, Pa. (613)

New Light Hoist

Bulletin H-1 describes the Zip Lift line of hoists which are designed for use where loads must be moved fast and at low cost. Complicated wiring has been eliminated so that for hook, trolley or jib crane service the hoist needs only to be hooked up and plugged in. Harnischfeger Corp., Milwaukee, Wis. (614)

Thermalloy Castings

Bulletin 101 contains information on Ni-Cr castings for heat and corrosion resistance which are X-ray inspected. Electro Alloys Co., Elyria, Ohio. (615)

Liquitol

Bulletin A1-16-A deals with the use of Liquitol for iron and steel castings and ingots. Alpha-Lux Co., Inc., New York, N. Y. (616)

Chapmanizing

A pamphlet devoted to Chapmanizing, which is a process of hardening low-carbon steel, compares it to nitriding and carburizing. The Chapman Valve Mfg. Co., Indian Orchard, Mass. (617)

High Temperature Resistance Alloys

Kanthal alloys, made of chromium, aluminum, cobalt and iron, in three grades for different temperatures, are discussed in a leaflet offered by The C. O. Jelliff Mfg. Corp., Southport, Conn. (618)

A. W. 70-90

This bulletin describes the new high-strength "70-90" steel in sheets and plates. An article on the engineering aspect of high-strength sheet steels is included. Alan Wood Steel Co., Conshohocken, Pa. (619)

Bearing Security

This leaflet lists the four essentials of a bearing metal and claims that Ajax Bull Bearing alloy embodies them. Ajax Metal Co., Philadelphia, Pa. (620)

Properties of OFHC Copper

An attractive booklet contains reprints of three papers relating to the above subject. Photographs, diagrams and photomicrographs are used to illustrate them. United States Metals Refining Co., New York, N. Y. (621)

Zinc Alloy Die Castings

A technical booklet tells the story of the development of the "Zamak" alloys. Tables and illustrations. New Jersey Zinc Co., New York, N. Y. (622)

Silico-Manganese Spring Steel

Extreme care is taken in processing this steel to avoid imperfections, in rolling to obtain cold-shearing qualities and in controlling the uniformity of the structure to insure both high inherent fatigue resistance and uniform heat treating characteristics, according to the manufacturer. Illustrated. Bethlehem Steel Co., Bethlehem, Pa. (623)

Welding Rods

Hard-facing welding rods Nos. 459 and 217 are the subjects of an illustrated brochure. Hard surfacing can be done with these rods, either electrically or by the oxy-acetylene process to the great majority of ferrous welding parts. American Manganese Steel Co., Chicago Heights, Ill. (624)

Bronze Bearing Service

A bearing counselor service has been established by this company, whereby engineers and metallurgists study the customer's application and offer advice as to what type of bearing will be most satisfactory. This leaflet contains information regarding the service. Johnson Bronze Co., New Castle, Pa. (625)

Alloy Steels

A colorful folder devoted to these steels lists some of the advantages to be obtained by their use. A list of the more commonly used grades that are in constant demand is included. Bliss & Laughlin, Inc., Harvey, Ill. (626)

Hardness Tester

Catalog No. 10 is devoted to the "Rockwell" hardness tester which was designed for use on all metals in the laboratory or the shop. The principles of the tester, which is a combined press, weighing machine and micrometer, are described and illustrated. Wilson Mechanical Instrument Co., New York, N. Y. (627)

Gas Fired Furnace

The manufacturer of the gas fired Lindberg Cyclone furnace for heating at temperatures from 250 deg F. to 1400 deg. F. claims that the heating rate is remarkably fast, and either open or extremely dense charges are handled with equal facility. The principle of the furnace is described in Bulletin 51. Illustrations. Lindberg Engineering Co., Chicago, Ill. (628)

Inhibitor

Grasselli 3 inhibitor for efficient, economical pickling is the subject of a booklet of The Grasselli Chemical Co., Inc., Cleveland, O. (629)

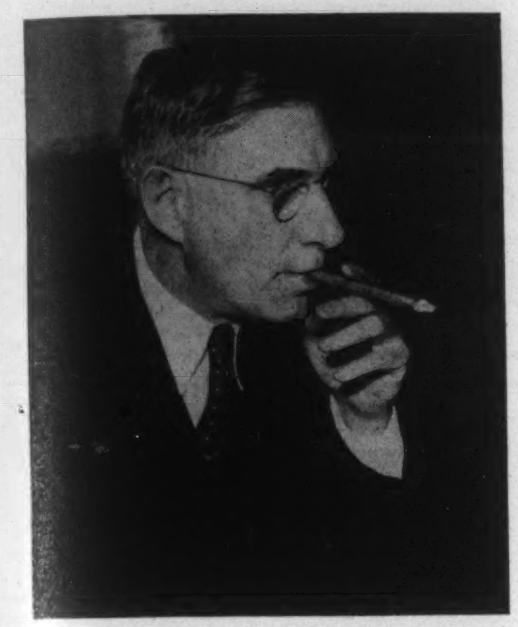
Mallory Elkon

Looseleaf catalog containing engineering data with descriptions, illustrations and recommendations for the selection of electrical contacts for all types of service. P. R. Mallory & Co., Inc., Indianapolis, Ind. (630)

CURRENT NEWS ITEMS

Wetherill Medal to A. L. Marsh

Several honors were bestowed by the Franklin Institute of Philadelphia at special exercises on May 20 in the award of medals.



A. L. Marsh

Prominent among these was the bestowal of the John Price Wetherill Medal on Albert L. Marsh, president of the Hoskins Mfg. Co., Detroit, makers of electric furnaces, pyrometers and resistance wire. Mr. Marsh received this distinguished award "in consideration of the contribution of a material which has proved of extreme importance to the electrical industries." This material is "Chromel," developed and perfected by Mr. Marsh after years of intensive experimentation and research. The medal was founded in 1925 by the family of Mr. Wetherill and awarded for "discovery or invention in physical sciences or for new and important combinations of principles or methods already known."

Other Awards

The Edward Longstreth Medal, founded in 1890 by the late Edward Longstreth of Philadelphia, retired member of the Baldwin Locomotive Works, for the encouragement of invention, was awarded to Dr. Alfred V. de Forest, president of the Magnaflux Corp., New York, and associate professor in the Massachusetts Institute of Technology. It was also awarded to Elmer A. Sperry, Jr., vice president, Sperry Products, Inc., Brooklyn.

The Franklin Medal, founded in 1914 by Samuel Insull of Chicago, a long-time member and friend of the Institute, was bestowed on Dr. Frank B. Jewett, vice president of the American Telephone and Telegraph Co., and president of the Bell Telephone Laboratories. This medal was also awarded to Dr. Charles F. Kettering, vice president and director of General Motors Corp., "in recognition of his significant and timely contributions to the science of automotive engineering."

New Officers of the Foundrymen

James L. Wick, Jr., president and general manager, Falcon Bronze Co., Youngstown, O., was elected president of the American Foundrymen's Association at the annual business meeting of that organization held during the convention last month in Detroit. This honor comes to Mr. Wick after a long career of distinguished service to the foundry industry and in the affairs of the A.F.A. For many years, he has been active in the cost work of the association and has taken an active part in the affairs of the nonferrous division. Prior to his election to the presidency, he was vice president and chairman of the divisional activities correlation committee.

Hyman Bornstein, director, testing and research laboratories, Deere & Co., Moline, Ill., was elected vice president of the American Foundrymen's Association at the same meeting. Mr. Bornstein well merits this recognition for he has been one of the most active members of A.F.A. for many years. He has been active in committee work, serving at various times as chairman of the committee on gray iron castings, member of the committee on specifications for malleable castings, member of the committee advisory to liquid shrinkage investigation of metals advisory to the Bureau of Standards, member ferrous metals advisory committee to the Bureau of Standards, member of committee on metallography and many others. At present, he is general chairman, Gray Iron Division of A.F.A., and chairman, Alloy Cast Iron Committee. He also served as a director of A.F.A. from 1932 to 1935. Mr. Bornstein has had a distinguished career in the metallurgical field and is recognized both nationally and internationally as a leading authority on cast iron.

For directors the following were selected:

Dan M. Avey, editor of "The Foundry," who has just completed two successful terms as president. This is his second term as a director, his first term being 1931 until his election to the vice presidency in 1933; Carl C. Gibbs, president, National Malleable & Steel Castings Co., Cleveland; Marshall Post, vice president, Birdsboro Steel Foundry & Machine Co., Birdsboro, Pa.; James R. Allan, for 25 years connected in various capacities with the International Harvester Co., Chicago, and Lester N. Shannon, vice president, Stockham Pipe Fittings Co., Birmingham, Ala.

Testing Society's Annual Meeting

According to announcements of the secretary of the American Society for Testing Materials, a large number of technical papers and reports are scheduled for presentation during the 1936 annual meeting at Chalfonte-Haddon Hall, Atlantic City, June 29 to July 3. Some 20 sessions have been scheduled so as to assure adequate time for presentation and discussion of the papers.

The sessions do not begin until Tuesday, June 30, Monday being given over to numerous committee meetings. One of the features of the week is the symposium on X-Ray Crystallography and Radiography sponsored by Committee E-4 on Metallography through its sub-committee VI. This will take four sessions at which 12 papers, 6 on radiography and 6 on diffraction, will be presented by leading authorities, under the direction of Dr. R. F. Mehl, Carnegie Institute of Technology.

Other features include several papers on various phases of spectrographic analysis, with separate sessions devoted to non-ferrous metals, wire corrosion, fatigue and the effect of temperature on metals.

At the opening session on Tuesday, June 30, Dr. H. C. Parmelee, editor of *Engineering and Mining Journal*, will deliver an address on "Chemical Engineering and Its Relationship to the Work of the A.S.T.M." The president of the society, H. S. Vassar, will also present his annual address at this session.

The tenth Edgar Marburg lecture will be delivered Wedneday afternoon, July 1, by Dr. Arthur L. Day, director, geophysical laboratory, Carnegie Institute of Washington. His subject is "Developing American Glass" in which work he has played a leading part. At the same session the Charles B. Dudley Medal will be awarded to H. C. Mann, research engineer, Watertown Arsenal, for his paper on "The Relation Between the Tension Static and Dynamic Tests," presented at the 1935 annual meeting.

A. W. Demmler Promoted

A. W. Demmler has recently been appointed metallurgical engineer in the research and development department of the **Vanadium Corp. of America.** He continues his office in Bridgeville, Pa., where he has been located in various capacities for the past 13 years.

Following graduation from Pennsylvania State College, Mr. Demmler obtained his M.S. from Massachusetts Institute of Technology and continued his graduate studies at the Royal Technical University of Stockholm, Sweden as fellow in electrometallurgy of the American-Scandinavian Foundation. Subsequently, he taught this subject at Pennsylvania State College and then entered the metallurgical department of United Alloy Steel Corp. from which he came to his present connection.

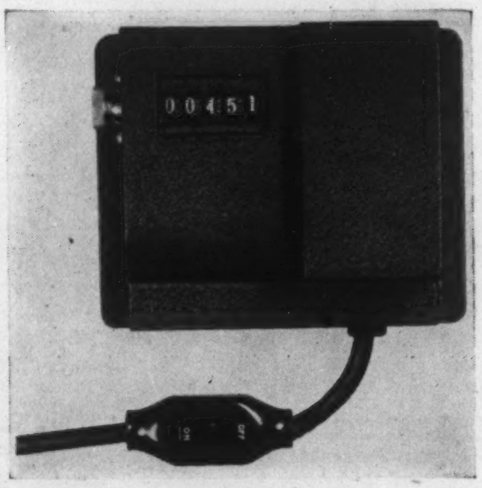
George P. Halliwell, formerly assistant professor of metallurgy at Carnegie Institute of Technology, has been appointed director of research at **H. Kramer & Co.**, Chicago, refiners of non-ferrous metal scrap and producers of brass ingots and non-ferrous alloys.

NEW EQUIPMENT AND MATERIALS

A Timing Instrument

The "Tymeter" is the result of many years of close association in the production of timing instruments for the industrial field and is the culmination of what is most accurate and applicable for use in the industries from a composite experience gained through intimate contact with their timing problems. Especially is the tymeter invaluable in precision timing, says the M. J. Stillman Co., 116 So. Michigan Ave., Chicago.

It is constructed to withstand constant and severe usage and is guaranteed for 5 years. Its application is wide and varied, but chiefly it will readily prove its worth in timing of industrial operations, setting piece work rates, establishing premium system, cost determination of manual or mechanical operations, viscosity testing, laboratory and research and in fact is claimed applicable in the entire gamut of industrial timing necessities where indisputable accuracy is a factor.



The tymeter operates with a sturdy synchronous motor specially constructed for this type of work and its power is obtained from 60-cycle, 110-volt alternating current. The case is of die cast aluminum with a black crackle finish. For the convenience of the operator, the starting and stopping switch will permit time to be taken out by stopping the machine and again starting without going back to zero. The knob on the left hand side is used for returning all figures to zero by pulling same out and turning ahead until all figures are cleared. The knob will then drop into a locked position.

Where it is desired to entirely obviate the human element in starting and stopping the tymeter, it is possible to furnish photo-electric-cell equipment in connection. This of course will require additional charges and estimates will be furnished on request after submission of the problem.

The instrument is furnished in three models. Model "T" operates in seconds and tenths of seconds and is shown in the illustration in actual size. The extreme right hand wheel registers tenths of seconds and the four remaining wheels register seconds up to and including 9999.9 sec.

Model "D" operates in the decimal system with the extreme right hand wheel registering hundredths of minutes, the second wheel from the right registering tenths of minutes and the remaining three wheels registering minutes up to and including 999.99 min. Model "H" operates in seconds and hundreths of seconds and is used for very fast and precise work and is applicable for races where records are to be established. The extreme right hand wheel registers hundreths of seconds and the remaining four wheels register seconds up to and including 9999.99 sec. It supersedes all other types of timing mechanism which are spring wound due to its accuracy and its use will quickly convince the operator of its superiority. All standard models are furnished for 60-cycle, 110-volt alternating current only. For 220-volt 60-cycle or for 50-cycle current, special models can be furnished at a small additional charge.

New High Temperature Steel

The Timken Steel & Tube Co., Canton, O., has announced a new steel designated as "Silmo," especially designed for applications where an economical combination of high-temperature strength and oxidation resistance is required. In the temperature range of 1000-1200 deg. F. the new steel is claimed to have about twice the strength of carbon steel and its oxidation resistance compares favorably with that of 4 to 6 per cent Cr-Mo steel.

This new steel may be used to replace carbon steel where greater safety is required and as a substitute for the standard carbon-molybdenum steel where oxidizing conditions are encountered. Indicated uses lie in the field of cracking furnace tubes, pipe still heater tubes, high-pressure boiler and superheater tubes, and tubing used in the manufacture of air heating equipment.

Complete physical data covering high-temperature tensile properties, Charpy value at elevated temperatures, heat embrittlement tests, creep strength, temperature-stress embrittlement tests, stability, and corrosion and oxidation resistance, together with curves showing the creep strength at various temperatures and the relation between creep strength and rate of creep at 800, 1000 and 1200 deg. F. are presented in a series of six looseleaf pages available on request to the Timken company.

Rubber Latex as a Protective Coating

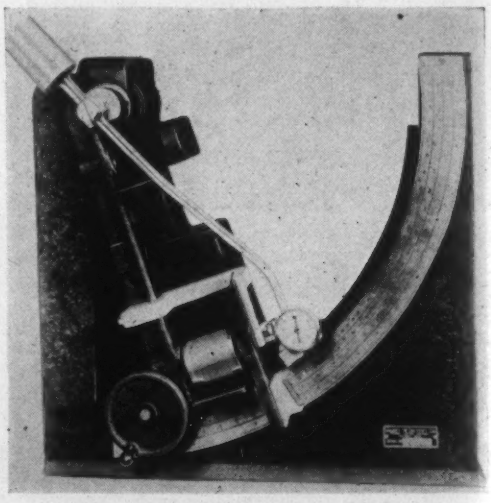
A new commercial use for rubber latex as a protective coating, easily applied and readily removed, for automobile bumpers, fenders and other articles to be shipped or stored, is announced by R. W. Albright, general manager of American Anode, Inc., Akron, Ohio. The new compounded material, known as "Protex," is now being employed by bumper and automotive manufacturers to cover metal parts. In some instances even entire automobiles have been coated for export shipment from the factory to the consumer.

Refrigerators and other articles with polished surfaces have also been successfully coated with "Protex" giving protection against abrasion, bumps and corrosion during transportation and storage. Outstanding properties are its ease of application, flexibility and resistance to chemical action, according to Anode company officials.

Deformation and Resilience Accessory for Sand Strength Machine

The "Deformation Tester" is a most useful accessory for the Universal Sand Strength Machine in that it adds materially to the value of the compression strength test, says the Harry W. Dietert Co., Detroit. The deformation test readings are multiplied by the compression test reading to obtain the sand resilience value which figure is used to determine whether the sand has good life or whether it is "short" and "brittle." Its net weight is 5 lbs., shipping weight, 10 lbs., length overall, 24 in., and capacity, 0 to 0.100 in.

The deformation test accessory consists of an aluminum arm pivoted on ground and sealed ball bearings at the fulcrum point of the pusher arm and weight of the strength machine. A special dial indicator, protected from dust, is mounted on the free end of the deformation tester arm. The stem of the indicator bears against the stud of the compression test head, while the body of the indicator is connected to the pusher arm of the strength machine through an automatic releasing arm which makes it possible to measure the amount that the sand specimen decreases in length or deforms at the instant that the sand specimen breaks. The maximum reading of the deformation indicator is shown by a red maximum reading hand.

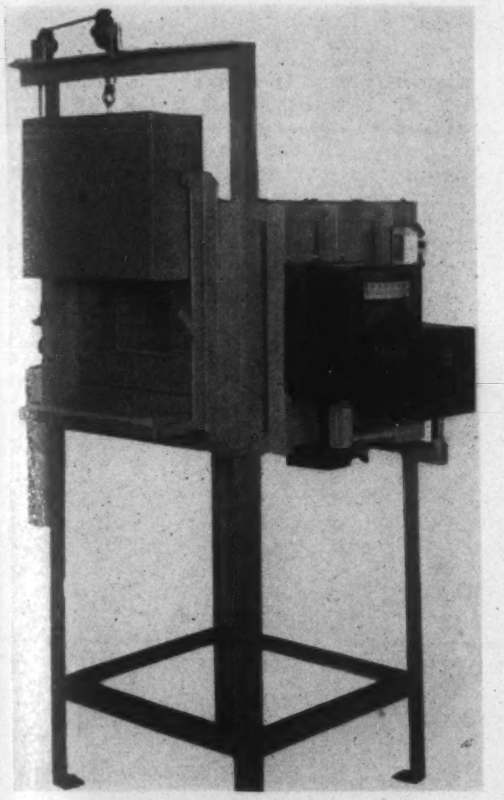


The deformation test requires very little extra effort on the part of the operator in that it is made at the same time that the compression test is made. The operator moves the arm of the deformation indicator to its lowest position and sets the reading hand of the indicator to zero. Molding sand, like other materials, may possess a satisfactory strength but the strength possessed is considerably limited, due to a property which may be termed "deformation." For example, when a material is brittle, then its load carrying power is very limited. Molding sand may become "short" or "brittle" though the strength is satisfactory.

A factor termed "Sand Resilience" takes into consideration both the strength and the deformation, and this adds much to the green sand strength test. Sand resilience indicates the amount of work required to break the sand. It is calculated by multiplying the green compression strength reading by the reading of the Deformation Indicator.

High Temperature Muffle Furnaces

To its line of industrial electric heat treating equipments, H. O. Swoboda, Inc., Pittsburgh, announces the recent addition of "FALCON" high temperature electric muffle furnaces. This furnace is suitable for operating temperatures up to 2300 deg. F. and is equipped with high temperature metallic heating elements mounted in the hearth, roof, side walls and rear of the furnace. The elements are of the wound type substantially supported in grooved refractories. The refractories are reversible for forming muffle chambers, or separate muffles can be supplied. Inside dimensions of the muffle are 9 in. wide x 6 in. high x 13 in. deep. Capacity of furnace, 6 kw. The refractories are backed by three layers of block type high temperature insulation.



The entire chamber together with heat insulation is enclosed in sheet metal casing. A steel frame door together with refractory charging shelf is provided on the furnace. The door is raised and lowered by means of hand cable and side counterweight. The door is provided with the same high temperature insulation as the furnace chamber. All connections for the heating elements are entirely enclosed within the furnace casing at the rear, so that no live current carrying parts are exposed.

Automatic temperature control equipment is mounted on and connected to the furnace. Furnaces are available in various chamber sizes and capacities as well as for 110, 220 or 440 volts, single or 3-phase; type of control optional.

A New Salt Bath Furnace

The advantages of molten salt baths compared with other types of heat treating furnaces have long been recognized by metallurgists. These inherent advantages, such as the prevention of scaling and oxidation of the work, more rapid heating, etc., are cost reducing factors which lend themselves to most heat treating operations. Moreover, the concentrated efforts and scientific research of salt manufacturers in the past decade have made available a large variety of salt mixtures designed for every form of liquid heat treating operation, such as case-hardening, re-heating, annealing, tempering, etc. But, in spite of these inherent properties, molten salt baths have not attained the wide-spread use they so justly deserve. This is claimed as entirely due to the shortcomings of furnace designs. Fuel-fired pot furnaces, because they are externally fired, operate at an extremely low efficiency and entail very high pot maintenance costs. These and other limitations of existing pot furnace designs led Ajax engineers to investigate the possibilities of developing an electrically heated salt bath, specifically designed to meet the severe metallurgical requirements of liquid heat treating operations encountered in cyaniding, hardening, annealing, etc.

The "Ajax-Hultgren Salt Bath Furnace" is the result of this pioneer work. Results being obtained in commercial operation justify the claim of the Ajax Electric Co., Philadelphia, that this salt bath furnace has not only eliminated definite disadvantages in other furnaces but possesses advantages hitherto unknown. A complete description of this furnace is found in the first article in this issue.

"Metal-Bord"

The American Nickeloid Co., Peru, Ill., announces a new development of considerable importance in the metal field. It is the replacement of metal volume and weight by a non-metallic substance. This is accomplished by adhering thin sheets of pre-finished metal to cardboard or other backing material. The metallic appearance of the sheet is retained, but the body of the sheet is largely the non-metallic backing. The adhering cement will remain plastic and has, therefore, practically permanent adherence. It remains flexible.

The advantage of such a composited material lies in the lower cost and saving in weight, which are two important factors in most products. Any thickness of metal can be used and composited to just about any type and thickness of backing. This new product is called "Metal-Bord."

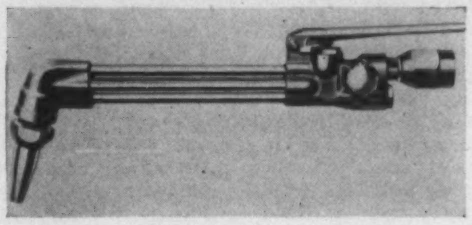
An Oxy-Acetylene Cutting Attachment

A new oxy-acetylene cutting attachment known as the "Oxweld Type CW-22" has been announced recently by The Linde Air Products Co., 30 East 42nd St., New York. This cutting attachment incorporates features of design and possesses a range and quality of performance, which permit it to handle light sheet metal as well as all but the heaviest work at speeds and efficiency equal to those of the full size cutting blowpipe. The attachment operates on low-pressure or medium-pressure acetylene, with equally satisfactory results. Severe field tests have proved its capacity, stability and endurance under all conditions.

The Type CW-22 cutting attachment can be used on either the Oxweld Type W-17 or W-22 welding blowpipe handle, thereby greatly extending the utility of these two popular blowpipes.

Sturdy, smooth operation at all times and all pressures is given by the new streamline injector and by the improved type cutting valve, with removable seat, centralized under the cutting lever. The mixed gas passage is formed by three Ambrac tubes. The length, and four 90-deg. changes of direction, afforded by this type of construction give exceptional flashback resistance. The body and head of the CW-22 are designed to combine strength and lightness, the body being of pressure-forged bronze while the head is a manganese bronze forging.

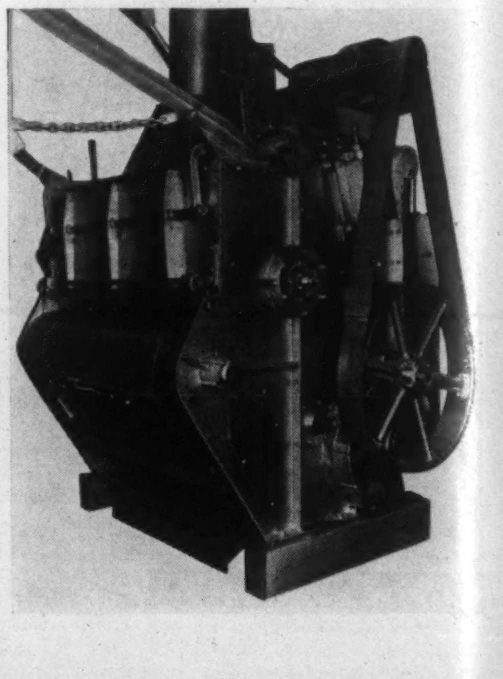


A Small Wheelabrator Tum-Blast

A new small "Wheelabrator" unit, designed especially for use in foundries, shops and plants having a limited production, is announced by The American Foundry Equipment Co., 555 Byrkit Street, Mishawaka, Ind. The new wheelabrator unit is installed in a new size tum-blast mill. While smaller in size, this mill has all the desirable features which are responsible for the international popularity of the larger Wheelabrator Tum-Blast.

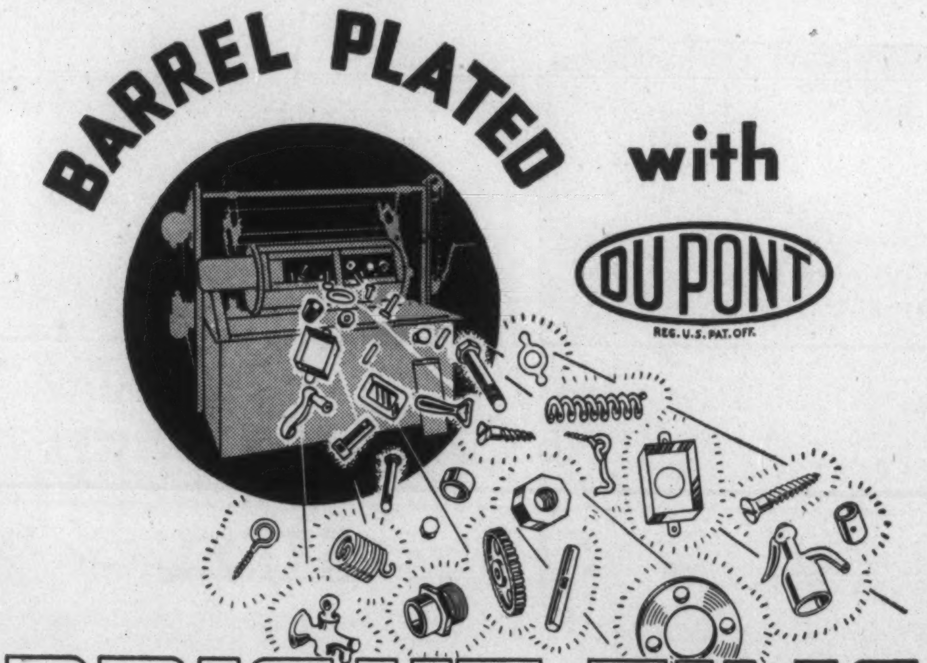
Material to be cleaned is loaded directly onto the apron conveyor. When the mechanism is set in operation, the action of the conveyor apron cascades the individual castings, over and over, directly under the blasting area, assuring complete coverage at all times. In unloading, the movement of the conveyor is reversed, allowing cleaned products to spill into waiting receptacles under the machine.

Centrifugal force replaces compressed air as a driving agent in whipping abrasive onto the work to be cleaned in the wheelabrator. Abrasive is fed by gravity from an overhead storage bin in the center of the wheelabrator. After blasting it drops through holes in the conveyor plates into a hopper below where refuse is automatically screened out. Cleaned abrasive drops into the boot of a bucket elevator and is lifted to an overhead storage hopper for re-use. Steel grit or shot may be used over and over. Dust is carried out of the tum-blast by the American dustube collector operated in conjunction with the machine. The abrasive cycle used in wheelabrating is constant until the machine is shut off for loading or unloading.



Many new developments are incorporated in the construction of this 27 x 36 in. wheelabrator unit. The door is counterweighted for easy operation. It swings up and provides an unobstructed opening for loading and unloading. It is completely equipped with dust seals. The apron conveyor can be provided with either overlap or flat type slats, depending on the type of material to be cleaned. Both slats are furnished with heavy-duty reinforcing channels.

Having an operating load capacity of 5 cu. ft., the 27 x 36 in. Wheelabrator Tum-Blast answers the need of manufacturers with a limited production for automatic cleaning equipment which is both economical in operation and maintenance.



BARREL PLATED with DU PONT REG. U.S. PAT. OFF.

BRIGHT ZINC

NUTS and bolts, hasps, hooks, springs, machined parts, stampings . . . and other steel parts are now barrel-plated commercially with du Pont Bright Zinc. Bright dipping unnecessary, although extra high luster can be obtained after plating by a bright dip in bulk and in baskets. Excellent results. Low costs, for no expensive addition agents are used. Solution is self-maintaining except for dragout. No metal salt replenishment.

This *dependable* Bright Zinc process is giving consistently good commercial results in barrel plating, full- and semi-automatic units. It is by far the easiest plating solution to control.

E. I. DU PONT DE NEMOURS & COMPANY, Inc.
Wilmington, Delaware

A Hydrogen Brazing Furnace

An electrically-operated hydrogen brazing furnace designed especially for the tipping of sintered carbide cutting tools is announced by the Firthite Division of the Firth-Sterling Steel Co., McKeesport, Pa. Known as the "Firth Braze-Rite Furnace," it provides for a simplified and improved method of brazing carbide blanks to steel shanks insuring a positive, permanent braze. With the furnace, tools of a wide variety can be brazed in much less time than has heretofore been required since heat is localized at the end of the tool on which the carbide blank is to be mounted, eliminating the necessity of heating the entire shank.

The furnace is provided with two separate mufflers, each of 2-ii. capacity. Those mufflers are made of a high heat-resisting alloy, developed to withstand brazing temperatures and which, in turn, will offer exceptionally long life. Tools varying in size from small bits up to those having 1½-in. sq. shanks can be accommodated. Either 110-220 volts A.C. or D.C. can be used for operation. When A.C. is employed a tap transformer is supplied and, when D.C. is used, the control is through a rheostat. A direct-reading pyrometer is mounted at the rear of the furnace.

The furnace can be brought up to brazing temperature in a very few minutes. On the other hand, when the furnace is to be shut down, it is not necessary to make gradual current reductions as with former type hydrogen furnaces. This feature makes the furnace exceptionally suited for the brazing of small quantities of tools, in addition to continuous operation for larger quantities.

Brazing is carried out in a hydrogen atmosphere to prevent oxidation of the carbide tip and shanks, as well as the brazing material. Hydrogen is admitted through openings at the rear of each muffle. The amount of hydrogen is controlled by valves located at the rear of the furnace. A manifold is provided for connection of the hydrogen supply.

Economical operation of the furnace is claimed an outstanding feature since very little current is required to maintain a correct brazing temperature. A single tank of hydrogen will provide for several days' operation under normal use. The muffles, which can be quickly interchanged, will offer several hundred hours' life under ordinary conditions. The heating elements, likewise, will provide exceptionally long use.

Complete tools required for brazing are furnished, including tongs, shears, scraper and tip presser. In addition, a quantity of Firth Braze-Rite flux and copper is supplied, suitable for the brazing of a large quantity of tools.

A metal-top table is furnished optionally, although the furnace can be mounted on a bench if so desired. The table when furnished measures 21 x 21 in.

– a uniform distribution of heat

Armstrong's N-20 Brick makes an important contribution to the efficiency of this Lee Wilson Annealing Cover

HERE'S a new annealing cover that has attracted the attention of production men throughout the heat treating field. It's made by Lee Wilson Engineering Co. of Cleveland, Ohio, for annealing sheets, coils, or tin plate.

Vertical tube design and Armstrong's N-20 Insulating Brick are the reasons for its efficiency, according to Mr. Wilson. They make possible larger hourly production, lower fuel costs, and "a more accurate and efficient distribution of heat to the charge—."

Today, more and more furnace builders are using Armstrong's High Temperature Insulation in their equipment. In addition to Armstrong's N-20 Insulating Brick, the Armstrong Line includes insulating brick and insulating fire brick for a complete range of temperatures and uses. We'd like to send you descriptive literature and samples of these efficient brick. Just write Armstrong Cork Products Co., Building Materials Division, 982 Concord St., Lancaster, Pa.

LEE WILSON ANNEALING COVER *of vertical tube design which makes possible even heating throughout the charge. Note the use of Armstrong's N-20 Insulating Brick (shown in diagrams) to assure this uniform temperature and low fuel cost. The fuel consumption per ton of sheets "ranges from 750 cu. ft. of natural gas per ton for low temperature annealing to 1250 cu. ft. for high temperature annealing."*

1. ORE CONCENTRATION

JOHN ATTWOOD, SECTION EDITOR

Mining Revival at Granya—Research on Ore Treatment Brightens Outlook. G. B. O'Malley. *Chemical Engineering & Mining Review,* Vol. 28, Feb. 8, 1936, pages 144-146. By an extension of the present plant (battery crushing and tabling treatment) to include grinding and amalgamation or straking of the concentrates and cyanidation of the table tailings an immediate recovery of 75% of the Au can be made. Direct cyanidation of the ore at —200 mesh (without roasting) yields 90% of the Au with a cyanide consumption of 5 lbs., a figure varying with the Cu content. It may be possible to eliminate the roasting operation. WHB (1)

■ 1a. Crushing, Grinding & Plant Handling ■

Size of Gold Grains in Copper Ore (3rd International Mines, Urals) S. I. Mitrofanov. *Tzvetnuie Metallui,* No. 4, May 1935, pages 54-55. In dressing Cu-Zn ores of the Mines the sands from classifiers contain grains of Au up to 0.5 mm. in largest dimension, and in the tailings up to 0.1 mm. Finer Au particles are also found in the concentrates. Suggests that Au bearing materials at various stages of ore concentration may be removed, that part of the Au from tailings may be removed mechanically, and finer Au particles by additional flotation operation. BND (1a)

The Theory of Crushing. Fred C. Bond. *Mines Magazine,* Vol. 25, June 1935, pages 11-13, 30. The lack of a complete exposition of the theory which governs crushing and grinding is pointed out and a mathematical approach is attempted. WH (1a)

■ 1c. Flotation ■

Principles of Flotation, IV—An Experimental Study of Influence of Sodium Sulfide, Alkalis and Copper Sulfate on Effect of Xanthates at Mineral Surfaces. Ian William Wark & Alwyn Birchmore Cox. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 659, Jan. 1936, 20 pages. The influence of Na_2S on contact induced by xanthate between air bubble and the minerals anglesite, cerussite, galena, sphalerite, pyrite, chalcopyrite, bornite, covellite and chalcocite was investigated. Na_2S is a depressant for the sulphide minerals. Concentration of Na_2S necessary to prevent contact is a function of pH value. The (HS^-) ion is the effective depressant and there is a critical value for each mineral. This value is not greatly influenced by the xanthate concentration. Cu_2SO_4 influences the effect of Na_2S on galena and chalcopyrite, probably removing it from solution as a precipitate of CuS. Cu_2SO_4 must be stoichiometrically in excess of the sulphide if it is to activate sphalerite. The combined influence of Cu_2SO_4 and Na_2S on pyrite is exceedingly complex. The concentration of K ethyl xanthate necessary to induce contact between an air bubble and anglesite and cerussite respectively was investigated as a function of the pH. Anglesite responds most readily between pH 9 and 11, cerussite at pH below 9. Na_2CO_3 increases the concentration of ethyl xanthate necessary to induce a response at surfaces of anglesite and cerussite. Controlled concentrations of Na_2S activate anglesite and cerussite so that they respond to lower concentrations of xanthate, but excess of sulphide prevents a response. Cerussite responds more readily to xanthate after an initial treatment with Na_2S. It is argued that the activation is due to the formation of a surface film of PbS. There is a corresponding blackening of the surface. The response of anglesite and cerussite to amyl xanthate is less influenced by Na_2S than their response to ethyl xanthate. Na_3PO_4 may be substituted for Na_2S as an activator for anglesite and cerussite. Sulphide is consumed in preference to xanthate by these two minerals. It is difficult to control the sulphide concentration in flotation-plant circuits because of the volatility of H_2S. 11 references. JLG (1c)

Froth Flotation of Southern Barite Ores. R. G. O'Meara & G. D. Coe. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 678, Feb. 1936, 6 pages. Laboratory experiments indicated that barite ores could be improved by flotation, the $BaSO_4$ in one ore being raised from 77.2 to 98.1%. For ores not containing fluorite Na_2SiO_3, Na oleate and oleic acid were used. For ores with fluorite Na_2SiO_3 and Emulsol X_1 were found satisfactory. JLG (1c)

Notes on the Balimbing Mine, West Coast of Sumatra. D. W. J. Grey. *Bulletin of the Institution of Mining & Metallurgy,* No. 375, Dec. 1935, pages 1-48. The evolution of the present flow sheet is described in detail. An old tabling and cyaniding plant was scrapped in favor of flotation. Use of a blanket strake before the classifier reduced reagent consumption to Pbac 0.93, Na_2S 0.31, Bu xanthate 0.19, Aerofloat 15 0.14, soda ash 0.90 lb./ton. In August, 1934, treating an ore average 2.79 dwt./ton, 32.6% of the Au was recovered on blankets; flotation recovered 93.6% of the Au from an impoverished head (1.88 dwt.) for an overall recovery of 95.7%. AHE (1c)

Concentration of Molybdenum Ores. B. G. Titov. *Redkie Metallui,* Vol. 4, Sept.-Oct. 1935, pages 15-28. In Russian. Partially oxidized sulphide ores containing 0.42-0.48% Mo were concentrated by flotation. About 98% of the sulphide Mo was recovered in a concentrate containing 52.50% Mo. Reflotation of the tailings recovered the oxidized Mo in a concentrate containing 2.25% Mo. Overall extraction was about 80%. HWR (1c)

Milling Developments at the Benguet Consolidated Plant. J. M. Morris. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 675, Feb. 1936, 13 pages. Tells of the introduction of flotation for treatment of Au ores at a mill in the Philippine Islands. JLG (1c)

Flotation of Molybdenum Ore of the Tura Deposit (Ural) S. I. Mitrofanov. *Tzvetnuie Metallui,* No. 4, May 1935, pages 56-58. The molybdenite ores of the district contain 0.06% Mo. Concentrates obtained in laboratory contained 44-47% Mo (75% MoS_2), and 80-90% recovery was realized. For flotation ores are ground to 200 mesh (75%) and ordinary reagents, xanthate and pine tar, are used. BND (1c)

Obtaining Barite Products from Lead and Zinc Flotation Tailings at the Salair Ore Dressing Plant. A. K. Lebedev. *Tzvetnuie Metallui,* No. 4, May 1935, pages 30-53. The Salair polymetallic ores contain 1% Pb, 7% Zn, 2.7% Fe and 45 to 50% $BaSO_4$. At the present the Zn and Pb are separated by selective flotation, and since 1934 the barite is also recovered by flotation from the tailings. A detailed description of the ore dressing scheme for the recovery of Zn, Pb and barite is given. The recovery of barite is 90% of the amount in the concentrate, or 60% of the material in the ore. The purity of the barite is 92%. Suggestions are given for increasing the recovery of barite to 75% of the quantity present in the ore. BND (1c)

The Effect of the Concentration of Hydrogen Ion and Various Chemicals on the Flotation of Chalcopyrite. Gaichi Yamada, Jiro Wakasugi & Kiyoji Naganuma. *Suiyokwai-shi,* Vol. 8, Mar. 30, 1936, pages 943-950. The Ashio chalcopyrite was finely crushed to —65 mesh and the finest powder, —200 mesh, was removed. Experiments were carried out on the flotation of chalcopyrite in solutions of various pH applying a given amount of flotation reagent, i.e., camphor, white oil and potassium ethyl-xanthate, and adding a small amount of chemicals, e.g., $CuSO_4$, KCN, tannin, NaCl. The floatability of chalcopyrite is about 96%, in a solution of pH-value lower than 10.42. It suddenly decreases from 96 to 84.4 in the range of pH-value from 10.42 to 11.76. With 100 g. and 500 g. of KCN per ton of ore in strong alkaline solution, it is found that the floatability of chalcopyrite gradually decreases, but in the case of 893 g. of KCN per ton of ore it suddenly decreases at pH-value 7.8. HN (1c)

The New Lead and Zinc Flotation Sections of the Concentrator of Broken Hill South Limited. T. A. Read. *Proceedings Australasian Institute of Mining & Metallurgy,* No. 98, June 30, 1935, pages 305-348. The new flotation plant at the South Mine, Broken Hill, is described in detail and metallurgical results are given. AHE (1c)

The Separation of Cobalt and Copper Minerals by Selective Flotation. F. C. Bosqui. *South African Mining & Engineering Journal,* Vol. 46, Part II, Jan. 18, 1936, pages 661-662; (abstract) *Chemical Trade Journal & Chemical Engineer,* Vol. 98, Feb. 14, 1936, page 130. About 75% of the Co, occurring as carrollite ($CuCo_2S_4$) at Nkana, is recovered in the flotation of the Cu. In the reverberatory it remains in the Cu-Fe-S matte. Under the intense oxidizing conditions in the converter, the Co reacts as does the Fe and goes into the slag as the double silicate of Co and Fe. After granulation of the slag, Co is recovered in an electric-arc furnace. From a concentrate containing 2.5% Co, a slag is produced analyzing Co 15.0, Fe 33.0, Cu 2.90 and SiO_2 25.0%. This gives an electric-furnace alloy analyzing Co 55.3, Fe 33.5, Cu 10.40 and SiO_2 0.5%. In order to concentrate the Co, the bulk concentrates, assaying Cu 50, Co 2.0 and SiO_2 7.5%, after filtering and washing were repulped and floated in a cyanide circuit to give a Cu concentrate assaying Cu 56, Co 0.8 and SiO_2 4.0% and a Co tailing. After regrinding, the tailing is refloated in a fresh-water circuit to give a Co concentrate analyzing Cu 47, Co 4.35 and SiO_2 6.0%, containing 30% of the Cu and 70% of the Co, and a tailing assaying Cu 15, Co 1.6 and SiO_2 37.80%, which is returned to the mill. MS + AHE (1c)

Mineral Industries Survey of the United States. Idaho, Shoshone County, Coeur d'Alene District. The Silver Belt and the Sunshine Mine of the Coeur d'Alene District. C. E. Julihn & F. W. Horton. *United States Bureau of Mines, Information Circular* No. 6876, Feb. 1936, 16 pages. Includes brief descriptions of the milling methods at Sunshine and Crescent mines. AHE (1c)

Flotation Processes for the Separation of Mineral Concentrates from Metalliferous Ores. D. C. Gilder. *Journal Institution of Engineers Australia,* Vol. 8, Feb. 1936, pages 67-68. Notes applying to the treatment of the Au bearing ores of western Australia. WHB (1c)

Milling Methods and Costs at Eustis Concentrator of the Consolidated Copper and Sulphur Company. H. A. Baxter & Fred W. Stone. *Transactions, Canadian Institute of Mining & Metallurgy,* 1936 (in *Canadian Mining & Metallurgical Bulletin* No. 286, Feb.) pages 86-97. The ore analyzes Cu 3.71, Fe 30.00, S 34.90, SiO_2 7.82, and Al_2O_3 2.45%. Using CaO 2.520 lbs./ton and NaCN 0.349 lb. in the ball mills and floating with amyl xanthate 0.184 and pine oil 0.386 lb. fed to the classifier overflow gave a Cu concentrate averaging 25.623% Cu with 93.77% recovery. The tailings go to the Fe circuit where the pyrite is reactivated with $CuSO_4$ 1.049, Na_2S 0.556 and soda ash 4.291 lbs./ton. Using butyl xanthate 0.422 lb., 70.43% of the Fe is recovered. AHE (1c)

Cyanidation Then Flotation—New Method Adopted at Kalgoorli. Charles E. Blackett. *Chemical Engineering & Mining Review,* Vol. 28, Feb. 8, 1936, pages 133-136. At the Kalgurli Ore Treatment Co. Ltd. plant at Kalgoorli, W. A. a combination method of precyanidation followed by flotation, roasting and cyanidation of concentrates has been selected. A flow sheet is shown and the various steps outlined. WHB (1c)

The Action of Potassium n-Amyl Xanthate on Chalcocite. A. M. Gaudin & Reinhardt Schuhmann. *Journal of Physical Chemistry,* Vol. 40, Feb. 1936, pages 257-296. In the short time treatment of Cu_2S with xanthate, the xanthate abstracted by the mineral may be accounted for as cuprous xanthate and as an entity unleachable with ordinary solvents. The formation of these products occurs practically simultaneously, although with larger quantities of xanthate the reaction to form cuprous xanthate slows up with increase in quantity of cuprous xanthate on the mineral. In the long time treatment of Cu_2S with xanthate, leachable products other than cuprous xanthate are formed relatively slowly. All the K of the K xanthate remains in the solution. Hydroxide, carbonate, sulphate, and reducing ions $(S_mO_n)^{--}$ are thrown into the solution in a total amount mathematically equivalent to the xanthate abstracted from the solution. Leaching off the leachable products from xanthate-treated chalcocite has no appreciable effect on the flotative properties of the Cu_2S. Pyridine extracts cuprous xanthate from xanthate-treated and leached Cu_2S, i.e. from Cu_2S having the "unleachable" film. The "unleachable" product increases with increase in xanthate added, approaching a maximum in a manner suggestive of adsorption. The maximum amount of unleachable xanthate attainable with a given sample of Cu_2S corresponds to a complete mono-molecular film on the Cu_2S. If the quantity of xanthate just sufficient for effective flotation is added, it may be almost completely accounted for as the unleachable product. Only a relatively small fraction of the monomolecular film of "unleachable" is necessary for efficient flotation. The fraction of the surface filmed determines the dryness of the mineralized froth. Increasing the surface of the mineral by longer grinding increases the unleachable portion and decreases the cuprous xanthate portion of the reaction products. The unleachable water-repellent film may be produced by the adsorption of cuprous xanthate from benzene solution by the Cu_2S. There is an essential difference between the collecting actions of xanthate on Cu_2S and malachite respectively. An unleachable water-repellent film is not formed on $CuCo_3.Cu(OH)_2$ by xanthate. EF (1c)

■ 1e. Amalgamation, Cyanidation & Leaching ■

A Study of the Occurrence and Amenability to Leaching of the Phosphorus Compounds in Some Red Iron Ores of Alabama. Ellis S. Hertzog. *United States Bureau of Mines, Report of Investigations* No. 3294, Dec. 1935, 9 pages. Most of the P in these ores occurs as $Ca_3(PO_4)_2$ mixed with small quantities of ferrous, ferric and Al phosphates. Thoroughly leached outcrop ores usually are low in P compared with unleached ores. Acid solutions are the best solvents for $Ca_3(PO_4)_2$. The acid consumption increases with increased $CaCO_3$ content. The P in ores in which the $CaCO_3$ content is small is not removed by weak acid solutions. $FePO_4$ is removed by strong acid solutions, which also dissolves appreciable amounts of the Fe ore. A cheap reagent is essential. It must not introduce any objectionable element into the ore. The removal of P from the red Fe ores of Ala. by leaching does not appear to be commercially feasible. AHE (1e)

Physical Characteristics of Gold Lost in Tailings. R. E. Head. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 674, Feb. 1936, 9 pages. Au in tailings was studied microscopically and by microchemical methods. Most of the Au particles are covered with a film, while the particles in the concentrate are bright. The film may be magnetic and usually contains Fe. All particles are rough and the film may be a tarnish or a slime coating. The response of pyritic ores to cyanidation depends on the porosity of the pyrite rather than on the brightness of the Au. Several possible methods for recovering Au are suggested. JLG (1e)

Effect of Lime on Cyanidation. W. G. Clarke. *Chemical Engineering & Mining Review,* Vol. 28, Jan. 8, 1936, pages 99-100. An investigation of tailings from the Beryl mine, Kemdip, W.A., which contained oxidized Cu minerals, but are free from Pb compounds is reviewed briefly. Some of the tailings were roasted for 3 hrs. in a wood fire muffle furnace at a gradually increasing temperature to 650° C. Loss during roasting was 5.3% and the assay value of the calcine was 6.6 dwt. Au/ton. Cyanidation tests were conducted on unground calcine and calcine after grinding wet in pebble mills to 81% — 200-mesh. A pronounced and progressive decrease in Au extraction results with increased lime alkalinity in the pregnant solutions. The amount of Cu in the pregnant solutions is low compared with tests on the cyanidation of raw tailings and the consumption of cyanide is not excessive. When the pregnant solution contains no free alkali the cyanide consumption is much higher and the balance is exceedingly sensitive. Cu and Pb apparently play no vital part in preventing solution of the Au. WHB (1e)

Electrocapillary Amalgamation. Osborn Cutler Shepard. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 676, Feb. 1936, 10 pages. As the negative potential of Hg increases the surface tension first increases and then decreases.' Experiments proved that as this potential was increased the ability to amalgamate Au particles decreased and then increased greatly. This is due to changes in surface tension of Hg. Na in the amalgam acts to produce negative potential and therefore aids amalgamation. Tests with ores washed over amalgamated plates with and without the plates being at a potential showed that for certain potentials the proportion of the Au in the ore recovered was increased. With too high a potential the amalgam tended to hold pyrite and become ineffective. Well water high in salts could not be used successfully with electrocapillary amalgamation because a white deposit was formed on the amalgam. JLG (1e)

Leaching Alunite with Sulphuric Acid. L. C. Pan. *Chemical Industry,* China, Vol. 10, Jan. 1935, pages 35-42. In Chinese. The best strength of H_2SO_4 for leaching alunite calcined at 500° C. was found to be about 15% by weight. Little advantage was gained by heating the leaching solution even to 100° C. The yield of alum by crystallization, however, was found to be greatest when acidity was minimum. Size of alum crystals formed was found to be minimum from solution containing 4.7% H_2SO_4. The sizes were about the same from 0.133 N H_2SO_4 as from 3 N H_2SO_4, but larger as the acidity was further increased. LCP (1e)

Increased Output in the Mining Industries by Better Utilization of Existing Sources (Leistungssteigerung im Bergbau durch bessere Ausnützung der zur Verfügung stehenden Hilfsquellen) Fr. Saueressig. *Montanistische Rundschau,* Vol. 28, Apr. 1, 1936, 3 pages. Discusses the possibilities of increasing metallurgical recoveries by extracting metal values from old slag dumps and from accumulations of low grade ores and tailings, by more efficient handling of waste gases and by treatment of flue dusts, purification residues, electrolytic slimes, and similar metallurgical byproducts. Proper methods of briquetting, sintering and agglomeration facilitate the treatment of such materials. Addition of suitable fluxes during these operations makes the subsequent smelting processes more efficient. BHS (2a)

Some Engineering Aspects of the First Report of the Blast Furnace Practice Sub-Committee. Thomas B. Mackenzie. *Journal West of Scotland Iron & Steel Institute,* Vol. 43, Part 2, Nov. 1935, pages 19-40. Pertinent engineering data are given for each of 18 basic practice furnaces, 13 hematite practice furnaces, and 14 foundry practice furnaces. One furnace is operated by each practice. When making foundry Fe its output is 95%, and when making hematitic Fe is 93.3% of the output when making basic Fe. The coke consumption for foundry Fe is 110.1% and for hematite Fe is 115.5% of that for basic Fe. The coke consumption/ft.^{2} of hearth is $25 - 0.06D^2$ for basic practice, $25 - 0.067D^2$ for hematite practice, and $28 - 0.052D^2$ for foundry practice in which D is the hearth diam. in ft. Description of the equipment of the basic furnaces includes hot blast stoves; means of cooling the bosh wall, of charging the furnace, of providing the blast; and the volume of blast. Formulas that represent British practice relate the important furnace dimensions to the hearth diam. and to the tons/hr. production. FGN (2b)

Progress at the Blast Furnace in '35. A. J. Boynton. *Blast Furnace & Steel Plant,* Vol. 24, Jan. 1936, pages 55-56. No outstanding innovations in construction or operation took place. Changes have been chiefly further adoption and increased use of methods and apparatus already known. Among changes proposed to furnace itself is so-called Venturi top. Improved bell construction consists of a horizontal sectional cast-steel spider carried by the bell rod and surmounted by a frustum of a cone made of plates and angles. Increasing attention continues to be paid to preparation of raw materials and to application of instruments. Much interest is being shown in use of blast-furnace gas for metallurgical purposes. MS (2b)

Some Blast Furnace Problems for '36. Wm. A. Haven. *Blast Furnace & Steel Plant,* Vol. 24, Jan. 1936, pages 43-46. Means must be found for duplicating at full blast the results obtained with slow blowing in keeping down coke consumption and flue-dust losses. High blast temperatures, which aid in better coke practice, may be obtained by installation of new stove linings. With clean gas there is need for a refractory for the top courses of stove checkers, which is inert to alkaline dust at the prevailing temperatures. To reduce flue-dust losses, tops have been enlarged, but results have not been up to expectations, due to poor distribution of stock under the large bell. Remedy for this condition will require rather radical departures from present designs or equipment. Among proposed improvements are elimination of large bell and filling stock up into hopper; and division of large bell into 2 concentric parts, operable as a unit as a bell of large diam., or singly, using inner section as a bell of small diam. and other section as a deflector or auxiliary stock-line. MS (2b)

Relative Desulfurizing Power of Blast-Furnace Slags. W. F. Holbrook & T. L. Joseph. *Metals Technology,* Feb. 1936, *American Institute Mining & Metallurgical Engineers Technical Publication* No. 690, 19 pages. A laboratory method was devised for determining the relative desulphurizing powers of slags of varying composition. Data and diagrams are presented for 1500° C. and for blast-furnace slags containing up to 10% Mg. No simple relationship was found by which composition as designated by the term "basicity" could be compared with S removal. To relate basicity and desulphurization MgO cannot be combined with CaO as total bases, nor can Al_2O_3 be combined with SiO_2 as total acids. Moreover, Al_2O_3 cannot be ignored in computing basicity. Each oxide has its own effect on desulphurization, and the degree of the effect is not constant for all ranges of composition. MgO was slightly deleterious to desulphurization of acid slags. The effect becomes increasingly undesirable as basicity is increased to that of slags of average composition. The presence of MgO is decidedly favorable to desulphurization in the more basic slags. Evolution of CO accompanying desulphurization probably has an important role in the over-all process. It retards the descent of falling metal drops and carries CaS and globules of metal away from the bath interface and into the slag, in both instances contributing to the effectiveness of the reaction. 8 references. Beneficiation of Low-Grade Ores Will Prolong Life of Mesabi Range. E. W. Davis. *Iron Age,* Vol. 136, Nov. 14, 1935, pages 30-31, 41. **Ore, Furnace Technique Must Develop Together.** *Steel,* Vol. 97, Sept. 30, 1935, page 48. Abstract of paper read before the Chicago convention of the western division of American Mining Congress. Discusses the application of Fe ore beneficiation to blast furnace practice. Future reserves of the Mesabi Range are low-grade ores, and they must be utilized for the manufacture of steel at a cost which will compare favorably with cost of producing steel from high-grade ores. Before low-grade ores may be used not only mining and beneficiation operations but smelting and refining operations should be improved. Gives present cost of agglomerating fine Fe concentrate and the effect of increase in future taxation on the cost. MS + VSP (2b)

3. MELTING, REFINING AND CASTING

Practical Metallurgy. I. Melting and Casting (Praktische Metallkunde. I. Schmelzen und Giessen) Georg Sachs. Julius Springer Verlag, Berlin, 1935. Cloth, 6¾ x 10 inches, 272 pages. Price 22.50 RM.

Most of the assembled metal products on the market contain castings of one sort or another. Sand, permanent mold, die castings, etc. are most frequently used. They must be free from blow holes, and by having good physical properties, give as few rejects as possible. Although the art of making castings is very old, the theoretical knowledge of the flow of metals, gating, etc. is very limited. Practical experience in many cases has to fill the gap.

This book tries in a systematic way to explain many practical questions which confront engineers and casting superintendents, referring for the greater part to non-ferrous metals.

The writer has had many years of theoretical and practical experience in the field of non-ferrous metals and due to this, the data and information compiled in this volume are very valuable. The chapter on gases in metals and the influence of slight impurities on the physical and chemical properties of metals and alloys is of special interest. Many chapters are too general and too short to be of great value, as for example the chapter on die castings.

In general it may be stated that the attempt to handle so many different problems in 300 pages was successful. Fred J. Tobias (3) -B-

Process Charts Reduce Costs. Albert J. Saute. *Foundry,* Vol. 64, Feb. 1936, pages 31, 78. Discusses the advantages of process charts in the foundry and the method of making them. Gives several examples. VSP (3)

Mould and Core Materials at Elevated Temperatures. *Foundry Trade Journal,* Vol. 53, Dec. 26, 1935, pages 469, 470 and 466. Discussion on Hudson's paper, *Foundry Trade Journal,* Dec. 5, 1935, pages 411-416. See *Metals & Alloys,* Vol. 7, Apr. 1936, page MA 176L/2. AIK (3)

Molding Sand Testing Apparatus. H. W. Dietert. *Sands, Clays & Minerals,* Vol. 2, Apr. 1936, pages 161-166. Methods and apparatus for testing strength, moisture, fineness, permeability, flowing properties, sintering point and deformation are described. Ha (3)

Assemble Flask Sections in Combination. R. M. Cheney. *Foundry,* Vol. 64, Feb. 1936, page 84. Due to constant change in machine tools and other miscellaneous castings many changes are involved in length, width, depth and bar arrangement in flasks. Logical solution is to adopt definite standard sizes for flask sections which may be assembled in any desired combination. Describes method used by author. VSP (3)

G. L. CRAIG, SECTION EDITOR

Melts Scrap Metal in Brass Foundry. *Foundry,* Vol. 64, Mar. 1936, pages 26-27, 68. Where all scrap is used an intimate knowledge of miscellaneous material is required in making up charges. In ordinary jobbing brass foundry a great variety of castings may be made from all or nearly all scrap charges provided the foundryman is familiar with the material with which he is dealing. As a typical example describes procedure at the Keystone Brass Works, Erie, Pa. Includes a table giving the composition of typical brass and bronze mixtures. VSP (3a)

Comparison of Press Casting and Other Shaping Methods for Brass and Various Copper Alloys (Vergleich des Pressgusses und anderer Formgebungsverfahren für Messing und andere Kupferlegierungen) *Die Metallbörse,* Vol. 25, June 22, 1935, pages 786-787; June 29, 1935, pages 818-819. The author critically discusses why, in spite of its great perfection, press casting of brass and other Cu alloys will never completely displace forging, stamping, die, sand casting and other shaping methods. The most widely used press casting machines are described and the effect of various alloying elements on the press casting properties of Cu-rich alloys are considered. Brass containing 4-5% Si and 10-15% Zn is particularly suited for press casting purposes. A comparison between the brass press casting and Zn-base alloy die casting processes is made from the economic viewpoint. EF (3a)

Molds Numerous Types of Bronze Castings. *Foundry,* Vol. 63, Dec. 1935, pages 30-31, 66, 68. Describes casting procedure at the plant of Erie Bronze Co. Shop is equipped to handle castings from one oz. up to 2 tons. A 10 ton stock of solid and cored P bronze bushings is maintained. With slight variations most of bronzes are melted at temperatures of 2300° F. While in furnace metal is covered with a special flux. Additions of Ni, Mn and P are made in form of shot. Gives details of several mixtures and melting practice. Most of the castings are made in molding machines. VSP (3a)

Production of Powdered Alloys of Low Melting Point. R. W. Rees. *Journal Institute of Metals,* Vol. 57, No. 2, 1935, pages 193-195. See *Metals & Alloys,* Vol. 6, Nov. 1935, page MA 436R/8. (3a)

C. H. HERTY, SECTION EDITOR

Hydrogen as a Cause of Low Ductility in Steel (Wasserstoff als Ursache geringer Dehnung und Einschnürung von Stahl) C. Drescher & R. Schäfer. *Archiv für das Eisenhüttenwesen,* Vol. 9, Jan. 1936, pages 327-332. Basic open-hearth steel (C 0.16%; Si 0.9%; Mn 1.0%; P 0.042%; S 0.04%; Cu 0.38%) deoxidized with Al showed low elongation and reduction of area and a spotty tension test fracture. After heating at the low temperature of 500° C. or even 100° C. the ductility was raised and a uniform cup and cone fracture obtained. In experimental steels melted with inflow of H_2 flaky fractures of low ductility were obtained in the as cast, as forged, or normalized condition, but the flakiness and accompanying low ductility disappeared on heating at 100° C. In discussion there was rather general agreement that the low ductility was probably attributable to absorbed H_2. SE (3b)

Sand and Loam Molds (Die Schablonenformerei in Sand und Lehm) A. Geissel. Wilhelm Knapp Verlag, Halle (Saale), 1935. Paper, 6½ x 9½ inches, 137 pages. Price 7.50 RM.

This book, illustrated with 222 pictures (cuts) and 3 tables, is a guide for the practical foundry manager who would be interested in ferrous jobbing work of difficult nature requiring special mold preparations with brick work, sweeping arm, loom work and dry mold practice.

The addition of barn yard refuse and hair is recommended in core sand.

Design and Application of Electric Steel Melting Furnaces, in Particular in Plants for High-Quality Steel (Ueber Bau und Anwendung der Elektrostahl-Schmelzöfen, insbesondere in Qualitätsstahlwerken). F. Pölzguter. *Elektrowärme,* Vol. 6, Jan. 1936, pages 38-46. Advantages of melting alloy steels electrically are discussed, furnace types described, and operating data given. Ha (3b) 1

2 **Recent Progress in Steel Making Reported from Germany. A correlated abstract.** S. Epstein. *Metals & Alloys,* Vol. 6, May 1935, pages 113-117; June 1935, pages 160-164; July 1935, pages 181-184; Aug. 1935, pages 219-222; Sept. 1935, pages 247-251. 53 references. Data are assembled on various aspects of steel making chemistry. Equilibria between slag and bath with effects of various oxides; temperature and production of fluid products of deoxidation; effects of C in bath on gas evolution; solubility of inclusions in liquid steel are discussed. Work on the effect of gases in steel (H, CO, N) is discussed. Slag requirements for desulphurization in basic open-hearth furnace are given. Two defects, "sand seams" and "flakes" have been extensively studied and this work is summarized. Statistical methods have been used in study of sand seams. The cause of flakes is more elusive depending upon melting, casting, forging, and heating and cooling rates. H absorption is said to be largely responsible for susceptibility to flake formation. Data are assembled resulting from work on slag control, use of Mn ore in open-hearth operation, jarring of ingots during solidification and direct rolling of molten steel. WLC (3b)

3 **Core Room Layout Features English Automobile Foundry.** Vincent Delport. *Foundry,* Vol. 63, Dec. 1935, pages 26-28, 71-72. Describes core room of the Austin Motor Co., Birmingham, England. The foundry is highly mechanized plant dealing with repitition work. Two types of sand are used. Sand is blown into core boxes. After cores are baked they are classified and placed on racks. Sand is constantly tested. VSP (3b)

The Use of Cement Sand in Steel Molding (Ein Beitrag zur Verwendung von Zementsand in der Stahlformerei) A. Gottwald. *Giesserei,* Vol. 22, Dec. 6, 1935, pages 603-604. A mixture of 100 parts (by weight) of sea sand, 13 parts of Portland cement and 10 parts of water is a very good cement sand for molding alloy and unalloyed steel castings, both acid and basic, for pieces 4 up to 1 ton, in particular for hard Mn steel. It is useful also for gray Fe for piston rings and cylinders. Ha (3b)

Steel Making in Relation to Weld Rod Manufacture. T. Swinden. *Symposium on the Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 2, pages 593-601. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 4R/6. (3b)

6 **Evolution of Modern Methods for Purification of Steel (Evolution des procédés modernes d'épuration de l'acier)** Perrin. *Revue de Métallurgie,* Vol. 32, Oct. 1935, pages 466-468. Using deoxidation method proposed by the author (not described in the present paper) and open hearth metal made in any way and specified only by its C content and temperature, it is possible to control depth of quenching, to adjust the metal to give optimum properties after any desired heat treating cycle, to control the grain even in plain carbon steels and to adjust any desired factor one at a time. JDG (3b)

7 **Impurities and Purification of Steel (Impuretés et Purification de l'Acier)** Albert Portevin. *Bulletin de la Société des Ingénieurs Soudeurs,* Vol. 6, Aug.-Oct. 1935, pages 1914-1930. Lecture before the Société des Ingénieurs Soudeurs. Elements which are considered as impurities can be useful in some cases. Alloy elements can be harmful in some circumstances. For example: S is harmful for forgeability but is kept high to improve machinability. P is kept or added to prevent sticking during rolling. Cu which was considered as an impurity is now added to increase corrosion resistance. N is used in nitriding process. As also has been patented to improve machinability of stainless steels. C is an impurity in 18/8 Cr-Ni steels. Mn must be kept low in dynamo sheets and tool steel and for preventing atmospheric corrosion. Si must be low in sheets for deep drawing, etc. Amount of each element must also be taken in consideration. Little is scientifically known about Ca, O, Al, N, H owing to 8 difficulty of accurate determination of those elements. Furthermore effect of an impurity depends upon condition of this impurity in steel. Cr, S, Al and N for instance can be present as solid solution or in the combined state. Distribution of impurities is also of great importance. A special discussion is devoted to inclusions, interdendritic segregation and purification of steel. Chief purpose of purification is to eliminate S, P and O. 2 processes are used: (1) Precipitation. In the case of steel this method consists in adding C, Al, Ca, Na, Mg. Solid or liquid particles can be separated only partially and are present as inclusions in final product. (2) Extraction. In the case of steel, the slag absorbs the impurities. Author discusses static and kinetic chemical conditions of purification by slags and gives special attention to the new Perrin process. FR (3b)

9 **High Grade Cast Iron.** *Machinery,* London, Vol. 47, Nov. 21, 1935, pages 209-215. The production and working of Meehanite castings at the Rochester Works of Winget, Ltd. General discussion of foundry for producing cast Fe used in concrete-mixing and tile manufacturing machinery. WB (3b)

Gaseous and Solid Impurities in Ingots. J. H. Andrew. *Aluminium & the Non-Ferrous Review,* Vol. 1, Nov. 1935, page 59. Read before the Midland Metallurgical Society. A short general review. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 54L/8. JCC (3b) 10

Modern Foundry Production Methods. J. J. Sheehan. *Journal Institution of Production Engineers,* Vol. 14, Nov. 1935, pages 582-586. Further discussion of paper. For abstract of original paper see *Metals & Alloys,* Vol. 6, Apr. 1935, page MA 141L/9. JCC (3b)

Facts About Common Steels. J. R. Miller. *Blast Furnace & Steel Plant,* Vol. 24, Feb. 1936, page 171; Mar. 1936, page 243. Brief discussion of blast furnace, acid Bessemer and acid and basic open-hearth processes. MS (3b)

Modern Equipment for Chevrolet Foundry Increased Production 550%. *Mill & Factory,* Vol. 18, Mar. 1936, pages 42-48. Grey Iron Foundry at Saginaw, Mich., has in 16 years increased its output per employee from 200 lbs. to 670 lbs., and per square foot of floor space, 550%, with 50% cost reduction, by the introduction of modern machinery, conveyors, etc., by constant redesign of castings, and by adoption of short cuts wherever possible. Quality has improved, giving a more machinable cylinder block, and fewer leaky sections. Detailed description is included of plant equipment and layout, furnace charges, pattern-making, molding, pouring, conveying, etc. Maintenance costs and extent of personnel required are outlined. FPP (3b)

Cast Iron. *Marine News,* Vol. 22, Feb. 1936, pages 26, 33-36. Extract from second Andrew Laing lecture, N. E. Coast Institute of Engineers & Shipbuilders, Nov. 3, 1933, on recent metallurgical developments and their significance for shipbuilding and marine engineering. Various data from the paper and bibliography are put into tabular form and discussion is made of the effects of various alloying elements. WB (3b)

Present State of Die Casting (La fonderie sous pression: état actuel) Paul Bastien. *Revue de Métallurgie,* Vol. 33, Jan. 1936, pages 43-54. Recent Work on the Treatment of Cast Iron and Steels with Sodium Carbonate (Les Travaux Récents sur le Traitement des Fontes et des Aciers par le Carbonate de Soude) R. Berteaux. *Chimie et Industrie,* Vol. 33, May 1935, pages 631-638. Reviews the recent studies on the effect of sodium carbonate, which produces modifications in the structure, and reiterates the vital importance of desulphurization of the bath because of the effect on the quality of the product. MAB (3b)

Electro-Metallurgical Production of Iron-Silicon Alloys (Les Fabrications Electro-Métallurgiques des Ferro-Siliciums) Maurice Déribéré. *Science et Industrie, Electricité,* Vol. 20, Jan. 1936, pages 22-24. Gives a history of the subject and explains fundamentals of production. Furnaces with a single electrode and a current conducting hearth are the most used but other types of arc furnaces and resistance furnaces are sometimes resorted to. Problem is only to reach a high temperature. Author describes recent developments in arc furnace construction. Tension used varies from 25 to 80 volts per electrode. Capacity of furnaces is up to 25,000 kw. Current consumption varies according to Si content of alloys and capacity of furnaces. Typical numbers are as follows: for 25% Si, consumption is, in kw. hr./ton 3,200-4,000 for a furnace of capacity up to 4,000 kw. 3,000-3,500 for a furnace having a capacity over 4,000 kw. For 90% Si, corresponding consumptions are respectively 13,000-20,000 and 11,000-16,000. World production of Fe-Si alloys is about 200,000 tons. FR (3b)

The Production of Medium Sized Steel Castings. G. T. Hampton. *Iron & Coal Trades Review,* Vol. 132, Feb. 14, 1936, page 315. There are 2 fundamental differences between the production of Fe castings and steel castings; steel has a much lower proportion of metalloids and therefore a higher m.p. and decreased fluidity range, and in cooling there is greater contraction from the liquid state and volume changes are undergone when passing through the critical range. A closer coöperation between designer, pattern maker, molder and metallurgist together with departmental supervision is therefore necessary for successful operation of a steel foundry. Shrinkage and dimensions, application of chills and correct estimation of factors involved are discussed. Ha (3b)

Finishing the Heat of Steel. Pts. XL and XLI. J. H. Hruska. *Blast Furnace & Steel Plant,* Vol. 24, Feb. 1936, pages 160-161; Mar. 1936, pages 239-240, 257. Discusses supporting lugs or hooks for ingot-molds; molds accelerating solidification of steel; and design of mold stools. Any type of lifting lug should be constructed with sufficiently rounded corners. Wrought-Fe hooks are to be preferred to those of soft iron or Bessemer or open-hearth steel because of better impact resistance. Air or H_2O cooling of molds has not yet found commercial acceptance. Cu molds are used in only a very few plants. Mold stools should be designed with thorough consideration for mechanical and thermal requirements, but otherwise with greatest simplicity. Heavy stools are less likely to crack prematurely. Part XLI. Discusses grading of ingot-steels and making of forging ingots. Ranked according to origin, electric and crucible steels are first, open-hearth grades next, and Bessemer steel last. Whether acid or basic grades are to be preferred has not been settled definitely. In addition to low P and S, other factors, such as presence of O_2, should be considered in judging quality of steels. Forging ingots are generally produced from well finished killed steel. Quality forgings require proper deoxidation of melt, use of polygonal or round cross-sections of ingots and molds, and very careful pouring practices. Cold pouring is advisable in most cases. MS (3b)

Cast Iron and the Electric Furnace (La fonte et le four électrique) Auguste Le Thomas. *Revue de Métallurgie,* Vol. 33, Jan. 1936, pages 14-23. Electric furnace can be used either for making pig iron for remelting or for melting iron in the foundries. Greatly improved properties can be given by this method as compared with a blast furnace iron melted in a cupola. JDG (3b)

Foundry Pig Iron Made in Smaller Size. G. A. T. Long & W. M. Ramsey. *Steel,* Vol. 98, Mar. 16, 1936, pages 55-56. "Meltrite" pig-Fe introduced by Picklands-Mather & Co., while of the same length, is of much smaller cross-sectional area than customary pigs. New-type pigs weigh about 40 lbs. each. Their use in cupola or air furnace results in more uniform and faster melting, and lower oxidation losses and fuel consumption. If heavy pig-Fe or heavy scrap is used in addition to new type of pig, heavy sections should be charged first. MS (3b)

Desulphurization of Pig Iron and the General Laws Governing the Desulphurization of Iron. Hanns Wentrup. *Iron & Steel Institute, Carnegie Scholarship Memoirs,* Vol. 24, 1935, pages 103-166; *Technische Mitteilungen Krupp,* Vol. 4, Mar. 1936, pages 38-58. The laws governing the desulphurization of Fe are discussed and many data including that of the author and many previous investigators are presented to show that desulphurization can now be described to a greater extent in quantitative terms than previously. Desulphurization depends on temperature and also on (1) the solution of S in the slag, (2) a reduction in the power of Fe to dissolve S, (3) the conversion of Fe sulphide into sulphides which are insoluble in Fe, (4) a combination of (1) and (3), and (5) a combination of (2) and (3). The ratios of S in the slag to S in the Fe under various conditions are calculated by use of the partition law. The author shows that a reduction in the power of Fe to dissolve S is brought about by such elements as C, Si, and P which force S out of the Fe. Mn causes desulphurization by converting Fe sulphide into an insoluble Mn sulphide. In slag desulphurization the reaction is usually between Fe sulphide and the oxide of Mn. Parts of important systems presented and discussed in this investigation include the following: Fe-S, Fe-S-O, Fe-S-C, Fe-S-P, Fe-S-Mn, Fe-S-Mn-O, Fe-S-Ca-O, Fe-S-Mn-C, Fe-S-Mn-C-Si, Fe-S-Mn-C-P, and Fe-S-Mn-C-P (-Si). Numerous equilibrium constants are calculated and interpreted to show the course of the desulphurization of pig Fe. The authors conclude that to insure a satisfactory desulphurization, C, Si, P, and Mn should be present in the Fe and the Fe should be cooled. C, Si, and P reduce the saturation content of S at temperatures of 1250-1350° C. strongly enough to start the desulphurization required in practice. Desulphurization of pig Fe in the ladle and mixer is simply a process of the segregation of the Fe and Mn sulphides. 46 references. Ha + CW (3b)

Study on Formation of Iron Nitrides Through Melting and on Iron-Nitrogen System (Etude de la Formation des Nitrures de Fer par Fusion et du Système Fer-Azote) D. Seferian. *La Technique Moderne,* Vol. 28, Jan. 1, 1936, pages 10-12. In steel, N imparts hardness but also brittleness according to content. Author summarizes study of Fry and explains briefly nitriding process. Direct action of N on molten steels has been but little studied. Very little N is dissolved but steel becomes brittle. Quantity of N absorbed depends upon melting process: For open hearth steel, N content is about 0.010%, for converter steel N content can reach 0.020%. During torch melting (welding) N absorption can also reach 0.020% and when welding is carelessly performed can give a N content up to 0.20%. Author deals more particularly with latter point. FR (3b)

Some Experiences with the Balanced Blast Cupola. H. H. Shepherd. *Proceedings Institute of British Foundrymen,* Vol. 26, 1932-1933, pages 348-372. See *Metals & Alloys,* Vol. 5, Oct. 1933, page MA 332. CEJ (3b)

Contribution to the Supply of Blast in the Cupola Furnace (Beitrag zur Windversorgung des Kupolofens) Hans Schmidt. *Giesserei,* Vol. 23, Feb. 28, 1936, pages 107-111. An investigation on a cupola has shown that the usual methods of determining the blast are not quite correct. A certain excess of air must be considered which burns the CO in the upper part of the shaft and thus escapes the gas analysis. Ha (3b)

Coke Consumption 6% and Charge 100% Scrap! (Koksverbrauch 6% und Schmelzeinsatz 100% Bruch!) Carl Rein. *Giesserei,* Vol. 23, Feb. 14, 1936, pages 78-81. The fallacy of low coke consumption by wrong reference of coke to charge is explained; no exclusive scrap charge can be used continually, first because of poor quality of the Fe produced and second, for economic reasons, as soon not enough scrap would be available. Ha (3b)

Bibliography of Literature on the Effect of Aluminum in Cast Iron. Bureau Report No. 145. G. R. Woodward with notes by J. W. Bampflyde. *Bulletin British Cast Iron Research Association,* Vol. 4, Jan. 1936, pages 264-271. 51 chronologically listed references given which do not include textbooks or patents. WB (3b)

Relation Between the Design of the Burners, Output, and Refining of Basic Open-Hearth Furnaces (Zusammenhänge zwischen der Kopfbauart, Leistung und Frischwirkung von Siemens-Martin-Oefen) F. Wesemann. *Stahl und Eisen,* Vol. 55, Sept. 12, 1935, pages 981-989; Sept. 19, 1935, pages 1006-1009. A large amount of data are given to show that the design of the burners affects not only the furnace output but also the manner of refining through the rate of C drop and degree of oxidation of the bath. Reducing the excess air lowered the output. SE (3b)

New Vacuum Furnace and Its Use for Oxygen Determination in Steel (Ein neuer Vakuumofen und seine Anwendung zur Sauerstoffbestimmung im Stahl) G. Thanheiser & E. Brauns. *Archiv für das Eisenhüttenwesen,* Vol. 9, Mar. 1936, pages 435-439; *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Vol. 17, No. 18, 1935, pages 207-211. A new vacuum fusion apparatus for the determination of O_2 in steel is described. The blank being very small the furnace may prove suitable for also analyzing other gases in steel. The interfering effect of Mn on O_2 content was studied and found to depend on the cooling conditions above the crucible. Ha + SE (3b)

Develops Aluminum Flask for Producing Test Bar Molds. Edward Grant. *Foundry,* Vol. 64, Jan. 1936, pages 33-34. Describes flasks developed to facilitate production of cast Fe tensile and transverse test bars. Flasks are made up of 2 cast Al plate sides, 6 steel cross members and 2 steel end plates. Side plates are ⅜" x 4" x 18" and 6 steel strips are 3/6" x 1" held by screws in recesses in edges of plates. VSP (3b)

Changed Design of Corebox to Speed Production of Tank Cores. G. O. Ekstedt. *Foundry,* Vol. 64, Jan. 1936, page 34. Casting loss due to wet paste joints, improperly gaged cores or weak stop-off are eliminated by new design of corebox for tank heaters. The equipment designed by author produces a one piece core, thus eliminating the rubbing of old type of half cores to a bearing, and gaging complete core for size. Green core is made in 2 half boxes, but they are joined to form a complete core before core is placed in oven. VSP (3b)

4. WORKING

Some Non-Ferrous Metal Powders. J. C. Chaston. *Aluminium & Non-Ferrous Review,* Vol. 1, Mar. 1936, pages 229-231. The manufacture, characteristics, and uses of Mg, Al, Cu, and Pb powders are briefly reviewed, with special reference to the importance of correct particle shape. Mg powder for pyrotechnics is made by machining thin shavings from the solid, Al powder by the stamp mill or, more recently, the Hametag ball mill processes, Cu powder by electrolysis, and Pb powder for paints by atomizing molten metal. Extrusion of Nickel and Its Alloys. W. R. Barclay. *Metal Industry,* London, Vol. 47, Nov. 15, 1935, pages 494-496. Author reviews possibilities of extrusion of Ni alloys. One advantage of this process is that alloys difficult to forge may, when extruded, be cold-worked with greater ease. Until recently extrusion of Ni and its alloys has received little consideration, due to the fact that they are in the "high temperature" range. The properties of Ni which make extrusion difficult, mechanical strength at high temperatures and resistance to deformation, together with toughness and resistance to heat and corrosion are the properties that make extruded alloys valuable to industry. Examples are cited of Ni-containing alloys that are being extruded in tubes and in sections. Close collaboration between engineer and metallurgist is essential. The development of the presses necessary for this work is discussed and problems of both the engineer and the metallurgist are cited. In addition to the factors mentioned, the fundamental requirement for successful extrusion is the casting and preparation of the billets to be extruded; unless the metal is clean, free from slag, blowholes, and surface defects, and uniformly heated throughout, satisfactory extruded material cannot be obtained. HBG (4b)

Pressing of Nickel and Its Alloys (Das Pressen von Nickel und seinen Legierungen) W. R. Barclay. *Metallwirtschaft,* Vol. 15, Mar. 13, 1936, pages 253-255. The many fine properties of Ni alloys will force the development of a pressing technique comparable to that now existing for Cu and Al alloys. Better mechanical equipment can be produced and attention must also be directed to proper working speeds and temperatures and the use of high quality alloys. GD (4b)

Forging and Heat Treating Locomotive Parts. J. B. Nealey. *Iron Age,* Vol. 137, Mar. 19, 1936, pages 38-42. Discusses in detail the forging and heat treating operations as well as the equipment used in the Pennsylvania Railroad shops at Altoona, Pa. Several economies were effected when furnaces were changed from producer gas or oil to manufactured gas. VSP (4b)

Cold Extruding of Aluminum Shells (Kaltspritzen von Aluminium-Hülsen) O. Kühner. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, Feb. 1, 1936, page 132. The manufacture of Al tubes and shells by extruding is described. The smallest wall thickness obtainable was 0.1 mm., the greatest more than 1 mm. at 8-80 mm. diam. Ha (4b)

■ 4c. Cold Working, including Shearing, Punching, Drawing & Stamping ■

Developments in Steel Wire Manufacture. KENNETH B. LEWIS. *Blast Furnace & Steel Plant,* Vol. 24, Jan. 1936, pages 51-54. Synthetic carbide dies have found general acceptance. They have contributed largely to progress in developing special finishes through their accurate shape, high polish, and ability to do their work with an extremely thin film. Conditions in the pickling and cleaning house have been greatly improved by use of inhibitors—probably greatest single factor—use of automatic temperature control, ventilation, and periodic testing of acid and lime baths. Recently introduced baking-ovens are in the form of long narrow compartments, constructed of insulated steel panel sections, through which preheated air is circulated at automatically controlled speeds and temperatures. Importance of inherent grain size is receiving increased attention. There is a growing interest in stress distribution in wire during its passage through the die. It is possible that large reductions in friction loss and power requirements can be effected by giving wire a preliminary stressing by a backward pull on free end, thus reducing pressure between die and wire. MS (4c)

Some Recent Developments in Tungsten Die Practice. JAMES R. LONGWELL. *Wire & Wire Products,* Vol. 11, Feb. 1936, pages 72-75, 100. The advantages of W carbide, its recent improvements and the economies to be obtained by the use and proper care of carbide dies in the production of sheet metal parts, in the bolt and nut industry, and in using cemented carbide for upsetting punches and header dies are discussed. Ha (4c)

Manufacture of Steel Tubes. Mechanical Operations and Their Effects. J. W. JENKIN. *Iron & Coal Trades Review,* Vol. 132, Jan. 10, 1936, page 45. The steel used in England for the manufacture of steel tubes is usually a mild steel of the killed type composed of 0.10-0.15% C, 0.3-0.8% Mn, up to 0.3% Si, and S and P each below 0.04%, generally below 0.03%. Inclusions which are ductile are not injurious to the tubes, as e.g. Mn sulphide, but non-ductile inclusions, such as alumina and silicates, can give considerable trouble both in hot and cold working as they interfere considerably with the flow of material in mechanical operations. Oxide inclusions, although rarer, are equally harmful. The Mannesmann, Stiefel and Pilger mills are described. The properties of tubes are affected by manufacturing methods of the products for which the tube is used, brazing being very often a process which makes the tube extremely brittle by the non-ferrous metal penetrating the steel along the grain boundaries. Intergranular failure can occur by oxidation at high temperatures, e.g. in superheater tubes; caustic embrittlement of boiler plates also is an intergranular failure. Under alternating stress at high temperatures, with oxidation, failure is hastened just as corrosion accelerates fatigue failure at ordinary temperature, due to trans-crystalline and inter-crystalline high temperature corrosion fatigue. Ha (4c)

Cold Deformation of Metallic Materials and Its Influence on Quality with Particular Consideration of Cold Working of Aluminum (Die Kaltverformung metallischer Werkstoffe und ihr Einfluss auf die Gutwerte unter besonderer Berücksichtigung der Aluminium-Kaltverformung) LEONHARD WEISS. *Aluminium,* Vol. 18, Mar. 1936, pages 96-97. Cold deformation is applied to a metal to improve its surface and also its properties. As Al has a strong tendency to combine with steel, cold working of pure Al is used only to a limited extent. Tensile strength and hardness are increased, electric conductivity is reduced. The increase of strength in a metal by cold processes depends on the conditions of working (reduction), and the latter depend on, and are limited by, the shape and dimensions of the material. The properties are the more improved the less energy the cold deforming process requires, that is, the easier the material follows the deforming forces. Ha (4c)

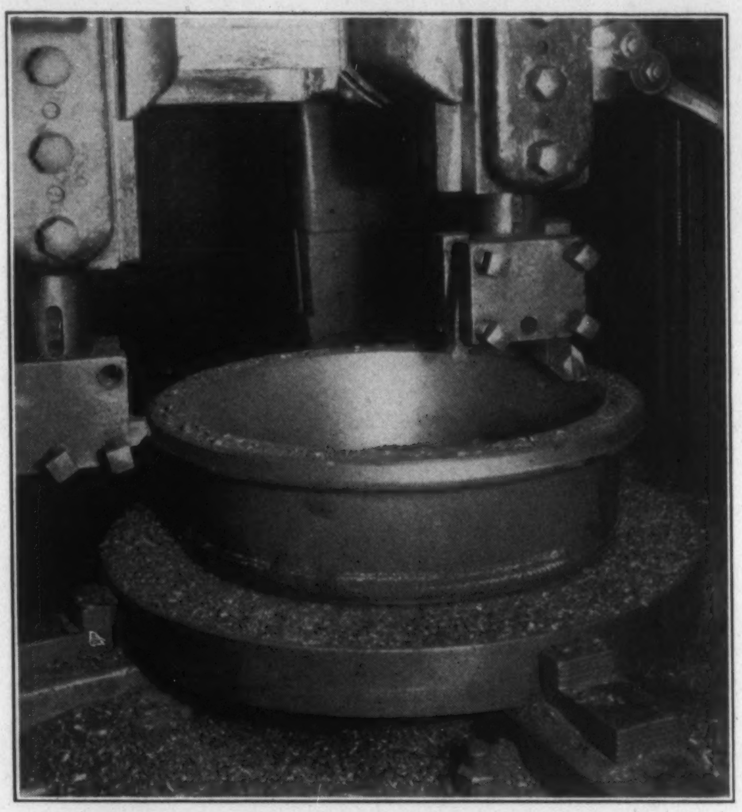
Steadiness of Chip Pressure Makes Economical Reaming. EDWIN L. CADY. *Mill & Factory,* Vol. 18, May 1936, pages 61-63. Reaming theorists are divided into 2 schools advocating (1) abundance of reaming stock, slower speeds, lighter feeds and rigid alignment, or (2) less stock, high speeds, heavy feeds and floating reamers. Successful reaming is discussed with reference to miniminzing bell mouth and chatter, and to improving accuracy, service life and operating economies. In spite of theories the reaming chip pressures are the most important factors; control of chip pressure is easier when its effect on the reamer may be ignored and only its effect on speed and accuracy need be considered. Chip pressures are influenced by material to be worked, kind of hole, and companion operations, as fixed factors. Adaptable factors are speeds, feed, stock, lubricants, etc. FPP (4d)

Recent Developments in Small Tools. FRANK W. CURTIS. *Iron Age,* Vol. 137, Jan. 2, 1936, pages 277-280, 282-284, 286, 288, 290; Jan. 9, 1936, pages 10-16. Recent developments in small tools have contributed greatly to art of metal cutting. Solid high-speed steel tools for milling cutters, drills, reamers and hobs are available in 3 types of steel. Most common is the standard 18% W, 4% Co and 1% V. More recently the addition of V up to 2% performs better on certain types of cuts. Another type of steel is a super high-speed, containing 18.5% W, 4.5% Cr, 1.75% V, 1.00% Mo and 9% Co. This steel is better for heavy duty cutting. Improvements in high-speed steel have been directed more toward refinement of structure and physical properties to insure uniformity. Combination tools are becoming more universal. Turning tools are also receiving gradual improvements. Discusses Firthite tipped tools. Other tools considered are carbide tools, radius cutters, broaching tools and sintered tungsten carbide tools. VSP (4d)

Plymouth Flywheel Machined at Rate of 44 an Hour in Two Operations. *Iron Age,* Vol. 137, Apr. 9, 1936, pages 44-45. Flywheels are machined in 2 operations by a battery of 2 radial slide simplimatic lathes. Results are attributed to a new design which permits maximum number of cutting tools to cut simultaneously at high speed. Tungsten-carbide and stellite J-metal tools are used in roughing operations. Bed and headstock are cast from Ni semi-steel. VSP (4d)

A Tough Job Made Easy
with
FIRTHITE



"Firthite Tools machining cast iron brake drums.
Brinell Hardness 196 to 207.
Depth of cut 3/16" to 5/16".
Speed 140 feet per minute.
Time between grinds 15.2 hours.
Number of pieces between grinds 40.
Two grades of High Speed Steel were tried on this job before Firthite was used. One grade gave one piece per grind at 80 feet per minute, and the other grade failed completely at that speed."

Out-of-date cutting materials jeopardize economies and the increased output expected from modern machine tools while Firthite assures both.

Firthite Sintered Carbide Tools are the most up-to-date tools obtainable and permit higher speeds, with greater accuracy and finer finish on machining operations such as: turning, milling, boring, or drilling, on non-ferrous metals, cast irons or hard steels, bakelite, rubber, asbestos, and other abrasive products.

A tool or two will convince you of the worth while possibilities of this cutting material.

5. HEAT TREATMENT

O. E. HARDER, SECTION EDITOR

5a. Annealing

Practical Annealing of Steel Castings. J. R. MILLER. *Heat Treating & Forging,* Vol. 22, Apr. 1936, pages 188-190. Annealing of steel castings improves strength, due to grain refinement, decreases resistance to wear, and tends to make a large casting or group of castings more uniform in quality. Amount of improvement that can be attained depends upon condition of casting when it comes out of the sand, particularly with reference to grain size and composition, segregation, etc. Heat treatment of coupons should be carried out while coupon accompanies casting itself and not in the laboratory. As low-C castings require higher temperatures than high-C castings, furnace load should consist of castings of similar composition. Heating up must be done very slowly. No part of casting should be at too high a temperature and soaking time should not be prolonged beyond that which is necessary. Charge must be carefully cooled in furnace to a cherry red and then may be air cooled. Presents results of tests on a large number of acid open-hearth steel castings with varying C content, about 0.04% P, 0.60-0.80% Mn, and 0.30-0.35% Si. These indicate that annealing improves ductility in all C ranges, increases ultimate strength where C is more than 0.30%, and increases yield-point where C is more than 0.35%. However, the last property is decreased in the case of the lower C ranges. Machinability of all castings is improved.
MS (5a)

Notched-Bar Bend Tests of Longitudinal and Transverse Specimens—Influence of Annealing and Overstrain. J. MUIR. *Journal Royal Technical College,* Vol. 3, Jan. 1936, pages 531-541. The results of notched-bar bend tests on specimens similarly cut from the same bar, 1½" diameter, of 0.30% C steel, when the steel was in the normalized condition as supplied, when it was overstrained by tension, and after annealing at 920 and 1000° C., are given. It was found that longitudinal specimens snapped at the V-notches, the fibers being broken across, while with the transverse specimens the fibers were simply torn asunder, the specimen opening out at the V-notches without snapping. The fibrous nature of the material, whether normalized or annealed, is shown by photographs of the fractured sections of the notched-bar which have been cut transversely from the original bar.

5c. Aging

Age-Hardening of Brass. KANZI TAMARU. *Kinzoku no Kenkyu,* Vol. 13, Apr. 1936, pages 150-155. In Japanese. "Inkubationszeit" in aging 4 : 6 brass was re-examined by hardness test, electric resistance measurement and differential thermal analysis. Specimens, 59.11% Cu, having diameters of 4.2 mm. and 1 mm. respectively, were quenched from 870° C. and aged at different temperatures in high vacuum. The results of investigation are as follows: (1) The "Inkubationszeit" was not found in both electric and hardness measurements. (2) The electric resistance in quenched state is larger than in the annealed state. This fact is in contrary to Hansen's conclusion. (3) The electric resistance in quenched state was nearly the same as the sum of 3 electric resistances, that is, that of annealed state, that due to the quenching stress and that due to the transformation. (4) In aging, a faint heat absorption was found near 130° and 460°; a small heat evolution at 260° and a larger one at 310°, respectively. The first heat absorption seems due to the atomic rearrangement and the one at higher temperature to the transformation from β' to β. The small heat evolution is due to the separation of α phase from β and the larger one to the transformation from β to β'.

The Mechanism of Age-Hardening—A Review of Recent Researches. *Metal Industry,* London, Vol. 47, Nov. 1, 1935, pages 435-439; Nov. 8, 1935, pages 464-468. Primarily this article deals with the basic mechanism of age-hardening. Certain examples of age-hardening alloys such as Al-containing Monel metal, Cu, alloyed with 2.5% Be and their physical properties are discussed. In its broader application, age-hardening is now defined as embracing changes, not always beneficial, as a result of exposure in or passage through a suitable range of temperatures. In present article the term is used, in a more restricted sense, to changes in hardness and auxiliary phenomena accompanying these changes, of alloys showing these effects without subjection to cold work. The author endeavors; (1) to summary of observations contained in recent papers which tend to indicate the mechanism of age-hardening; (2) to consideration of the constitution of age-hardening alloys, based on data from various types of testing; and (3) to a discussion of some theories and speculations that have been advanced. 121 references.

Steam Driven Air Supply with exhaust used for heating

If you can use exhaust steam to advantage, it may be possible to secure your air supply at little or no cost.

The two Spencer Turbo-Compressors, illustrated below, are an example. The motor-driven turbo-compressor, at the left, is used only for starting, and the steam turbine driven turbo-compressor, at the right, is used for continuous service. The exhaust from the steam turbine is used for heating.

This is a threefold economy. The Spencer Turbo, a centrifugal-type machine with wide clearances and only two bearings, is the most economical and reliable method for obtaining air service. The steam turbine, located near the boiler, is a highly efficient method of obtaining power, and even the exhaust steam is in this case a valuable by-product of the operation.

While the vast majority of the thousands of Spencer Turbos used in the metal industry are standard units, The Spencer Turbine Company is always interested in special applications. The Spencer "Midget," a 1/3 Hp. unit, is one example of a special machine that usage in large quantities has now made standard. Gas-tight and corrosion-resistant Spencer Turbos are another example of the adaptation of a. standard product to special conditions.

Let our engineers figure on your special problems. Bulletins on request.

5e. Carburizing

Decarburization of Several Alloy Steels by Hydrogen (Entkohlung einiger legierter Stähle durch Wasserstoff) W. Baukloh & H. Guthmann. *Archiv für das Eisenhüttenwesen,* Vol. 9, Oct. 1935, pages 201-202; (abstract) *Foundry Trade Journal,* Vol. 53, Dec. 19, 1935, page 457. The decarburization in H_2 at 700° to 1000° C. of several C steels and Ni, Cr, Mn, Si, W, Mo, V, Sn, and Cu steels, was determined. In C steels above 700° C. the rate of decarburization increased with increasing C content; below 700° C. it decreased. Steels containing 0.9% Cr showed the most resistance to the effect of H_2.

AIK + SE (5e)

5f. Nitriding

Present State of Nitriding Technique for Steel and Cast Iron (L'état actuel de la téchnique de la nitruration de l'acier et de la fonte) Federico Giolitti. *Revue de Métallurgie,* Vol. 33, Mar. 1936, pages 145-156. Critical summary of published data. For 90% of all used, 2 types of steel are sufficient: 0.20-0.55% C, 0.15-0.35 Si, 0.40-0.55 Mn, 1.40-1.80 Cr, 0.15-0.30 Mo, 1.0-1.20 Al and 0.25-0.55 C, 0.20-0.35 Si, 0.40-0.60 Mn, 1.70-2.00 Cr, 0.20-0.35 Mo, 0.30-0.40 Al. For each group, C content might be subdivided into 0.20, 0.40 and 0.50 range. Ni should be kept under 0.20%. Wide permissible variations both in composition and heat treating permit obtaining with these steels 45-160 kg./mm.^{2} tensile strength, 35-145 kg./mm.^{2} elastic limit, 28-6% elongation, 28-5% reduction of area. Steels of the first group have 1200 Vickers hardness, those of the second 900 to 1000. Hardness and wear resistance of nitrided steels of the second group is better than that of carburized and heat treated steels leading to rapid replacement of the latter. This is further promoted by the lack of deformation and strains in nitrided articles. An intermediate alloy between the 2 previous groups containing 0.6 Al and about the same content of other elements. Its properties lie between the two. When impact resistance is required Al is cut down to 0.10-0.15, but Cr raised to about 2.6%, Mo to 0.45 and about 0.20 V is added. One group of alloys is composed so that the core hardens on heating during nitriding. Austenitic steels are used only for valves of internal combustion motors, and only the valve stems are nitrided. Nitriding practice is described. Some industrial applications are given. Only centrifugally cast Fe can be nitrided easily, because the other methods of forming it still result in much trouble during nitriding. Nitrided cast Fe pipes are used commercially to advantage. Composition is not standardized as yet, but a representative one is: 2.7% C, 2.5 Si, 0.7 Mn, 2.0 Cr, 0.3 Mo and 0.8 Al.

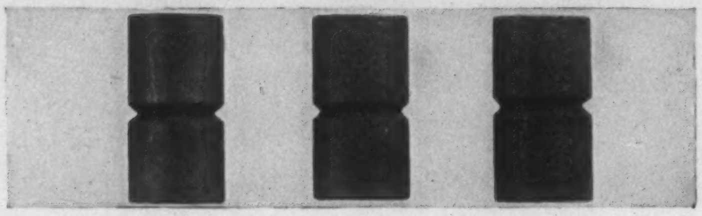
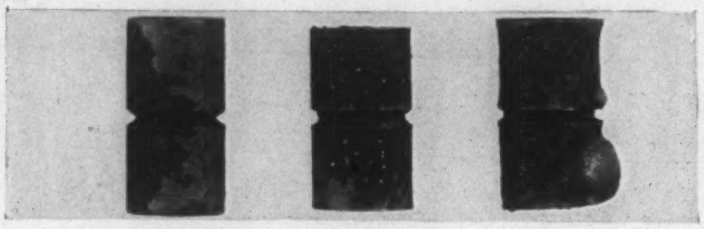
Fuel Fired Furnaces
SALEM, OHIO
Electric Furnaces

With which furnace could you produce the best tools?



A
CERTAIN CURTAIN
Pre-Combustion Control

Above are three of six identical pieces of high speed steel, one held normal, one twice normal and one three times normal in "Certain Curtain" Pre-combustion Control furnace atmosphere. Note there is no attack on the surface.



B
OTHER FURNACE
Burning Gas Control

Here are three more of the pieces, one held normal, one twice normal, and one three times normal in another furnace whose "atmosphere control" readings were exactly the same as in the "Certain Curtain" Furnace above. Note destruction of the surface on the two held over time.

YOU want your hardener to do a lot more than merely avoid spoilage—you expect him to bring out the MAXIMUM WORKING QUALITIES of the steels he heat treats. He can do this with a "Certain Curtain" furnace because he can give the tools plenty of time at the critical without fear of surface attack.

The Hayes patent is the only one which provides PRE-COMBUSTION of the furnace atmosphere gases, thus assuring a stable, uniform, consistent furnace atmosphere which produces the difference in results noted above. Other furnaces may give you the same manometer readings and

Other furnaces: Point-of-Perfection — Margin-of-Safety — Tool held proper length of time at desired temperature — TOOL SPOILED

CERTAIN CURTAIN FURNACE: Point-of-Perfection — MARGIN — OF — SAFETY — Tool held proper length of time at desired temperature — Tool may be held many minutes past Point of Maximum Hardness without injuring the steel

even the same analysis of furnace atmosphere samples, but they do not give you the same effect on the steel—which is all you care about.

A team of "Certain Curtain" furnaces should rapidly pay for itself in your plant. Investigate the LEADER!

6. FURNACES, REFRACTORIES AND FUELS

M. H. MAWHINNEY, SECTION EDITOR

Considerations in Developing a Mineral Wool Industry. CHARLES F. FRYLING & ORVAL WHITE. *Chemical & Metallurgical Engineering,* Vol. 42, Oct. 1935, pages 550-553. From a paper given before the Third Annual Mineral Industries Conference of Illinois, Urbana, May 18, 1935. Manufacture and future developments in manufacture of mineral wool are discussed. The important use is heat insulating material. Present day cupola practice is described. Corrosion of refractories caused trouble in initial brick furnace. PRK (6)

Foreign Raw Materials in German Electric Furnaces (Fremde Rohstoffe im deutschen Elektroofenbau) W. FISCHER. *Elektrowärme,* Vol. 6, Jan. 1936, pages 13-17. Metals and refractories which have to be imported into Germany for the construction of electric furnaces are discussed. About 50 tons of Ni are used yearly; Cr and asbestos are some of the imported materials. Replacement by domestic materials is investigated. Ha (6)

Steel Ladle Refractories. A. JACKSON. *Metallurgia,* Vol. 13, Jan. 1936, pages 93-94. Discusses materials and design of refractories, including lining, sleeves and stopper head. JLG (6)

Recent Developments in Refractories. C. E. MOORE. *Iron & Coal Trades Review,* Vol. 132, Jan. 3, 1936, page 4. Improvement of existing and creation of new refractory materials in recent years are discussed. Accuracy of size and shape have been considerably improved without increase of cost. The alumina content in firebricks is now higher than formerly, and sillimanites are used extensively. Smaller sizes have been found advantageous and more economical. Carborundum and siloxicon are widely used in muffles, furnace tubes, refractory supports. Clay-bonded carborundum is now generally reserved for uses such as kiln tiles, furnace bottoms and crucibles where neither the greatest refractoriness nor the highest thermal conductivity are required. Severe conditions are met with by crystallized carborundum which possesses both high thermal conductivity and great strength. Zr silicates have found application where the high price permits, as in laboratory and special furnace work; although this material is non-spalling and has high refractoriness and strength, its slag resistance, especially to metallic oxides, is poor. Ha (6)

Use of Pulverized Fuel in Copper Refining. A. G. MILLS. *Chemical Engineering & Mining Review,* Vol. 28, Jan. 8, 1936, pages 94-98. A description of the development of the equipment used and the operations required in the production of Cu wire bars and refined shapes at the Electrolytic Refining Co. of Australia, Ltd., Port Kembla, N.S.W., particularly the application of pulverized coal firing. WHB (6)

The Manufacture and Use of Insulating Firebrick in the United States. F. H. NORTON. *Engineering,* Vol. 141, Feb. 7, 1936, page 162. From a paper read before the Refractory Materials Section of the Ceramic Society, London, Nov. 1935. LFM (6)

Bituminous Coal for Higher Temperatures in Open-hearth Furnaces. THEODORE NAGEL. *American Institute Mining & Metallurgical Engineers, Contribution* No. 100, Feb. 1936, 5 pages (mimeographed). Modern practice demands higher temperatures than can be produced by the usual producer gas. These have been produced with natural gas, coke-oven gas and fuel oil. The lower temperatures of combustion of producer gas are due to N_2 dilution at the gas producer. The paper contains new presentation of combustion thermo-chemistry, tabulations of the relative thermal values of gas fuels, and the relative costs and comparative values as applied to open-hearth practice. Production of producer gas with less N_2 dilution, generated from bituminous coal with an O_2-rich blast, is proposed and a method for generating this gas of higher thermal value is presented, including data for producing low-cost O_2 of 95% purity. The data are claimed to warrant the attention of bituminous coal producers and open-hearth steel operators. JLG (6)

Electric Annealing Furnaces and Their Heating Elements (Elektrische Glühöfen und ihre Heizelemente) W. ROHN. *Elektrowärme,* Vol. 6, Jan. 1936, pages 17-20. Electric annealing furnaces are divided into 5 groups, according to their operating temperatures: (1) up to 800° C., with heating elements of alloys with 15-20% Cr, 30-20% Ni, remainder Fe; (2) from 800° to 950° C., with elements of 15-20% Cr, 10-20% Fe, remainder Ni; (3) from 950°-1100° C., with Fe-free Ni-Cr elements of about 20% Cr, 80% Ni; (4) from 1100°-1250° C., elements of 20-30% Cr, 6-4% Al + Si, remainder Fe; (5) from 1250°-1450° C., here ceramic heating elements of silicon carbide must be used. The influence of furnace atmosphere, temperature change and dimensioning of the heating elements on their life, and economical considerations in the investment of higher or lower first cost are discussed. Ha (6)

The Behaviour of Refractory Materials Under Torsion at Different Temperatures—Kaolin and Kaolin-Silica Mixtures. A. L. ROBERTS & J. W. COBB. *Engineering,* Vol. 141, Jan. 31, 1936, page 133. From a paper read before the Refractory Materials Section of the Ceramic Society, London, Nov. 1935. LFM (6)

Refractories for Foundry Use. W. J. REES. *Engineer,* Vol. 160, July 19, 1935, page 72; *Engineering,* Vol. 140, Sept. 13, 1935, pages 289-290; *Mechanical World & Engineering Record,* Vol. 98, Aug. 9, 1935, pages 121-122. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 62R/4. LFM + WH (6)

Factors to be Considered in the Insulation of Open Hearth Furnaces. GILBERT SOLER. *Blast Furnace & Steel Plant,* Vol. 23, Nov. 1935, pages 799-800; *Heat Treating & Forging,* Vol. 21, Dec. 1935, page 592. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 62R/5. MS (6)

means

Accurate Temperature Records

In the improved Foxboro Potentiometer Recorder the electrical measurement is transferred to the chart in the simplest, most direct and positive manner possible. *The recording device is mounted on the same carriage as the slide-wire contacts*—every time the contacts move, the recording device must move exactly the same distance. There can be no errors due to backlash of gear trains or slippage of pulley arrangements—therefore, no need for additional mechanisms to take up the slippage.

This original Foxboro development is but another of the many features that make this Pyrometer outstanding in accuracy and lasting reliability. New Bulletin 190-1 gives full details.

DUCTILE KANTHAL LONGER LIFE

Here illustrated are two sections of Kanthal Wire coiled on mandrils and stretched when cold. It answers the query, "Is Kanthal ductile."

Send for sample and make your own test.

MADE IN
3 GRADES
EASILY
FABRICATED
2462°F
2372°F
2102°F

Kanthal D is indicated where greater resistance and longer life is desired than is available with nickel chromium alloys.

Kanthal A and A-1 have safe operating temperatures 300° to 400° higher than nickel chromium. Kanthal wire is drawn exclusively in the United States in our own Wire Mills at Southport, Conn.

THE C.O. JELLIFF MFG. CORP. SOUTHPORT, CONN.

Hydrogen Furnaces for Tube Parts. *Radio Engineering,* Vol. 16, Mar. 1936, pages 6-7. An illustrated description and discussion of pre-assembly processes for cleaning, brazing, and degassing radio tube parts. The importance of control in the operation of these furnaces is great—the temperature must be controlled within a very limited range, H flow must be sure and at a definite rate and the water passing through the cooling chamber must be held at a temperature which will maintain the cooling chamber above room temperature by the correct amount. WHB (6)

Gas Firing Improves Columbia Tool Steels. *Natural Gas,* Vol. 17, Jan. 1936, pages 8-9. Improvements in quality of finished product and reduction in scale losses have followed installation of completely controlled gas-fired furnaces for forging of tool steels. Time, temperature and atmosphere are automatically regulated, firing speed has been increased 500% and thermal efficiency 50%. Absence of smoke stack considerably lessens original cost of plant. FPP (6)

Acme Uses Modified "Laboratory" Slab Furnaces. *Iron Age,* Vol. 137, Feb. 20, 1936, pages 38-39, 51. Discusses the stabilization of heating operation attending a 16" hot strip mill at the plant of the Acme Steel Co., Riverdale works. Original installation consisted of 2 furnaces, but because of the variation in character of tonnage a third furnace was added. No. 3 furnace was of the laboratory type and results showed that the 3 furnaces gave different results. Therefore certain modifications were made in No. 3 furnace, and No. 1 and 2 furnaces were rebuilt in order to give similar results. Gives advantages of alterations. VSP (6)

Continuous Bright-Annealing and Normalising Furnaces for Steel Strip and Sheets. *Engineering,* Vol. 141, Apr. 3, 1936, page 369. Describes a bright-annealing furnace developed by Birmingham Electric Furnaces, Ltd. It is a continuous furnace for bright annealing and normalizing of hot and cold rolled strips and sheets intended for deep drawing and press work. Material is treated in a single layer, under accurately controlled conditions of temperature and atmosphere, and arrangement is such that the time-temperature cycle for any desired hardness is readily determined. VSP (6)

Normalising Rolled Steel Strips. *Electrical Review,* Vol. 118, Apr. 3, 1936, page 490. Stourbridge Rolling Mill has installed a continuous, electric bright-annealing furnace. It handles short lengths as well as coiled strip. Hourly output is 6 cwt. of material 0.020"-0.25" thick and up to 12" wide. Heating chamber is divided into 3 sections, temperature in each being independently and automatically controlled. Cooling chamber is H_2O jacketed. Reducing atmosphere is provided by burning coal-gas and air in a special generator. MS (6)

Small Cupola Constructed to Meet Delivery Requirements. CYRIL BRECKNOCK. *Foundry,* Vol. 63, Dec. 1935, pages 34-35. To reduce operating costs the Lorain Castings Co. constructed a small cupola lined to 24". It is mounted on a car-wheeled truck and charged from same platform as large cupola. To facilitate cleaning and preparing the cupola, it is made in sections. Approximately 5 tons of Fe can be melted satisfactorily. Unit was built primarily for emergency needs but now it is a vital part of foundry equipment. VSP (6)

P. B. SILLIMANITE RAMMING MIX

again demonstrates its unusual productive and staying qualities . . .

The unusual becomes an every-day performance with P.B. Sillimanite Ramming Mix. But we will let one of the men in your field tell his experience:

"I installed a lining of your P.B. Sillimanite Ramming Mix. This lining ran 633 heats, melting brass, bronze, nickel and some Monel metal, without patching or repairing, and a total of 2630 heats before it became necessary for me to reline the furnace. I would recommend this lining very highly for any furnace requiring high temperature meltings."

That's P.B. Sillimanite in actual service—not promises made by us. Facts from the foundry—and there are others we can tell you. Ask our Engineering Department about your problem.

TAYLOR P B SILLIMANITE

All P. B. Sillimanite made by The Chas. Taylor Sons Company bears this trade-mark—your guarantee of satisfaction

EQUIPMENT . . .
MAKE **GAS** THE
IDEAL
INDUSTRIAL FUEL

CUT COSTS . . .
IMPROVE QUALITY . . .
SPEED UP PRODUCTION
WITH **GAS**

Among the many developments that have helped to establish Gas as the leading industrial fuel have been the many types of controlled atmosphere furnaces. These furnaces are being used throughout the metal working industry, for carburizing, clean hardening and drawing, and clean or bright annealing of ferrous and non-ferrous metals. Results from this equipment have proved to be more practical and economical than by former methods, and quality of work is more uniform and meets a higher standard.

These results were possible because Gas fuel lends itself ideally to Controlled Atmosphere Furnace operations. Manufacturers using this type of equipment report—"Saves in production costs" . . . "Improves metallurgical quality; makes a better product" . . . "Increases production and lowers overall costs" . . . "More accurate control and cleaner operations."

You can depend upon Gas for similar results in *your* heating operations. Call your local Gas Company Industrial Engineer. Without obligation he will give you complete information on this modern better fuel.

Gas-Fired Furnaces for Forging Tool Steels. *Iron Age,* Vol. 137, Jan. 30, 1936, pages 32-33. Describes the first completely controlled gas-fired furnace for forging tool steels at the plant of Columbia Tool Steel Co., Chicago Heights, Ill. The success of the installation is based on a new conception of gas, which involves a recognition of the fact that gas is a valuable metallurgical chemical in addition to being a source of heat. Important advantages lie in the uniformity of product, improved working conditions, no smoke, etc. VSP (6)

The Action of Water Vapour on Silica Bricks at High Temperatures, and Its Possible Industrial Significance. A. G. Dodd. *Engineering,* Vol. 141, Jan. 31, 1936, pages 133-134. From a paper read before the Refractory Materials Section of the Ceramic Society, London, Nov. 1935. LFM (6)

Specific Heat of Gases as an Aid in the Calculation of Equilibria (Die spezifischen Wärmen der Gase als Hilfswerte zur Berechnung von Gleichgewichten) C. Schwarz. *Archiv für das Eisenhüttenwesen,* Vol. 9, Feb. 1936, pages 389-396. A review, particularly of the more recent American work. 24 references. SE (6)

The Blast Furnace Gas Engine in Central Europe. J. D. Watson. *Gas & Oil Power,* Vol. 30, Apr. 1935, pages 81-83. Discusses economics of blast furnace engine construction in German steel plants. Descriptions and diagrams are included of several types of large gas engines available. Because of the low calorific value of blast furnace gas, gas engine manufacturers resort to a system of scavenging and supercharging, claimed to bring the cost into line with that of the equivalent gas-fired boiler and turbine. FPP (6)

Malleable Foundry Duplexes With Cupola and Air Furnaces. *Foundry,* Vol. 64, Jan. 1936, pages 22-24, 63-64. Discusses reduction in production cost made by the Eberhard Mfg. Co., Cleveland, as a result of installing new melting equipment and changing method of distributing and pouring Fe and shaking out castings. The feature of new system is a duplexing unit in which metal is melted in a cupola and treated further in air or reverberatory type furnace fired with powdered coal. Operating at 60% of capacity, the daily heat is 60 tons. In daily operation of air furnace, coal consumption is 250 lb./ton of Fe. VSP (6)

Evaluation of Refractory Materials. The Adsorption Capacity of Refractory Clays and Kaolins (Sui metodi di collaudo dei materiali refrattori. La capacita di sorbzione delle argilli refrattarie e dei caolini) L. Belladen. *La Metallurgia Italiana,* Vol. 28, Feb. 1936, pages 59-64. The sorption capacities, T, of 7 refractories have been determined and compared with various physical properties. Plasticity, measured according to Rieke, increases with T. There is no relation between T and resistance to compression. The modulus of rupture by bending increases linearly with T. In general, shrinkage in drying increases with T, but some exceptions are noted. AWC (6)

Experiences with Special Cements (Erfahrungen mit Spezialzementen) Richard Grün. *Angewandte Chemie,* Vol. 49, Jan. 25, 1936, pages 85-95. The characteristic properties of cements, especially those used in metallurgical processes are described and their best application discussed. Ha (6)

7. JOINING

Flaring Experiments (Einwalzversuche) Block. *Die Wärme,* Vol. 59, Jan. 18, 1936, pages 33-39. Paper before the Zentralverband der Preussischen Dampfkessel Überwachungsvereine, Essen, May 1935, summarizes the speaker's and investigations by Berndt, Lang, Oppenheimer, Ries, Siebel, Jäntscha on the rolling-in of boiler tubes. A complete understanding of this joining method is still lacking and Bloch doubts that this will ever be possible. The flaring process, however, has been solved from a practical viewpoint with remarkable success. EF (7)

Tools for Rolling-In of Boiler Tubes (Werkzeuge zum Einwalzen von Rohren) Helmut Werkmeister. *Die Wärme,* Vol. 59, Jan. 11, 1936, pages 19-26. Paper before the Zentralverband der Preussischen Dampfkessel-Überwachungsvereine, Essen, May 1935, points out that welding and flaring represent the most important tube joining methods in boiler construction. Scientific investigations have advanced the rolling-in process to a remarkable degree. The development of the rolling-in equipment is traced and the latest German facilities are fully described and illustrated. EF (7)

Joining of Aluminum Cables (Herstellung der Aluminiumleiter-Verbindungen bei Kabeln) *Elektrizitätswirtschaft,* Vol. 34, Oct. 5, 1935, pages 633-638. Discusses (I) properties of Al, (II) joining methods of Al power lines by (a) clamps, (b) soldering, (c) welding, including gas, electric and "cast welding." The latter method was introduced in 1935 by a large German concern. A provisional mold is formed around the 2 cable ends to be joined and Al heated to 850° C. is cast into the mold. Mold and excess metal are removed. Bending tests proved that each strand is solidly fused into the joining block of Al. Detailed information is given on this novel joining method. WH (7)

Welding Applications Extended. *Steel,* Vol. 98, Jan. 6, 1936, pages 214, 216, 318-320. Review of progress made in welding and riveting during 1935, as seen by various authorities. MS (7)

■ 7a. Soldering & Brazing ■

C. H. CHATFIELD, SECTION EDITOR

The Development of Low-Melting Point Solders. *Engineering,* Vol. 140, Dec. 27, 1935, page 686. Brief summary of the experimental work carried out during the past few years on solders having melting points ranging from 250° to 550° C. One class of these solders contains Sn and from 5 to 20% Ag and the melting point ranges from 300° to 400° C. The Pb-Ag system has also been used, especially the alloys in the region of the eutectic containing 2.5% Ag which solidify at 303° C. and are fluid at 375° C. It is necessary to use a low-melting flux with these alloys such as $ZnCl_2$ but this is not an ideal flux for the purpose. LFM (7a)

Gold Solders (Goldlote) K. Bihlmaier. *Mitteilungen der Forschungsinstituts und Probieramts für Edelmetalle,* Vol. 9, Nov./Dec. 1935, pages 85-90; Jan. 1936, pages 99-106. Qualities of a good solder for Au and Au alloys are discussed. The basis of industrially used Au alloys are the Au-Ag-Cu alloys, to which nowadays Zn and Cd are added to obtain certain color hues or to reduce the sp.gr. of the alloy as much as possible. Curves are given for the range of melting points of Au-Ag alloys of different Au content and complete tables are given for the composition of solders with a fineness of 750, 585, and 333 parts Au. The preparation of the solders is described in full as the correct melting process and addition of the components is of great importance. 14 references. Ha (7a)

Soldering of Aluminum Cables and Ropes with a Soft-solder Paste (Ueber das Löten von Aluminiumseilen und -kabeln mit einer Weichlotpaste) W. Nicolini. *Aluminium,* Vol. 17, Dec. 1935, pages 648-650. The soldering paste (Alutinol) is composed of 40% Sn, 40% Zn and 20% Cd; it is used with a flux. Tests showed good mechanical properties of the joint which can also be easily worked and has a good electrical conductivity. The soldering procedure is described. Ha (7a)

The Penetration of Steel by Soft Solder and other Molten Metals at Temperatures up to 400° C. L. J. G. van Ewijk. *Journal Institute of Metals,* Vol. 56, No. 1, 1935, pages 241-256. Includes discussion. See *Metals & Alloys,* Vol. 6, Sept. 1935, page MA 362R/3. (7a)

The Proportions and Properties of Silver Solders. H. N. Bassett. *Mechanical World & Engineering Record,* Vol. 98, Sept. 6, 1935, pages 217-218, page 222. Two tables list analyses of British, German and American silver solders and the effects of impurities such as Cd, Sn, Ni, Pb and Fe are discussed. Experimental work on the effect of Mn, Si and P is underway. Physical properties (fluidity, malleability, strength, corrosion resistance) are fully considered and the joining of various non-ferrous materials are dealt with at length. WH (7a)

Brazing New Type Tear Gas Shells in Controlled Atmosphere. *Iron Age,* Vol. 137, Feb. 20, 1936, pages 37-51. **Tear Gas Projectile Electric Furnace Brazed.** *Heat Treating & Forging,* Vol. 22, Mar. 1936, pages 131-132. Describes the electric furnace brazing, with controlled atmosphere, of a new type of gas shell developed by Lake Erie Chemical Co. Parts to go into construction of shell are brazed. Cu brazing is done at 2100° F. in 20 kw. box type furnace with automatic temperature control. Furnace has combustion type atmosphere control which reforms mixture of natural gas and air and which supplies a reducing atmosphere. Brazed joints have withstood hydrostatic pressure of 3000 lb./in.^{2} VSP + MS (7a)

Chemicals in Metal Working. *Chemical Trade Journal & Chemical Engineer,* Vol. 97, Oct. 11, 1935, pages 303-304. See "Solder", *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 65L/6. MS (7a)

7b. Welding & Cutting

E. V. DAVID, SECTION EDITOR

Alton Reconditions 150,000 Rail Ends in 4 Months Time: How the Welding Was Done. M. H. DICK. *Railway Engineering & Maintenance*, Vol. 32, Jan. 1936, pages 17-20. An extensive rail and repair program necessitated by inauguration of high speed passenger service involved 239 track miles of 90 lb. rail and 6 miles of 100 lb. rail. Large, well-organized gangs, togther with use of fast welding technique resulting in high output per welder, assured low average cost per joint welded. Technique described is "straight-line" method, in which metal is applied progressively away from the welder in patches one-half as wide as the rail head. Additional advantage claimed for "straight-line" method is the harder rail-end obtained. FPP (7b)

Hard Facing. DON LLEWELLYN. *Mill & Factory*, Vol. 18, Apr. 1936, pages 70, 136-137. Hard facing of machine parts with welded-on overlays is constantly increasing in application and importance. Large maintenance cost reductions arise from longer life, fewer replacements, salvaging of used parts, saving in power consumption, and increases in operating efficiency. Cheaper base metals may be used for wearing parts. According to specific wear, corrosion or temperature conditions, 4 groups of hard facing materials are available, all applied by either electric or oxy-acetylene methods: (1) tungsten carbide, (2) tungsten carbide imbedded in a mild steel matrix, (3) cast alloy and (4) mild steel mixed with powdered alloys, which when deposited become self hardening. Welding technique is described in some detail. FPP (7b)

Repair of Cracked Bronze Bells by Welding (Wiederherstellung gesprungener Bronzeglocken durch Schweissung) P. BRÄUER. *Autogene Metallbearbeitung*, Vol. 29, Mar. 15, 1936, pages 85-88. The average life of a church bell is about 300 years; the continuous impact of the clapper at the same place causes a cold deformation and internal stresses in the metal which lead to fatigue fracture. Inspecting for fine cracks and repair procedure are explained, and repairs on bells up to 3500 kg. weight are described. Careful heating is absolutely necessary and it must proceed very slowly. Tests have shown that welded bells always had a purer and fuller tone than the unwelded bell. Ha (7b)

New Design of Spot Welding Electrodes. G. KOMOVSKI. *Sheet Metal Industries*, Vol. 9, Sept. 1935, pages 585, 588. See *Metals & Alloys*, Vol. 7, Jan. 1936, page MA 18R/10. AWM (7b)

Modern Methods of Welding. R. S. KENNEDY. *Welding Journal*, British, Vol. 32, Nov. 1935, pages 337-338. General discussion of various phases of arc and flame welding. WB (7b)

Built-up Jigs and Fixtures offer Many Advantages. F. J. BURNS. *Modern Machine Shop*, Vol. 8. Dec. 1935, pages 40-44, 68. Examples show the advantages of welding for these tools. Ha (7b)

Hydrocarbon Fuel Gases for Cutting. GEORGE V. SLOTTMAN. Presented at 36th Annual Convention, *International Acetylene Association*, Nov. 12-15, 1935, 11 pages. Available in mimeographed form from the offices of the Association, 30 East 42nd Street, New York, N. Y. Describes series of practical cutting tests using propane and other hydrocarbon fuel gases, in comparison with acetylene. A greater volume of propane than acetylene was required for the same amount of cutting and the total quantity of O_2 used with propane was considerably greater. Optimum ratios of O_2 to fuel gas in preheating flames were found to be: city gas, 0.75 to 1; natural gas, 2.0 to 1; propane 4.5 to 1; acetylene 1.7 to 1. It was concluded that, at present prices for O_2 and fuel gases, acetylene is the most economical for steel cutting. EVD (7b)

Welding in Rolling Stock Construction. *Commonwealth Engineer*, Vol. 23, Jan. 1, 1936, pages 171-175. This articles describes some of the ways in which welding has been applied by the Victorian railways department in welding rolling stock construction. Improved design and great economy of construction has been achieved by the use of electric welding in the fabrication of buffers, draft gear, automatic couplers, wagon frames, locomotive tenders and car bodies. WH (7b)

An All-Welded Factory Building. *Commonwealth Engineer*, Vol. 24, Dec. 2, 1935, pages 139-142. An illustrated account of the design and construction of a steel framed factory building erected recently in Deer Park, Vic., Australia. The framework was specially designed for fabrication by electric welding and the adoption of this method of construction resulted in a particularly light and economical design. As much as possible of the fabrication was done in the workshop, reducing field welding to a minimum. No difficulties were encountered during erection. WH (7b)

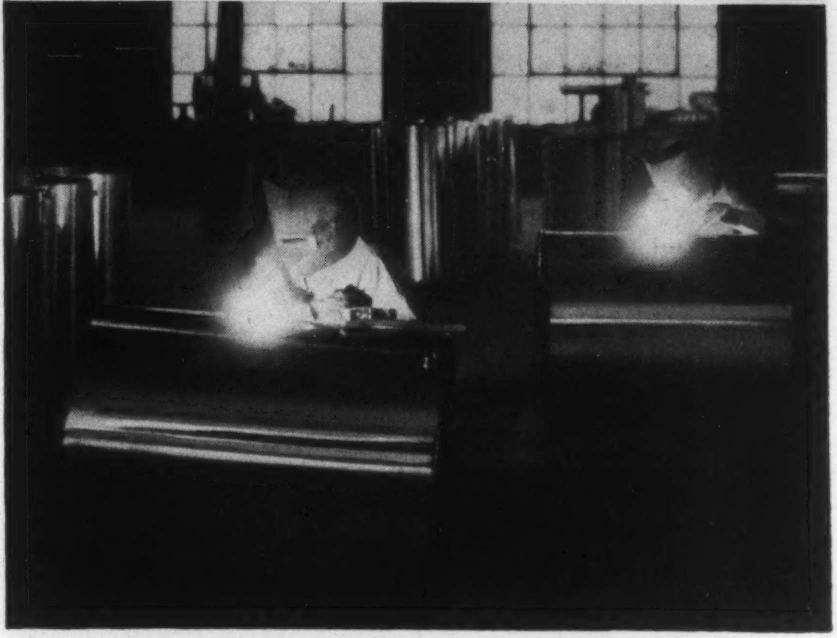
A New Welding and Galvanizing Factory. *Industrial Chemist*, Vol. 11, Aug. 1935, pages 312-314. A brief description of the welding and galvanizing works of Robt. Jenkins & Co., Ltd., Rotherham, England. RAW (7b)

Rebuilding Worn Engine Parts. *Journal of Commerce, Shipbuilding & Engineering Edition*, Nov. 14, 1935, pages 1, 3. A discussion of the application of bronze welding in repair work deals with the composition of various types of welding rods and of the bronze-Si rod in particular, and of the better results obtained from its use. The building up of worn reciprocating parts such as pistons and valves are considered, and the advantages claimed for the bronze-welded rebuilding of pistons is fully discussed from the point of view of cost, methods of procedure, high temperature conditions, and various physical conditions such as severe alternations and repeated stresses. JWD (7b)

Torch Cutting Improves—Design Benefits. *Machine Design*, Vol. 7, Dec. 1935, pages 35-36. Largely refers to statements by E. V. David, James Grant & W. J. Priestley at the Annual Meeting of the International Acetylene Association at Cleveland. WH (7b)

Railway Wagons Sixty-Eight Feet Long with an All-welded Underframe. *Welder*, Vol. 8, Dec. 1935, pages 769-772. The design and welding methods used are described in detail. Ha (7b)

Monel Metal
WELDS
VS
Carbon-Tetrachloride
CORROSION



Carbon-arc welding the Monel Metal tanks for the "Lustrlux" Dry Cleaning System, Butler Mfg. Co., Kansas City, Missouri.

Monel Metal dry-cleaning machines resist attack by the new chlorinated hydrocarbon solvents

IN dry-cleaning machines for use with the new chlorinated hydrocarbon solvents, such parts as tanks, washer shells, condenser-bodies, pressure filters and vapor piping are made of Monel Metal.

Carbon-arc welding is particularly well adapted to the fabrication of the comparatively light gauges (16 and 18 ga.) used in the construction of Monel Metal dry-cleaning equipment in which the seams must be practically as corrosion-resistant as Monel Metal itself.

The following pointers for your operators show the extreme simplicity of carbon-arc welding 16- to 18-gauge Monel Metal sheet:

The polarity should be straight. Use small-diameter carbons (5/32, 3/16 or 1/4"), and to obtain better control of arc, taper them to pencil point for 2".

Keep the heat relatively low, and obtain a uniform, smooth flow with a short arc.

Use coated carbon-arc welding rod (INCO Carbon-Arc Monel Metal #20), and feed rod separately. Don't puddle.

This procedure avoids porosity, cracking... gives uniform penetration.

Information on welding problems relative to Monel Metal, Nickel or Nickel-Clad Steel gladly supplied.

MONEL METAL

INCO
MONEL
METAL

Monel Metal is a registered trade-mark applied to an alloy containing approximately two-thirds Nickel and one-third copper. Monel Metal is mined, smelted, refined, rolled and marketed solely by The International Nickel Company, Inc., 67 Wall Street, New York, N. Y.

"Lad, speaking of high-average batters, here are three I'd like you to work on . . . They are SHOCK, IMPACT and ABRASION."

"A SHUT-OUT, Pop! They'll batter no more with these hard-facers in the box!"

"MANGANWELD"—for reclaiming worn austenitic manganese steel parts containing 11%-14% manganese. Deposit has wear-resisting qualities equal to those of heat-treated cast manganese steel.

"HARDWELD"—High-carbon electrode—for building up worn surfaces—produces dense, tough deposit of moderate hardness, to resist shock and abrasion.

"WEARWELD"—A shielded-arc electrode for refacing parts subjected to rolling or sliding, batter, sand-abrasion and repeated impact. Unusually hard, tough deposit.

"ABRASOWELD"—For building up straight-carbon steel, low-alloy steel or high-manganese steel surfaces where pronounced battering and impact are not encountered. Deposit is self-hardening—highly resistant to corrosion.

"TOOLWELD"—Coated electrode for building super-speed cutting edges on cold rolled stock. Users report deposit lasts even longer than high-cost tool steel. Also used for refacing worn cutting edges on cutting tools, dies, etc., of high-speed steel.

The coupon will bring you a handy guide covering the subject of hard-facing procedure in detail.

Welding in Relation to the Manufacture of All-steel Automobile Bodies. J. C. ARROWSMITH. *Symposium on Welding of Iron & Steel,* May 2 & 3, 1935, *Iron & Steel Institute,* Vol. 1, pages 465-472. Describes different methods of welding automobile bodies as used in England. See also *Metals & Alloys,* Vol. 6, Dec. 1935, page MA 496R/6. JLG (7b)

Industry Adopts Many New Uses for Oxyacetylene. E. V. DAVID. *Steel,* Vol. 97, Nov. 4, 1935, pages 71-73. Progress report of the Oxyacetylene Committee of the International Acetylene Association. Oxyacetylene flame is finding increased use in automobile manufacture, welding of piping, bronze welding of ferrous metals, welding of stainless steels, hard-facing, Ag soldering, metal spraying, machine gas cutting of steel parts, and scrapping. Oxyacetylene process is largely responsible for lighter-weight machines and products. Lists codes and rules issued recently and technical pamphlets prepared by the Committee. MS (7b)

Bicycle Manufacturers Use Resistance Welding to Improve Their Product. *Steel,* Vol. 97, Sept. 23, 1935, pages 58, 62. From *Flashes,* published by Thomson-Gibb Electric Welding Co., Lynn, Mass. Presents details of design for fabrication of bicycles by flash welding. Process is being used to a large extent to cut down weight without loss of strength, improve appearance, and reduce costs. MS (7b)

Skates Made by Resistance Welding. *Steel,* Vol. 97, Sept. 16, 1935, page 31. From *Flashes,* published by Thomson-Gibb Electric Welding Co., Lynn, Mass. Some ice skates are made by roller seam welding high-C steel blade into position in tube member of alloy or stainless steel. Recent type has tubular member folded back and seam welded along edges to form blade. Projection welding is now used to join wheel trucks of roller skates to the body. MS (7b)

Steel Bars and Channels are Cut with Oxyacetylene Flame on New Machine. *Steel,* Vol. 97, Sept. 9, 1935, page 47. Describes fabrication of steel foundry flasks by Sterling Wheelbarrow Co., Milwaukee, Wis. MS (7b)

Steel Tube Manufacture. *Commonwealth Engineer,* Vol. 23, Sept. 2, 1935, pages 41-47. The article describes in some detail the equipment and processing at the Stewarts & Lloyds Pty., Ltd., of Newcastle, N.S.W., dealing not only with the actual work involved but also with such matters as control of furnace and heat recuperation. The heating and welding of the tube, cutting into lengths, finishing, screwing and manufacture of couplings are all carried out by automatic machinery without any handling by hand. WH (7b)

Studies the Weldability of Copper Alloys. *Machine Design,* Vol. 7, Oct. 1935, page 39. Resistance welding current requirements are in direct proportion to the conductivity of the metals to be welded. Replacing Zn by Mn, Si, Sn and Ni improves weldability of brass. Al only up to 3% acts similarly. An 85/15 and 90/10 Cu-Sn alloy is also suited for resistance welding. WH (7b)

The Welding of Chromium Steels in Chemical Plant Equipment. J. R. DAWSON. *Canadian Chemistry & Metallurgy,* Vol. 19, Dec. 1935, pages 337-338. Seven groups of Cr steels are as follows:

Group	% Cr	% C	% Ni
1	12 — 17	over .20	
2	11 — 14	less than .12	
3	15 — 18	less than .12	
4	20 — 30	less than .30	
5	17 — 25	less than .20	7 — 12
6	7 — 25	less than .20	17 — 22
7	Castings — considerable variation of composition.		

The rods chosen in oxy-acetylene welding should be as nearly as possible of the same composition as the materials being welded. A smaller flame should be used on stainless steels than on ordinary steels to avoid overheating of the weld. X-ray examination and the free bend method of testing for ductility have been of great value in checking up on welded products. The selection of the correct steel and procedure for welding for each type of service are important. WHB (7b)

Endurance of Welded Assemblies (Considérations sur l'Endurance des Assemblages Soudés) H. Dustin. *Revue Universelle des Mines,* Vol. 11, Dec. 1935, pages 521-531. Results of tests of fatigue strength made in recent years with most modern machines on welded structures are analyzed. Behavior of modern structural steels, different kind of welded joints, and the stress distribution in the joints are determined and results shown in curves. In general it was found that the fatigue strength as compared with the stresses determined by the load test of bridges had a safety factor of about 2. Furthermore, the endurance limit should never be determined by theoretical or analytical means:—a thorough knowledge of the practical endurance limits of the different types of welded joints is of greater importance. Ha (7b)

1

Welded Piping and Pressure Vessels in the Marine Field. J. W. Wilson. Presented at 36th Annual Convention, *International Acetylene Association,* Nov. 12-15, 1935, 4 pages. Available in mimeographed form from the offices of the Association, 30 East 42nd Street, New York, N. Y. Welded boilers and pressure vessels have been approved by the Bureau of Navigation and Steamboat Inspection. Several installations are in successful operation at pressures up to 450 lb./in.^{2} gage and total temperatures up to 750° F. However the Welding Code of the Bureau now permits welded piping for 100 lb./in.^{2} only. Careful thought and study is now being given to the development of a Code for welding high pressure piping in position on shipboard. Marine piping is subjected to harder usage than stationary plant piping. In addition to usual stresses, it must withstand indeterminate stresses due to rolling and pitching of vessel in a seaway, causing severe twisting, buckling, bending and pulling. Nevertheless welded piping on *S.S. Dixie* remained intact when vessel recently grounded on Florida reef in hurricane which pounded the vessel and placed terrific strains on piping. Not a weld cracked and there were no signs of leakage or distress. EVD (7b)

"Not Only Cut the Cost... But Save Production Time"

"Since adopting Mallory #3 Spot Welding Tips, we have not only cut down the cost of the tips, but have saved considerable production time, because we eliminate the necessity of a lot of filing to maintain clean, well-shaped tips."

So writes one user of Mallory #3 Welding Tips. Before adopting Mallory Points, this manufacturer averaged about 100 assemblies per set of tips. Since adopting Mallory #3, the average has jumped to as high as 1,000 assemblies per set.

This is typical Mallory performance — and one reason why Mallory Leadership is so consistently maintained.

8. FINISHING

H. S. RAWDON, SECTION EDITOR

■ 8a. Pickling ■

Diffusion of Hydrogen Through Steel During Electrolytic Pickling (Wasserstoffdurchlässigkeit von Stahl beim elektrolytischen Beizen) W. BAUKLOH & G. ZIMMERMANN. *Archiv für das Eisenhüttenwesen,* Vol. 9, Mar. 1936, pages 459-465. The H_2 passing through a low C steel sheet 0.64 $dm.^2$ in area on electrolytic pickling was determined. Hydride formers like As, Sb, P, Bi; and Se, Te, S; greatly increased the diffusivity and the presence of these elements in the pickle bath no doubt influences pickling embrittlement and blisters. Hg, Zn and Cd, also increase the diffusivity of H_2 in Fe. However, the hydride formers did not influence the diffusivity of H_2 through Ni, Cu, Zn, Al and Mg sheets. SE (8a)

Corrosion After Pickling Major Source of Galvanizer's Dross. WALLACE G. IMHOFF. *Iron Age,* Vol. 136, Dec. 5, 1935, pages 30-33, 116, 118; Vol. 137, Feb. 20, 1936, pages 30-33, 51. Discusses the reducing action of molten Zn at galvanizing bath temperatures on $FeSO_4$, $FeCl_2$, water rust and Fe_2O_3 formed on surface while drying. A second installment discusses the same action, under some experimental conditions, on $FeO.Fe_2O_3$. VSP (8a)

■ 8b. Cleaning including Sand Blasting ■

The Electrolytic Cleaning of Exhaust Valves. S. D. HERON, GEORGE CALINGAERT & F. J. DYKSTRA. *S. A. E. Journal,* Vol. 37, Dec. 1935, pages 19-21. Removal of engine carbon, scale and Pb compounds, etc. from valves without removal of underlying metal is accomplished by electrolysis in molten mixture of 60:40, $NaOH:Na_2CO_3$, the valve being the cathode with a storage cell discharging 6 amps. through the system. Entire removal of Pb may require anodic treatment in same bath for a short time subsequently to cathodic treatment. Precautions are to degrease, remove oil, and have dry surface before placing valve in molten mixture. Several representative photos are shown. WB (8b)

Improvements in Sand-Blasting Equipment. *Aluminium & the Non-Ferrous Review,* Vol. 1, Oct. 1935, pages 44-46. Rotary-table automatic sand-blast installations are briefly described. JCC (8b)

■ 8c. Polishing & Grinding ■

The Grinding of Milling Cutters. A. H. PREY. *Machinery,* N. Y., Vol. 42, Jan. 1936, pages 305-308. A detailed review of grinding methods with the view of obtaining best results in milling operations. Ha (8c)

Grinding Irregular Contours. *Machinery,* London, Vol. 47, Oct. 24, 1935, pages 97-98. Finish grinding of punches, dies, form tools and gages is discussed. Special shaped grinding wheels are used for precision grinding of contours. Steps in finishing are shown. WB (8c)

■ 8d. Electroplating ■

Imperfections in Electrodeposits. Studies in the Electrodeposition of Cobalt. A. CHAYBANY. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 47, Oct. 25, 1935, pages 423-426. Author has endeavored to find the causes of pores and pinholes in electrodeposits for the purpose of suppressing, if possible, their formation. The details of the study and a résumé of the results of a number of other tests by the author are described. Pure Co salt was first prepared and from it a bath. Test results are given for a neutral bath, for a bath acidified with N/5 H_2SO_4, and for a bath acidified with C.P. HF & C.P. HCl. No pin holes and very few pores were observed when deposits were tested with $K_3FE(CN)_6$. The method used to prepare a less pure salt is described. Brittle deposits, pinholes and pores were found in electrodeposits in baths prepared from this salt. Upon analysis, traces of Ni, Fe, Cu, Pb and As were found in the Co salt. The effect of As, tested by a number of different methods, was studied. The author presents a hypothesis regarding the form in which he believes the As separates from the bath. The conclusion is reached that a large number of imperfections in deposits can be attributed to the presence of feeble traces of As. HBG (8d)

Electrodeposition of Tin. A. L. SHIELDS. *Monthly Review, American Electroplaters' Society,* Vol. 22, July 1935, pages 15-34. An account of the Sn plating process used by Westinghouse for evaporator units for refrigerators. Electro Sn was chosen rather than hot-dipped Sn because of lower metal consumption, uniformity and purity of coating. Plating solution contains Na stannate 6 to 12 oz./gal., NaOH 1.75 to 2.25 oz./gal. Since anode efficiency is low, it is necessary to add metal as stannate. Periodic additions of acetic acid keep NaOH which forms from building up to a high concentration. Temperature 160° to 170° F. Cathode current density 20 to 25 $amps./ft.^2$ A deposit .0005" to .0006" thick is obtained in 30 to 35 minutes. Other operating details, and methods of analysis for Sn and NaOH are given. The plated evaporators are tested in an atmosphere of ammonia. Weak spots turn blue in a few minutes. A good deposit will stand 4 to 16 hours test before breakdown. A bibliography and 9 pages of discussion are included. GBH (8d)

A Modern Electroplating Plant. *Mechanical World & Engineering Record,* Vol. 48, Dec. 6, 1935, page 549. A new plating plant for steel products has separate departments for polishing and preparation, general plating and Cr plating and a central section which combines plating, laboratory and administration. WH (8d)

Motion of a Liquid Around an Obstacle During Electro-deposition. E. P. HARRISON & H. GOLLOP. *Natnre,* Vol. 137, Feb. 8, 1936, page 234. Stream lines are found in Cu electrodeposits when the cathode is moved through the electrolyte. The phenomenon may be used to make a permanent record of the motion of the liquid past obstacles. CSB (8d)

Microscopic Measurements of Metallic Coatings. C. E. HEUSSNER. *Monthly Review American Electroplaters' Society,* Vol. 23, Jan. 1936, pages 5-23. The microscopical method of measuring coating thickness has the following advantages: (1) measures thickness at any desired point thus disclosing the weakest area of the deposit, (2) gives absolute figures on the distribution of the deposited metal, (3) shows other properties of the deposit such as adherence to the basis metal, impurities, and porosity. The specimen, held in a clamp, is polished by usual metallographic methods. Suggested procedure: first step, rough grinding on a #50 emery wheel, at 1800 r.p.m., second step, #280 emery paper mounted on a revolving steel disc., final step, on #400 emery paper. If desired, a finish polish can be obtained on a broadcloth wheel with levigated alumina. Etching brings out the electroplated layer. If the basis metal is steel or Zn, the etchant is 3% (by vol.) HNO_3 in ethyl alcohol. If basis metal is brass or bronze, etchant is 1 part (by vol.) NH_4OH and 1 part 10% H_2O_2. The measurement is made by means of a filar micrometer eyepiece mounted in a standard microscope, at a magnification of about 500 diameters. GBH (8d)

Technological Developments in the Plating Industry. C. B. YOUNG. *Metal Cleaning & Finishing,* Vol. 7, Apr. 1935, pages 165-168. Several developments are briefly described. Electrogalvanizing of steel wire is now commercial. The pure Zn coating will not crack or peel when the wire is bent on its own diameter, and is more resistant to corrosion than hot galvanized wire. A process for increasing the corrosion resistance of Zn consists in electrolyzing Zn-plated articles in a chromic acid plating solution with low voltage a.c. The Zn becomes deep black in color. Re deposition has been accomplished from aqueous solutions. It has been deposited from a cyanide solution containing glucose. Motor oils are being marketed in cans made from steel electroplated with Cu, a product which is as durable for the purpose as Sn plate and much cheaper. GBH (8d)

Examination and Supervision of Nickel Baths and the Analyses of Salts for Nickel Baths (Die Untersuchung und Ueberwachung von Nickelbädern und die Analysen von Nickelradsalzen. I.) E. RAUB & K. BIHLMAIER. *Mitteilungen des Forschungsinstituts und Probieramts für Edelmetalle,* Vol. 9, Oct. 1935, pages 61-68. The difficulties of chemical investigation of Ni plating baths are pointed out and the factors influencing the quality of the deposits discussed. The most harmful impurities in the bath are Cu, Fe, Zn, Cd and Cr. Cu is deposited on the anode in the idle cell and gives a reddish hue to the Ni deposit. It is easily eliminated by letting the bath work for some time at low voltage. Fe is detected by citric acid. Its elimination is difficult; the best method is to precipitate it as hydroxide (see also *Mitteilungen Forschungsinstituts und Probieramts für Edelmetalle,* Vol. 8, 1935, pages 1 and 17). Zn causes streaks in the deposit and poor adhesion. It is eliminated as basic Zn salt. Cd causes similar defects and is eliminated with difficulty. The most convenient way is to dilute the bath until the harmful effect is no longer noticed; at the same time more Ni salt is added. Cr does not occur often as impurity in Ni baths but can in even very small amounts entirely prevent Ni deposition. Its elimination is difficult especially when present as chromic acid. It is eliminated as chromic salt. Oils and fats especially in colloidal form, are only eliminated by operating the bath for a longer time so that they precipitate or disintegrate. Oxidizing agents are used to correct formation of pits in the deposits. Methods for routine supervision of the correct composition of the bath are described. **The Quantitative Determination of Boric Acid and Citric Acid (Die quantitative Bestimmung von Borsäure und Zitronensäure. II.)** E. RAUB & H. NANN. Nov.-Dec. 1935, pages 77-85. Detection of boric and citric acid either alone or when present together, and the destruction of citric acid in the bath by chlorates and HCl are described in detail. Ha (8d)

Modern Filtration Practice in Electroplating. PACE. *Monthly Review American Electroplaters' Society,* Vol. 22, Dec. 1935, pages 40-48. An important phase of producing heavy deposits, such as are demanded by the automobile industry, is clarity of the plating solution. Faster plating as now done in hot, agitated solutions requires the solution to be free from suspended particles, otherwise rough and pitted work will result. A common filter used in plating rooms has been the cartridge type, with bags supported by grooved boards, a centrifugal pump being used. Recently the plate-and-frame press, with a diaphragm pump, has come into winder use for plating solutions. It has the advantage that the cloth can be cleaned by reverse flow without taking the filter apart. The diaphragm pump has the added advantages of delivering constant volume under increased pressure, requiring no priming, and being free from packing glands and stuffing boxes. It operates at low speeds. In discussing the use of filter aids it is stated that a filter precoated with hyflo-supercel will remove particles as small as .1 micron in size (about 4/1,000,000"). GBH (8d)

Silverplated Organic Materials and Shapes (Versilberte organische Stoffe und Formlinge) F. OHL. *Oberflächentechnik,* Vol. 13, Feb. 18, 1936, pages 39-40. A new process for coating paper, leather and artificial resin surfaces with a bright Ag (or Au) film depends on cathodic atomization (dispersion); 5000 m. of Ag-plated paper strip can be made in 24 hrs. The greater the initial brightness of the surface of the material to be plated, the finer is the film. Very artistic effects can be obtained by contrasts in the surface. A cellulose foil plated by this method resembles a mirror in reflected light, but is transparent to transmitted light and appears more or less blue-violet according to the thickness of the film. To cover 1 $m.^2$ requires a fraction of a gram of Ag, Au or any other metal. Ha (8d)

Chromium Plating. O. Bauer, H. Arndt & W. Krause. Translated by E. W. Parker. Longmans-Green & Co., New York, 1935. Cloth, 6 x 9 inches, 266 pages. Price $9.50.

The German edition appeared in 1934 and was reviewed on page MA 144 of Vol. 5, Apr. 1934. It covered an exhaustive study of Cr plated parts from French and American automobiles, as well as many laboratory specimens. While plating practice has advanced considerably since the 1932 or '33 cars were produced, and many of the specimens serve chiefly as horrible examples, the principles brought out still hold. The translator has greatly increased the utility of the book by added comment and new references on many points. The bibliography covers 1920 to June 1935, with 582 references and an author index to them.

Hothersall's introductory chapter summarizes the findings of the authors and ties them up with the plating procedure. It seems that Cr plating is too narrow a term, for the value of a Cr coat is overwhelmingly dependent upon the thickness, adhesion, and freedom from porosity of the Ni undercoat, so that attention needs chiefly to be centered upon making a very good Ni plate. Flashing it with Cr for tarnish-resistance is the least difficult part of the process.

The book is very much worthwhile, but the price seems exorbitant.

H. W. Gillett (8d) -B-

Plating Technique (Galvanotechnik) H. Krause. 7th Edition. Max Jänecke Verlag, Leipzig, 1936. Paper, 5¾ x 8¼ inches, 275 pages. Price 5.40 RM.

Bath compositions and current densities are given for practically all metals commercially plated, the treatment being primarily that of a recipe book, though some discussion of whys and wherefores is given. The recipes, however, include much of the more recent developments which are sufficient to justify a new edition. The 6th Edition appeared 5 years ago. As in previous editions, the author gives credit in the text to various workers mentioned by name, but fails to give specific references.

The cook-book type of plater would find the volume decidedly useful. Those who keep up with other literature in the field and who seek broad viewpoint such as might be expected in a summary of this type, may be disappointed in it.

H. W. Gillett (8d) -B-

New Methods of Nickelplating (I Nuovi Metodi di Nickelatura Moderna). E. Staurenghi. *Industria Meccanica,* Vol. 13, Aug. 1935, pages 702-704. Present Ni-plating processes are reviewed, degreasing and cleaning methods described. The Ni content of the bath is about 40-50 g./l., current density 0.3-0.4 amp./dm.^{2} corresponding to a deposition of 0.324-0.432 g. Ni/hr., while for rapid plating methods 1-3 amp./dm.^{2} are employed. The bath is stirred and the pieces are moved to prevent streaks on the deposit; pH is 5.8-6.2. For rapid Ni plating the following bath is recommended: Ni sulphate 22.5 kg., ammonium sulphate 2.0 kg., Ni chloride 0.5 kg., Na perborate 0.5 kg. (all of high purity), water 100 l., temperature 35°-40° C., voltage 2.75-3.5. Ha (8d)

Bright Electrolytic Deposits (Glänzende Metallniederschläge) Max Schlötter. *Zeitschrift für Metallkunde,* Vol. 27, Oct. 1935, pages 236-237. Bright electrolytic deposits of metals have an extremely fine grain size, of the order of the wave length of light. The size of the anions of hydrolysis products of the salts in the electrolyte is of major importance in controlling the grain size since these anions may be deposited with the metal and thereby influence the manner of grain formation. The greater the volume of the anion, the greater the rate of grain growth of the metal and the smaller the number of nuclei formed, hence, the greater the grain size. Under certain conditions, the anions (halogens, oxides, hydroxides, sulphides, etc.) may be incorporated in the deposit in appreciable quantities and directly influence the physical properties of the metal. Discussions presented by: Masing, Schlötter, Rohn, Benedicks, Sterner-Rainer, and Raub.

FNR (8d)

Differences in the Structure of Electrodeposited Metallic Coatings Shown by X-Ray Diffraction. W. A. Wood. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1248-1253. Discussion page 1259. Structural modifications indicated by X-ray spectra and their influence on the physical properties of the coatings are discussed. The effect of coldworking as shown by the breadth of any given line, for instance (311) of Ni, is a rapid increase in the early stages up to a definite limiting value with no further change. The effects of lattice distortion and selective orientation are mentioned. With the present technique, X-ray spectra are sensitive to small changes of hardness, and it appears that large changes in hardness in a given structure produce gross diffusion of the spectrum. 7 references. PRK (8d)

Factors Affecting the Structure and Grain Size of Electrodeposited Cadmium. S. Wernick. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1237-1242. Discussion page 1259. In a bath containing a negligible amount of free CN and no alkali, the deposit formed from a solution containing 8 g./l. Cd, prepared by dissolving $CdCO_3$ in KCN, was grayish white and relatively coarse-grained. With increasing Cd content, deposits showed a progressive refinement and that obtained from a bath containing 30 to 40 g./l. Cd was finely crystalline. With about 50% free CN, the deposit showed improvement in color, approaching whiteness. The macrostructure of the deposit containing 100-150% free CN showed it to be very finely grained. It is desirable to limit the free CN content to 100%. The presence of NaOH in excess of .85% aided materially in the formation of a fine grain deposit and was important in maintaining color and uniformity. 1.2-1.5% produced particularly excellent deposits. In a bath containing 30 g./l. Cd, 100% free CN and 1.5% NaOH, the deposit was white and fine-grained but became progressively grayer and more crystalline as the current density was increased above the initial value 10 amp./ft.^{2} and at 30 amps./ft.^{2} the deposit was burned. Increase of temperature of the solution above 30-35° C. caused marked deterioration of the physical properties. In solutions made from $CdSO_4$ it was found necessary to use buffers. A solution containing molar $CdSO_4$, 30 g./l. HBO_3 and N/10 NaCl, with pH range 5.5 to 6.6 produced a small grained crystalline deposit which was not comparable in refinement with that obtained from CN electrolyte. The deposit became burnishable when the current density exceeded 35 amps./ft.^{2} Treeing occurred when current density exceeded 45 amps./ft.^{2} In studying the effect of increasing temperature from 22°-80° C. a reduction in crystal size was noted up to 50° C. with simultaneous darkening of the deposit. With increasing temperature the deposit became whiter but more crystalline. Study of colloidal additions revealed that the whitest and most mat type of deposit was obtained from electrolyte containing .08-.16% gelatin. 16 references.

8e. Metallic Coatings other than Electroplating

Influence of Tinning Procedure on Pinholes in Tin Plate (Einfluss der Arbeitsbedingungen beim Verzinnen auf die Porigkeit von Weissblechen) F. Peter & G. Le Gal. *Archiv für das Eisenhüttenwesen,* Vol. 9, Dec. 1935, pages 285-291. Pinholes in tinplate depend on the surface cleanness of the prepared black sheet, the thickness of the coating, the pickling procedure, the cleanness of the flux, etc. H_2 absorbed in pickling and evolved in tinning does not appear to play an important part. Despite all precautions pinholes cannot well be eliminated in commercial tinplate. With a heavy Sn coating of 100 g./m.^{2} tinplate free from pinholes can be obtained, but only when the utmost precautions are taken.

SE (8e)

Improvement of the Quality of Sprayed Metallic Coatings by the Use of Non-metallic Intermediaries and Supports. H. Reininger. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1268-1276. Discussion page 1286. With hard brass sprayed with Ni, it was shown that soft copal varnish and bakelite varnish will penetrate into the porous structure of the sprayed metal coating and, after drying, form intermediary layers between the metal grains. The strength of the coating and its adhesion to the basis metal are increased. Metal coated in this way can be deformed plastically to a higher degree without separation of the coating from the base than if the coating has not been varnished. It is possible to grind the varnished coating practically down to the base without coating splitting off. The varnished coatings do not form galvanic elements with the basis metal and electrochemical corrosion is greatly retarded as a result.

Aluminum Coating (Aluminiumplattierung) H. G. Heine. *Korrosion und Metallschutz,* Vol. 11, Nov. 1935, pages 250-251; *Aluminium and the Non-ferrous Review,* Vol. 1, Dec. 1935, pages 85-86. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 136R/4. Ha + JCC (8e)

Influence of Surface Cuprous Oxide Inclusions on the Porosity of Hot-tinned Coatings on Copper. W. D. Jones. *Journal Institute of Metals,* Vol. 58, Feb. 1936, pages 109-116 (Advance Copy No. 727). A study of Sn coatings on Cu shows that inclusions of Cu_2O are responsible for most of the porosity. Amalgamation with Hg salts, rather than with metallic Hg, was found to be a good method for estimating probable porosity. Various methods of reducing porosity are discussed. These include cathodic treatment in caustic soda and treatment with hypophosphorous acid. The former was found to be the better. O-free Cu is recommended if non-porous Sn coatings are to be obtained. Factors Influencing the Formation and Structure of Hot-dipped Tin Coatings. Edward J. Daniels. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1277-1285. **Hot-dipped Tin Coatings.** *Sheet Metal Industries,* Vol. 9, July 1935, pages 425-428; *Mechanical World & Engineering Record,* Vol. 47, June 21, 1935, page 611. The attraction between the liquid and solid metals as a prime cause of wetting is discussed. Affinity between the basis metal and the molten coating metal results in the formation of an intermetallic compound or solid solution favoring adhesion. Additions to the molten metal sometimes alter the structure of the coating. The influence of the melting point, especially of the flux, upon the success of hot-dipping operations is discussed. The use of P in molten Sn and of H as fluxes are mentioned. The cause of the formation of ripples and spangles is discussed. 35 references. PRK + AWM + WH (8e)

Coloring of Metals. H. MacFadyen. *Monthly Review American Electroplaters' Society,* Vol. 22, Nov. 1935, pages 13-21. Describes some methods used in finishing metal parts of electrical wiring devices. Ground terminals, to be identified by Sn coating, are immersed for 20 minutes in a boiling solution containing Sn chloride 2, NaOH 2.5, and NaCN 1 oz./gal. Small studs to be given a Cu finish are first tumbled in a steel barrel with KOH to clean them, rinsed thoroughly, the water replaced with a gallon of solution containing 2 ozs. of $CuSO_4$ and 1 oz. of H_2SO_4, and the tumbling continued for ½ hr. after which they are rinsed. Galvanized Fe parts to be lacquer enameled are first treated with a 10% solution of acetic acid, rinsed in cold and then hot water and dried. This treatment results in good adhesion of the enamel to the galvanized surface. Sheet paper, fiber, and bakelite parts are waterproofed by tumbling about 40 lbs. of the work in a barrel for 20 minutes with ¼ pint Valspar varnish plus ¼ pint thinner. The pieces will not stick together if excess varnish is avoided. Steel parts covered with drawing oils are cleaned by tumbling in sawdust. It was found that potash cleaning was not necessary for this work and that it could be placed directly in the plating barrel. A black finish on steel or Fe parts is obtained by rotating 100 lbs. of the work together with ½ pint of raw linseed oil in a gas-fired retort of 650° F., for 1½ hrs. Upon removal, the work is dipped in raw linseed oil and dried in a centrifugal dryer. GBH (8e)

Metal Spraying in the Welding Shop. H. B. Rice. *Welding Engineer,* Vol. 21, Jan. 1936, pages 34-42. Metal spraying as a means of repairing and building up worn pieces is described and illustrated. In some cases spraying is preferred to welding as less metal is needed and a continuity of galvanized surfaces can be obtained by spraying Zn on welded areas. The C content in the welding or spraying rod is reduced more in spraying than in welding, 20-40% C is lost in the spraying process. Many examples in railroad and engine building practice are described. Ha (8e)

The Development and Control of Spangles on Galvanized Iron. Part 3. W. G. Imhoff. *Metal Cleaning & Finishing,* Vol. 7, Apr. 1935, pages 173-177. Small granular spangles are caused by the steel becoming oxidized. The fuel-air mixture for the soaking pit firing should be non-oxidizing. Overheating should be avoided. GBH (8e)

8f. Non-Metallic Coatings

Oxidation Films on Aluminum and Its Alloys; Their Production and Properties (Pellicules d'oxydation sur l'aluminium et ses alliages; leur production et leur propriétés) A. G. C. Gwyer & N. D. Pullen. *Revue de Métallurgie,* Vol. 32, Dec. 1935, pages 658-667. Films produced by anodic oxidation of Al have either high or low resistance to current. The former are used principally in electric apparatus. The latter are employed for corrosion protection and for colored Al ware. The color, hardness, electrical resistance, composition, etc. of the films vary widely with the nature of electrolyte, its concentration, temperature, current used, etc. A series of tests is proposed for the determination of the desired properties of these films. Aluminum alloys with 3, 6, 9, and 12% Cu, 13% Zn and 10-12% Si were studied metallographically after anodic treatment in chromic, sulphuric and oxalic acid solutions respectively. In chromic acid, Cu content of 9% prevents the formation of a uniform film. The metal is oxidized along Cu inclusions. The same effect occurs in H_2SO_4 solution. In oxalic acid 12% Cu does not interfere with a continuous film formation. In none of these solutions does 13% Zn disrupt the continuity of the film, nor does 10-12% Si. Operating data and 30 photomicrographs are given. JDG (8f)

Progress Made in Surface Treatment and Finishing of Aluminum. R. T. Griebling. *Steel,* Vol. 98, Mar. 23, 1936, page 50. Describes briefly painting of Al and the Alumilite and Alzak finishing processes for Al. MS (8f)

Processing of Enameled Wire. *Industrial Heating,* Vol. 3, Mar. 1936, pages 185-186. Heat treatment of wire to be enameled, and process itself and equipment for it are described. Ha (8f)

Paint Films of Controlled Thickness. H. G. Arlt. *Bell Laboratories Record,* Vol. 14, Mar. 1936, pages 216-217. An automatic spraying machine was developed for producing paint films of absolute uniformity so that reliable measurements of physical properties, corrosion resistance, etc. can be made. A uniformity of 1/10000" over the entire area (except the marginal zones) can be obtained. Ha (8f)

Effect of Mill Practice and Mill Additions on the Opacity of Enamels. G. L. Bryant & F. R. Porter. *Journal American Ceramic Society,* Vol. 19, Feb. 1936, pages 55-59. Tests showed that fine grinding increases opacity but the effectiveness is variable with different enamels so that with some the cost of fine grinding offsets added benefits. SnO up to 6% increases opacity in frit blends studied and type of clay added to mill batch has an important effect on opacity of the enamels. Effect on opacity depends on whether SnO is added at end or beginning of mill batch. Addition of feldspar to some of the enamels increases opacity either by preventing solution of SnO in enamel glass or by undissolved feldspar. Some SnO substitutes are as effective as Sn oxide with certain frit compositions. WB (8f)

Aluminium Paint as a Primer. *Aluminium & the Non-Ferrous Review,* Vol. 1, Oct. 1935, page 21. Brief account of tests by Forest Products Laboratory of the U. S. Department of Agriculture on aluminium paint as a primer on woods in house painting. JCC (8f)

Protective Paint Coats on Aluminum (Schutzanstriche auf Aluminium) *Oberflächentechnik,* Vol. 13, Feb. 4, 1936, pages 29-31. Although the natural film on Al is often quite sufficient for protecting Al parts against atmospheric and other attacks, a more protective coat is sometimes required. If a coat of paint is to be applied the natural oxide film must first be removed, by pickling in NaOH solution of 10-25%, sandblasting, treating with emery paper, or Cu plating. Such coats must not contain alkaline constituents or acid residues such as Na silicate, Ca, basic pigments, Fe oxide red, as they react with the Al; also red Pb cannot be recommended. Bitumen and chlor-caoutchouc coats are not very reliable. Ti white in oil, polymerizations of organic, non-saturated fatty acids both mixed with other lacs or in nitrocellulose are very effective. Lately, phenol resins have been applied with good success. Conditions, both favorable and unfavorable to the application of these materials as protective coating on Al are discussed. Ha (8f)

Protective Materials in Use for Outdoor Structural Work. *Steel,* Vol. 98, Feb. 24, 1936, pages 42-43. Metal protective paints should contain no pigments which form H_2O-soluble compounds or promote chemical action within dried paint film. For maximum durability, there should be about 30% by volume of opaque pigment in the dried paint film of the priming coat. Good primers are basic $PbCrO_4$, Pb_3O_4, and basic $PbSO_4$. Chemical surface treatment prior to painting is recommended. MS (8f)

Eliminating the Blistering of Enamels on Cast Iron. H. D. McLaren. *Steel,* Vol. 97, Dec. 30, 1935, pages 25, 40. From *Enamelist,* Vol. 12, July 1935, pages 6-7, 46, 60. See *Metals & Alloys,* Vol. 6, Dec. 1935, page MA 500R/8. MS (8f)

Painting on Copper (La Peinture sur Cuivre). J. Meyral. *Cuivre et Laiton,* Vol. 8, Nov. 15, 1935, pages 471-474. Cu is an excellent base for oil paints, preferable to Fe and Zn. Coats of paint are more durable on Cu in the open air than on other metals. Procedures are described. Ha (8f)

Aluminium Powder as a Metal Finish. *Aluminium & the Non-Ferrous Review,* Vol. 1, Oct. 1935, pages 19-20. Vehicles for aluminium paints and their uses are discussed. Mica is an objectionable adulterant and is detected as a residue remaining after dissolving sample in HCl. JCC (8f)

Cracking of Enameled-Iron Edges (Ueber das Abspringen der Emailränder). Richard Aldinger. *Keramische Rundschau,* Vol. 43, Jan. 17, 1935, pages 25-28. Discusses theoretically the causes of flaking and cracking of enameled metal ware. Stress conditions are most important, and are affected by differential expansion of Fe and the enamel, and by the position of the enamel on the interface curvature. Defects in the enamel, production faults, and flaws in the underlying metal are systematically classified and their effects on the cohesion and adhesion of the enamel discussed. FPP (8f)

9. TESTING

9a. Inspection & Defects, including X-Ray Inspection

C. S. BARRETT, SECTION EDITOR

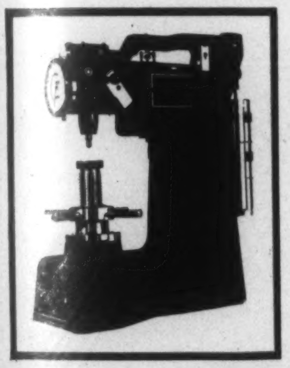
Electrical Engineering in Radiology. L. G. H. SARSFIELD. Instruments Publishing Company, Pittsburgh, 1936. Cloth, 5½ x 8¾ inches, 276 pages. Price $6.00 postpaid.

The volume of business involved in the manufacture of medical and industrial X-ray apparatus in late years is considerable, and has justified the maintenance of active research and development laboratories by a number of concerns. These have put on the market an extensive and diversified array of X-ray tubes, rectifiers, transformers, voltage regulators, condensers, cables, control gear, etc. While books on X-ray radiology, radiography and diffraction have explained the fundamental principles of this art, they have had space for no extensive discussion of the requisite equipment. Thus there is a definite place in the world for a book dealing, as this one does, with the design, testing, operation and maintenance of these devices. The author is well equipped to write authoritatively, as he has had a number of years' experience in the radiological research laboratory at Woolwich. He discusses a number of tests and experiments he has made and includes some detailed designs of transformers that he has built. He is familiar with apparatus manufactured on the continent and in America and has not limited the book to British apparatus.

Most of the book is presented in a common-sense fashion easily understood by anyone, only a relatively small portion of the book requiring familiarity with the more technical concepts in electrical engineering.

Research laboratories will find particularly useful the full discussion of voltage-multiplying circuits and constant-potential circuits, the data on designs of high-voltage transformers, filament transformers and bushings for high-voltage insulation, and the discussions of operating characteristics. There are numerous references to the literature for more detailed accounts. C. S. Barrett (9a) -B-

Inspection, Testing and Gages at the Ford River Rouge Plant. *Mill & Factory,* Vol. 18, Jan. 1936, pages 172-182. The effect of Ford's application of precision methods on the constantly closer tolerances in evidence throughout the automobile industry is discussed. Inspection devices that make possible 3030 parts (in one car) manufactured to tolerances less than .005" include 93 visual gages, a master gage system of Johansson blocks, special automatic camshaft sizing machines, fatigue, shock, bend, torsion testers, distributor timing gage, recording gasoline flowmeter, etc. Rooms are air-conditioned to increase precision. FPP (9a)



Do you desire to test sheet or strip metal of only .008" to .040" for hardness?

Thin sheet metal and nitrided or lightly carburized steel presents a very special problem, because any indentation hardness test is influenced by the hardness of the metal to 10 or 15 times the actual depth of indentation.

We have developed a special form of our "ROCKWELL" Hardness Tester for that work. Tell us your problem.

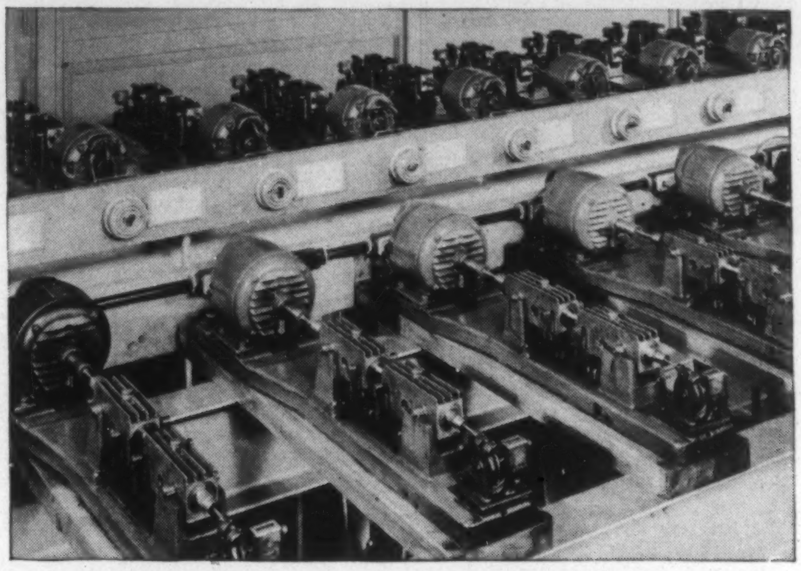
Leadership in TESTING methods and equipment



The Phenomena of Fatigue

Many perplexing problems of the failure of machine parts to withstand service conditions are now being solved by the "repeated stress" or "fatigue test."

Research has shown that the fatigue test discloses factors shortening the life of materials in service which cannot be revealed by tension, hardness, ductility, impact, or other routine tests. For failures in service seldom occur under the application of a single stress which approaches the ultimate strength of the material.

Such failures usually occur after the repeated application of stress below the ultimate strength of the material. Such failures are progressive, due to the development, growing and spreading of fine cracks—the final rupture occurring with no warning and with practically no deformation of the metal.

Problems which involve the comparison of effects of various factors upon the value of metals as structural materials, always therefore, should consider the effect on the result of the "repeated stress" or "fatigue test." Such factors as chemical composition, mechanical treatment, heat treatment, corrosion, methods of joining, sudden changes in section, affect the metal more severely under repeated stress than under a single application of a gradually increasing stress.

To closely approach service conditions in a fatigue test, accommodating actual full-size machine shafts and other parts, and reproducing years of service in a few days, the R. R. Moore Fatigue Testing Machine was developed. It soon became the recognized standard. Today hundreds are in use in practical investigation in many well-known manufacturing plants and research laboratories.

Bulletin No. 96, describing this machine, will be sent on request.

Results of Technical X-ray Science. Vol. V. Commercial Applications of the Radiographic Method (Ergebnisse der technischen Röntgenkunde. Band V. Anwendungen der Durchstrahlungsverfahren in der Technik) J. Eggert & E. Schiebold. Akademische Verlagsgesellschaft, Leipzig, 1935. Cloth, 6¼ x 9¼ inches, 118 pages. Price 15 RM.

This latest volume of the series is strictly limited in scope, dealing only with radiography, and is smaller than the previous volumes. It is not intended as a handbook or a textbook on radiography (the fundamentals have already been treated in numerous books including earlier volumes of this same series); it is, rather, a collection of short papers by the users of the method, telling what it has been able to do for them in their special fields. For example, there is a chapter on aircraft applications which discusses the testing of wooden parts, both with X-rays and with a 2000 watt light (the latter penetrates thicknesses up to 2½ mm.); the radiography of various kinds of metal parts, including castings, welded joints, and locating cracks by radiography and by other non-destructive methods; the effect of defects on the strength of parts; and the detection of faulty assembly of parts. Each paper includes a short note on the apparatus most suitable and on whether or not gamma-rays are satisfactory for that particular type of work. That Germany is making wide use of radiographic testing is shown by the list of fields in which successful application is reported: aircraft; marine equipment, including ships' boilers, Diesel motor parts, torpedo equipment, high pressure tanks and tubing, and propellers; railroad equipment, such as locomotive boilers, high pressure vessels, welded beams, parts of railway turntables, reinforced concrete structures; welded bridges; pressure vessels for the petroleum industry; and the detection of internal corrosion and breakage in steel cables. Several of the authors of these chapters state that they have been using X-rays for several years and have come to consider them indispensable.

Some recent developments in technique are described and their advantages discussed: the use of filters and wedges made of tin and placed between specimen and film to remove scattered rays and to equalize exposures; the development of a method for exposing greater lengths of welds in a single exposure by placing a high voltage tube at a distance of several meters from the work; the use of flexible high voltage cables, 30 to 60 feet long, connecting the transformers to portable tubes; and new designs in tubes, tube mountings, and film holders. Ten different authors have contributed papers; there are in all 87 references, of which 81 are to German literature. The papers contain numerous cross-references and are well illustrated with photographs and radiographs; exposure data are given for all radiographs that are printed. C. S. Barrett (9a) -B-

Autogenous Welding (Soudure autogène) R. Schmidt. *Usine*, Vol. 45, Mar. 19, 1936, page 29. The radiography of welds and the application of X-rays for their examination are explained. A radiograph of a piece of 20 mm. thickness can be obtained with 100,000 v., of 80 mm. with 200,000 v., and of 140 mm. with 400,000 v.; the time of exposure is less than 1 min. The limitation of the method in recognizing defects is discussed. Ha (9a)

Strength of Scattered radiation in Radiography (Stärke der Streustrahlung bei Röntgendurchstrahlung) O. Vaupel. *Archiv für das Eisenhüttenwesen*, Vol. 9, Oct. 1935, pages 213-214. The aim was to protect operators of X-ray machines from stray radiation. The effects of distance of the operator from the radiated object, of the angle of the scattered beam with the primary beam, size of the radiated surface, distance of X-ray tube from the surface, and X-ray voltage, were studied. A formula is given by which the strength of X-ray dosage at different locations can be calculated. SE (9a)

Calculation of the Elongation in a Tensile Test for Various Gage Lengths (Umrechnung der im Zugversuch ermittelten Bruchdehnung auf andere Probenmesslängen) W. Kuntze, F. Uebel & F. Gentner. *Archiv für das Eisenhüttenwesen*, Vol. 9, April 1936, pages 509-523. A comprehensive discussion of this problem. Curves are given whereby the elongation for any gage length can be calculated, when the elongation for a certain gage length is obtained. SE (9b)

On the Modulus of Elasticity of Wire Ropes. B. M. Suslov. *Wire & Wire Products*, Vol. 11, Apr. 1936, pages 176-182. Present practice in Russia of manufacture of wire rope and cables is shown and methods of determining structural and elastic elongation explained. The modulus of elasticity depends on number of strands, number and diam. of wires in a strand, material of center (hemp or metallic), type of stranding, physical nature of a rope (new or old), wire material, degree of wear, and degree of prestressing in the manufacturing process or in service. The tests permit the conclusion that in order to have high modulus wire ropes, it is necessary to use multiple stressing of new ropes, or to use old used ropes for this purpose. This confirms previous results by Sunderland (*Engineering News Record*, Mar. 7, 1930). Ha (9b)

Effect of the Springing of a Tensile Machine on the Stress-Strain Curve (Einfluss der Federung der Zerreissmachine auf das Spannungs-Dehnungs-Schaubild) W. Späth. *Archiv für das Eisenhüttenwesen*, Vol. 9, Dec. 1935, pages 277-283. A tensile machine consists of a combination of springs and weights. In static loading the stress-strain curve depends on the self-springing of the machine. The harder the springing the more sensitively it records the fall in stress on plastic yielding. With soft springing the stress may remain constant during plastic flow. It is suggested that the "lower yield point" results from the springing characteristics of the machine rather than from the characteristics of the material. This is disputed in the discussion. SE (9b)

Research on Yield Limits and the Tensile Strength of Mild Steel and Other Metals. G. Welter. *Metallurgia*, Vol. 13, Jan. 1936, pages 89-92. The lower yield point and the drop in stress after the maximum stress has been reached in ordinary tensile testing have no significance because they depend on the machine and not the test piece. Stress-strain curves made with dead loading are given to prove that as a specimen is gradually stretched the unit stress never decreases. It is suggested that tensile machines should be redesigned so that in spite of rapid elongation of a specimen the load will not decrease. JLG (9b)

Present Position of the Cast-Iron-Test-Bars. *Foundry Trade Journal*, Vol. 53, Aug. 29, 1935, pages 146-147. Discussion of paper on "Relationship in Cast Iron Test Results" by Harbach (see *Foundry Trade Journal*, Vol. 53, July 25, 1935, pages 61-63; Aug. 1, 1935, pages 85-87; abstracted in *Metals & Alloys*, Vol. 7, Mar. 1936, page MA 139L/2). J. G. Pearce pointed out that it was shown in his laboratory some years ago that, other things being equal, a round bar was always stronger than a square bar. That difference had nothing to do with casting conditions, because it remained true even if the square bar was made from one which was originally cast round, and if the round bar was made from one originally cast square. The difference was due, probably, to the manner in which the stress distributed itself across the section of the bar. The result was that the 2" by 1" bar broken at 36" centers broke at a load almost identical with the 1.655" bar at 24" centers if the latter were made a little bit smaller. If it were made 1.6" instead of 1.655" the loads should be about the same. The difference was, roughly, about 10%. This suggested that a very convenient range might be obtained for bars for testing purposes if, say, there were diameters of 0.8", 1.2", 1.6" and 2", each tested at a span equal to 15 dias., respectively, 12", 18", 24" and 30". Those 4 bars have diameters with ratios of 1, 1½, 2, 2½, and the ratios of the areas were roughly, 1, 2, 4 and 6. John Shaw is of the opinion, based on many experiments, that the bar should be as short as would yield a reasonable deflection. This was lately confirmed by J. T. Mackenzie, who found little difference in the deflection of the 2" bar when tested either at 18" or 24" centers. AIK (9b)

The Elements of the Theory of Strain Energy. R. J. Cornish. *Structural Engineer*, Vol. 14, Mar. 1936, pages 160-161. The main principles underlying the strain energy theorem are summarized briefly. Assuming elastic materials the author cites application of the theorem to direct stress, bending, shear, torsion and total strain energy problems. FPP (9b)

Heat Evolved During the Tension Testing of Steel (Untersuchungen über die Wärmetönung beim Zugversuch mit Stahlproben) H. Esser, H. Cornelius & W. Banck. *Archiv für das Eisenhüttenwesen*, Vol. 9, Apr. 1936, pages 529-533. A very accurate flow calorimeter was devised for determining the heat evolved during the tension testing of steel. The latent heat during elastic deformation increased with increasing C content. Raising the Cr content decreased the latent heat in ferritic steel more than in austenitic. Ni raised the latent heat more in austenitic steels. The state of heat treatment had little effect. An increase in latent heat occurred above the yield strength, soon reached a maximum, and decreased again as necking down began. SE (9b)

Rockwell and Vickers Apparatus for the Determination of Hardness (Gli Apparecchi Rockwell e Vickers per la Determinazione della Durezza: (Rc); (Vp)) A. Golassini. *Industria Meccanica*, Vol. 19, Mar. 1936, pages 117-127; Apr. 1936, pages 187-194. The principles of hardness measurement by the methods of Rockwell and Vickers are explained, the manner of their application and which to select, and their numerical relations are described at length. Examples illustrating advantages and modes of application are given. Ha (9b)

9c. Fatigue Testing

H. F. MOORE, SECTION EDITOR

The abstracts appearing under this heading are prepared in cooperation with the A.S.T.M. Research Committee on Fatigue of Metals.

Fatigue of Metals. H. J. GOUGH. *Proceedings Staffordshire Iron & Steel Institute,* Vol. 50, Session 1934-35, pages 74-97. 19 references. A discussion of some of the more recent developments of interest. I. The new machines. (a) Fatigue machine of Dowling, Dixon and Hogan, for testing wire, (b) fatigue machine for testing wire by Haigh and Robertson, (c) high frequency machine of Krouse, (d) combined stress fatigue stress testing machines, (e) N.P.L. machine for testing plates, also riveted and welded joints under boiler conditions. II. Corrosion—Fatigue. A fairly extensive program of work on the corrosion-fatigue characteristics of commercial materials is in progress at the National Physical Laboratory. III. Fatigue testing of full-sized components. (a) Tests on drill pipe and pipe joints, (b) some current Swiss experiments, (c) tests on metal air-screws, (d) tests on lifting gear, (e) tests on riveted and welded drums. IV. Fatigue tests at low temperatures. V. Suggested accelerated method for determining the fatigue limit. VI. Fatigue as a fundamental problem. VII. International Cooperation directed towards the study of materials of construction. GTM (9c)

Some Further Experiments on Atmospheric Action in Fatigue. H. J. GOUGH & D. G. SOPWITH. *Journal Institute of Metals,* Vol. 56, No. 1, 1935, pages 55-89. See *Metals & Alloys,* Vol. 6, Feb. 1935, page MA 67L/1. (9c)

Corrosion-fatigue Properties of Duralumin With and Without Protective Coatings. I. J. GERARD & H. SUTTON. *Journal Institute of Metals,* Vol. 56, No. 1, 1935, pages 29-53. Includes discussion. See *Metals & Alloys,* Vol. 6, Feb. 1935, page MA 65L/3. (9c)

Fractures Without Deformation in Boiler Parts (Verformungslose Brüche an Kesselteilen) W. RUTTMANN. *Zeitschrift Verein deutscher Ingenieure,* Vol. 79, Dec. 28, 1935, pages 1561-1564. Fractures without deformation are in general due to pure endurance fractures without corrosion, or corrosion fatigue fractures, and intercrystalline fractures, i.e. fractures in the grain boundaries. Recent investigations showed, however, that not every fracture without deformation is due to fatigue. For fractures in boilers, in particular, it can be stated that fractures in flanges are usually due to vibration or corrosion-vibration fatigue, but that cracks around rivet holes can by no means be ascribed to fatigue, but must rather be ascribed to some, as yet unexplained static stress, possibly to chemical action as indicated by the investigations of Straub and by Schroeder and Berk. 18 references. Ha (9c)

The Strength of Metals Under Combined Alternating Stresses. H. J. GOUGH & H. V. POLLARD. *Mechanical World & Engineering Record,* Vol. 9, Nov. 22, 1935, pages 501-502; Nov. 29, 1935, pages 527-528, 536; *Engineering,* Vol. 140, Nov. 8, 1935, pages 506-508, 511-513; Nov. 15, 1935, pages 541-542; Nov. 22, 1935, pages 565-567. Paper before the Institution of Mechanical Engineers. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 25R/2. WH + LFM (9c)

The Cast Crankshaft (Die Gusskurbelwelle) A. THUM & K. BANDOW. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, Jan. 4, 1936, pages 23-27. Fatigue bending and torsion tests with crankshafts of (forged) steel, malleable casting and pearlite casting have shown that for all constructions, the fatigue bending strength is lower than the fatigue torsion strength. (Note by H.F.M. This is probably due to the fact that under repeated or reversed torsion cast iron fails by diagonal tension rather than by shear. The diagonal tensile stress in torsion is equal to the shearing stress and cast iron is usually stronger in shear than in tension). It is possible to increase the fatigue strength of cast crankshafts considerably by correctly shaping them so that they become almost equal to forged steel. The advantage of a cast crankshaft is that the freedom in giving it a proper shape is much greater than for forging, weights can be reduced and cost, especially in quantity production, lowered. 15 references. Ha (9c)

9e. Spectrography

Spectrographic Determination of Arsenic, Phosphorus, and Sulphur in Metals, Especially in Platinum (Spektralanalytische Bestimmung von Arsen, Phosphor und Schwefel in Metallen, besonders in Platin) W. ROLLWAGEN & K. RUTHARDT. *Metallwirtschaft,* Vol. 15, Feb. 21, 1936, pages 187-189. The methods are developed for the semi-quantitative analysis of P and As in Pt, as little as 0.005% being detectable by means of a flashing arc. About 0.05% S can be shown by a condensed discharge in a Geissler tube. GD (9e)

Quantitative Spectral Analysis of Aluminum Alloys (Quantitative chemische Spektralanalyse von Aluminiumlegierungen) G. SCHEIBE & A. SCHÖNTAG. *Metallwirtschaft,* Vol. 15, Feb. 7, 1936, pages 139-141. The visual analysis of Al alloys with the spectroscope is made difficult by the scarcity of Al lines. However, with a standardized electrode arrangement and constant current it is possible to use lines from the atmosphere when calibrated against known samples. Si, Cu, and Na were determined in this way with an accuracy satisfactory for control work. By using one Cu electrode Mg was determined. Mg, Si, Mn were determined photographically by comparison with Al lines. Attempts to determine Fe were not successful. For all spectroscopic work with Al alloys it is important to have specially prepared small chill castings to avoid segregation. The electrodes must not be overheated or they will react too much with the air. The accuracy of photometric analysis is twice that of visual, but it requires hours as compared to minutes for the visual. GD (9e)

10. METALLOGRAPHY

J. S. MARSH, SECTION EDITOR

A Redetermination of the Parameter of Hauerite, MnS_2. FRANKLIN OFFNER. *Zeitschrift für Kristallographie,* Vol. 89, Oct. 1934, pages 182-184. (In English.) By means of Laue photographs a parameter of 0.4012 ± .0004 A. U. was found. The S—S distance is 2.086 ± .008 A. U. yielding a bond radius for S of 1.043 ± .004 A. U. which is in good agreement with the value determined by Pauling & Huggins. The anomalous radius of 1.55 A. U. for Mn is confirmed. EF (10)

Structural Determinations of Complex Sulphides (Ergebnisse der Strukturbestimmung komplexer Sulfide) WILHELM HOFFMANN. *Zeitschrift für Kristallographie,* Vol. 92, Dec. 1935, pages 161-185. The arrangement of the S and metal atoms in the sulphides and S salts of As, Sb and Bi are discussed. Further information on the previously described structures of the $CuSbS_2$ and SbS_3 structural types is given. EF (10)

The NiS and NiSe Structure and Their Variations (Strutture ed alterazioni di struttura di NiS e di NiSe) G. R. LEVI & A. BARONI. *Zeitschrift für Kristallographie,* Vol. 92, Dec. 1935, pages 210-215. In Italian. γ NiS is identical with Millerite: rhombohedral, a = 9.61 A.U., c = 3.15 A.U.; c/a = 0.32 β NiS is identical with the known synthetic NiS preparations; *i.e.,* hexagonal with a = 3.42 A.U., c = 5.30 A.U., c/a = 1.55 α NiS is amorphous and undergoes some changes in air but does not become crystalline. The transformation γ NiS → β NiS was studied by electron interferences. The structures of NiSe are completely analogous to the corresponding NiS structures. EF (10)

Precise Determination of the Lattice Constant of Silicon (Präzisionsmessung der Gitterkonstanten von Silizium) M. C. NEUBURGER. *Zeitschrift für Kristallographie,* Vol. 92, Dec. 1935, pages 313-314. Si of 99.84% purity (bal. 0.1% N, 0.027% Fe, 0.014% Ca, 0.008% Al, 0.004% C, 0.002% O and trace of H) was investigated. The lattice parameter is a = 5.4173 ± 0.0005 A.U. at 20° C. (On the same material, the determination of JETTE & FOOTE, *Journal of Chemical Physics,* Vol. 3, 1935, pages 605-616, gave a = 5.41982 ± 0.00034 A.U. at 25° C.—Abstractor). Using an atomic weight of 28.06, the density of Si was calculated to be 2.327, atomic radius = 1.173 A.U. EF (10)

Lattice Constant and Allotropy of Beryllium (Gitterkonstante und Allotropie von Beryllium) M. C. NEUBURGER. *Zeitschrift für Kristallographie,* Vol. 92, Dec. 1935, pages 474-475. Contrary to previous determinations by Owen, Pickup, & Roberts *(Zeitschrift für Kristallographie,* Vol. 91, 1935, pages 70-76) who found a = 2.2812 A.U., c = 3.5781 A.U. and c/a = 1.5685, the redetermination of Neuburger yielded a = 2.2680 ± 0.0003 A.U., C = 3.5942 ± 0.0004 A.U., c/a = 1.5847 at 20° C. using a metal with only spectroscopic traces of Fe, Ba and C. The considerable deviation between these determinations is ascribed to the impurities present in the Be (99.75%) utilized by the British investigators and to the allotropy of Be. The $\alpha \rightarrow \beta$ transformation occurs between 500° and 600° C. and is considerably delayed on cooling. The material used by Owen and coworkers was annealed previous to X-raying. EF (10)

Precision Determination of the Lattice Constant of Highly Pure Columbium (Präzisionsmessung der Gitterkonstanten von sehr reinem Niob) M. C. NEUBURGER. *Zeitschrift für Kristallographie,* Vol. 93, Jan. 1936, pages 158-159. Cb prepared by Burgess & Basart (See *Zeitschrift für anorganische & allgemeine Chemie,* Vol. 216, 1934, pages 223-227) yielded a = 3.2941 ± 0.0003 A.U. at 20° C. The density derived therefrom is 8.569 and the atomic radius is 1.4264 A.U. EF (10)

Precision Determination of the Lattice Constant of very Pure Tantalum (Präzisionsmessung der Gitterkonstanten von sehr reinem Tantal) M. C. NEUBURGER. *Zeitschrift für Kristallographie,* Vol. 93, Mar. 1936, pages 312-313. Previous determinations are reviewed. Ta prepared by Burgers & Basart (See *Zeitschrift für anorganische & allgemeine Chemie,* Vol. 216, 1934, pages 223-227) gave a = 3.2959 ± 0.0003 A.U. at 20° C. Density = 16.655. EF (10)

Lattice Constants for 1936 (Gitterkonstanten für das Jahr 1936) M. C. NEUBURGER. *Zeitschrift für Kristallographie,* Vol. 93, Jan. 1936, pages 1-36. Comprehensive survey. Lattice constants for 1936 including data on atomic weights, density, number of atoms per unit cell, lattice parameter, shortest interatomic distance, atomic radius, atomic space, density of packing, volume of atom, transformation temperature are tabulated. Periodic system. Radii according to Goldschmidt. A special table presents detailed information on the purities of elements investigated, which represents an interesting account of the advance in the preparation of highly pure elements. 140 references. EF (10)

Question of Picture Size in Photomicrographic Work on the Metal Microscope (Zur Frage des Aufnahmeformates bei mikrophotographischen Arbeiten am Metallmikroskop) ERNST ROSSOW. *Zeitschrift für Metallkunde,* Vol. 27, Nov. 1935, pages 263-264. The 35 mm. micrographic camera is compared with the common bench-type metal microscope: (1) enlargements of 35-mm. negatives show resolution nearly equal to that on plates taken directly with the larger microscope provided that a fine-grained film is used; (2) cost of operating the 35-mm. camera is low both in actual cost of materials and in cost of labor; and (3) the speed of operation of the 35-mm. camera is much greater. FNR (10)

Roentgenographic and Electric Investigation of Pd-Ag-H alloys (Röntgenographische und elektrische Untersuchung der Pd-Ag-H-Legierungen). G. ROSENHALL. *Annalen der Physik,* Series 5, Vol. 24, Oct. 1935, pages 297-325. The Pd-Ag-H diagram was established. An unexpected change of resistance was found which lasts a fairly long time before equilibrium is attained. Pd-Ag alloys have a particular aptitude to absorb H; it could, however, not be determined definitely whether the H atoms are embedded in the interstices of the Pd-Ag lattice or if metal and silver-like Pd-H atoms are distributed on the face-centered lattice points. The electric measurements seem to support the latter hypothesis. Ha (10)

Kinetics and Mechanism of the Allotropic Transformation in the Palladium-copper System (Kinetik und Mechanismus der allotropen Umwandlung im System Palladium-Kupfer) L. Graf. *Physikalische Zeitschrift*, Vol. 36, July 15, 1935, pages 489-498. The course of the allotropic transformation in Pd–Cu system has been studied by X-rays and microscopically on single crystals containing 40-50 at. % Pd. A 2-phase transformation has been noticed whereby the β crystals decompose into a polycrystalline structure of a certain transformation texture. The latter was thoroughly investigated and geometrically established. It is assumed that decomposition of the β crystals starts from the energetically most unstable planes and that certain planes of the α crystals build up from the liberated atoms in an orientated position with reference to the β crystals (similar to the conditions prevailing in heteropolar crystals). EF (10)

Constitutional Diagram and Magnetic Properties of Platinum-iron Alloys (Zustandsdiagramm und magnetische Eigenschaften von Platin-Eisen-Legierungen) L. Graf & A. Kussmann. *Physikalische Zeitschrift*, Vol. 36, Aug. 15, 1935, pages 544-551. In a series of Pt–Fe alloys whose structure was determined by miscroscope and X-rays, the following observations were made on the Fe side of the binary system, the saturation magnetization increases due to the addition of Pt to Fe by about 10% and then drops again owing to the appearance of the face-centered crystals. Structural peculiarities of the α phase were not noticed. At 26 at. % Pt, the alloy consists almost entirely of γ crystals and is no longer ferromagnetic. Between 30 and 70 at. % Pt, strong ferromagnetic effects (Curie point up to 450°C. were again found due to the occurrence of the face-centered cubic γ solid solution which changes into the still ferro-magnetic compound FePt below 1200°C. FePt is body-centered cubic (with $a = 2.88$ A.U. and without superstructure) and has a Curie point which is 100°C. higher than, and a saturation magnetization different from, that of the solid solution of the same composition. In this concentration range, all Fe-Pt alloys exhibit an extraordinarily wide hysteresis loop with coercive forces up to 1800 oersteds and a remanence of 3000-4000 c.g.s., which represents the highest values of magnetic energy content known so far. The reason for the widening of the loop is the considerable lattice distortion due to the mechanism of the transformation from solid solution to intermetallic compound lattice, a mechanism comparable to that of martensite transformation. EF (10)

The Calculation of Potential Distribution in Certain Crystal Lattices. W. E. Laschkarew & A. S. Tschaban. *Physikalische Zeitschrift der Sowjetunion*, Vol. 8, No. 3, 1935, pages 240-254. In English. The "equivalent" atoms for the lattices of Li, Al, NaCl and C (diamond) have been computed. The potential distribution for some planes of these crystals has been evaluated. EF (10)

Structure of a Deformed Crystal and the Recovery Phenomenon (Der Bau eines deformierten Kristalls und die Erholungserscheinung) M. Kornfeld. *Physikalische Zeitschrift der Sowjetünion*, Vol. 7, No. 5/6, 1935, pages 608-618. The previously presented experimental evidence (See *Metals & Alloys*, Vol. 5, page MA 455 R-6, Vol. 5, page MA 578 L-8, Vol. 6, page MA 504 R-3) is re-interpreted and discussed together with data on recovery of metallic materials as established by other investigators. According to the author's hypothesis, the larger portion of the latent energy induced in a metal by cold working is located at the interfaces of dislocated "blocks," i. e. at the boundary planes along which slip takes place. The smaller portion of the cold work energy is consumed in elastic distortion of the space lattice. The elimination of the strain hardening effects due to cold work is closely connected with irreversible changes in the boundary regions of the "blocks" and are due either to the abolishment of the more severe distortions or to the complete disappearance of some boundary interfaces. EF (10)

Crystal Structure of Aluminum Compounds of the Spinel Type and of γ-Fe_2O_3 (Kristallchemische Untersuchungen über Aluminiumverbindungen mit spinell-artigem Gitterbau und über γ-Fe_2O_3). Ernst Kordes. *Zeitschrift für Kristallographie*, Vol. 91, Sept. 1935, pages 193-228. Based on a structural interpretation of γ Al_2O_3, a new explanation for the structure of ferromagnetic γ Fe_2O_3 is offered. EF (10)

The Electronic Structure of Diamond. George E. Kimball. *Journal of Chemical Physics*, Vol. 3, September 1935, pages 560-564. The method of Wigner & Seitz, as extended by Slater, has been applied to diamond, chosen as the most typical non-metallic crystal with the object of explaining the characteristic differences between metals and non-metals. It was found that the energy levels of the C atom are broadened into bands similar to the energy bands in metals. The lack of electrical conductivity is explained and other properties of the diamond are discussed. EF (10)

The Structure of Electrolytic Oxide Layer on Aluminum. E. J. W. Verwey. *Zeitschrift für Kristallographie*, Vol. 91, Sept. 1935, pages 317-320. In English. The structure of cubic γ' Al_2O_3 formed by electrolytic oxidation of Al is described as an average structure of the ratios. The unit cell contains 4 O ions in face centered positions; 2⅔ Al^{3+} ions are distributed statistically over all the interstices between the O^{2-} ions in such a way that 70% of the A^{3+} ions have coordination number 6 and 30% a coordination number 4 with regard to the oxygen. γ Al_2O_3 and γ' Al_2O_3 are intermediate cases between the amorphous and completely arranged state. EF (10)

Rolling and Recrystallization Structure of an Iron-nickel Alloy (Ueber die Walz- und Rekristallisationstextur des Nickeleisens). W. G. Burgers & J. L. Snoek. *Zeitschrift für Metallkunde*, Vol. 27, July 1935, pages 158-60. The (200) pole figure was determined for a 50% Fe-Ni sheet reduced from 0.35 mm. to 0.1 mm. by cold rolling and found to be in agreement with the findings for other face-centered-cubic metals. It is best described as a scattering about all orientations for which a {135} plan is parallel to the plane of rolling, with a [335] direction in the direction of rolling. After recrystallization in H_2 at 1100° a preferred orientation was found with a {100} plane in the surface of the sheet and a [100] direction in the direction of rolling, with not more than 10° of scatter. The same textures were found for a 35% Ni alloy and were not altered by 2.5% Cu, but completely destroyed by small amounts of Co or Al. It is suggested that the differences in recrystallization texture found among face-centered-cubic metals can be explained by differences in fragmentation processes which occur along slip planes during deformation. Anisotropy of magnetization was observed in the recrystallized foil and found to be in agreement with previous work, magnetic susceptibility being least in the [100] direction. GD (10)

Microscope as an Indispensable Tool in Metal Industry, Especially in Foundries (Das Metallmikroskop als unentbehrliches Hilfsmittel in der Metallindustrie, insbesondere in Giessereibetrieben). H. Reininger. *Metallwaren Industrie & Galvano Technik*, Vol. 33, Sept. 15, 1935, pages 389-393; Oct. 1, 1935, pages 411-417. Discussion of usefulness of metallographic investigations which emphasizes the usefulness of the microscope to the foundryman. EF (10)

The Crystal Structure of γ-Fe_2O_3 and γ-Al_2O_3. E. J. W. Verwey. *Zeitschrift für Kristallographie*, Vol. 91, July 1935, pages 65-69. In English. The cubic spinel structure of γ Al_2O_3 and γ Fe_2O_3 is described as an averaged structure with regard to the cations. The oxygen arrangement is the same as in normal spinels. The unit cell contains 32 O ions, 21⅓ cations and 2⅔ vacant positions are distributed statistically over the 24 (8 + 16) cation positions of the spinels. EF (10)

Endurance Tests on Supersaturated Magnesium Solid Solutions (Dauerstandversuche an übersättigten Magnesium-Mischkristallen) W. Schmidt & H. Vosskühler. *Zeitschrift für Metallkunde*, Vol. 27, Aug. 1935, pages 179-182. With discussion. Plastic deformation of crystalline material, as in creep, is interpreted as due to interchange of atomic positions rather than shear. It was studied in a Mg alloy containing 8% Al, 0.5% Zn, and 0.2% Mn, which exists as a solid solution above 350° C., but retains only 3% Al at 140°. Tensile strength and creep are determined at 20° and 140° for the alloy in the as-cast condition, after forging, and after forging and homogenizing at 420°. For the latter 2 materials at 20°, both properties are of the same magnitude and very much greater than for the cast sample; at 140° the tensile-strength relations are similar, but the creep in the forged material is appreciably greater than that of the annealed. The creep curve of the homogenized material shows an exceptionally steep section which is shown by hardness and tensile tests and photomicrographs to be due to precipitation. This enhanced creep due to precipitation is also found in homogenized cast alloys and is absent if the homogenization is followed by a low-temperature anneal. GD (10)

Alloys of Lithium with Mercury and (with) Indium (Die Legierungen des Lithiums mit Quecksilber und Indium). G. Grube & W. Wolf. *Zeitschrift für Elektrochemie*, Vol. 41, Sept. 1935, pages 675-681. Heating and cooling curves were made of 67 Li-Hg alloys. The Li-Hg system as constructed from these data is briefly as follows: (composition is in weight % Li). 0-0.6, Hg; 0.6-18.0, $LiHg_3$; 18.0-29.0, $LiHg_2$; 29.0-70.0, solid solutions of LiHg; 70.0-72.0, Li_2Hg; 72.0-91.0, Li_3Hg; 91.0-92.0, Li_6Hg; 92.0-100.0, solid solutions of Li. One eutectic lies at 0.6% Li and —42° C. and another at 92% Li and 160° C. Li_3Hg and LiHg (375° C. and 590° C. respectively) melt without decomposition. The upper limits of the other compounds formed peritectically are: Li_6Hg, 164° C.; Li_2Hg, 375° C.; $LiHg_2$, 340° C.; and $LiHg_3$, 235° C. In the Li-In system only one compound, LiIn, exists; it melts without decomposition at 625° C. LiIn forms with Li a continuous series of solid solutions while with In it forms only a limited solid solution. The system between 0 and 10% Li requires more work for clarification. The compounds of these systems fit into the generalization regarding alkali metal compounds of Biltz and Zintl and their co-workers. HAS (10)

Solid-solution Series $MgCu_2$-MgNiZn and $MgZn_2$-MgCuAl (Die Mischkristallreihen $MgCu_2$-MgNiZn und $MgZn_2$-MgCuAl) Werner Döring. *Metallwirtschaft*, Vol. 14, Nov. 15, 1935, pages 918-919. As $MgCu_2$ and MgNiZn are both cubic, and $MgZn_2$ and MgCuAl are both hexagonal, a series of alloys in steps of 10% were made of these groups to determine whether they formed continuous solid solutions. The alloys were melted and homogenized, and their lattice constants determined by X-rays. In both cases solid solutions were found. In the $MgCu_2$-MgNiZn series the lattice constants remain the same, while in the $MgZn_2$-MgCuAl series a continuous decrease takes place. CEM (10)

Metallography, Report of Committee E-4. C. H. Davis, Chairman. *Proceedings American Society for Testing Materials*, Vol. 35, Part I, 1935, pages 511-512. Progress report. Subcommittee I on Selection and Preparation of Samples (E. H. Dix, Jr., Chairman) has prepared an extensive revision of the Standard Methods of Metallographic Testing of Iron and Steel (E 3-24) and the Standard Methods of Metallographic Testing of Non-Ferrous Metals and Alloys (E-5-27) which is recommended for publication as Tentative. **Proposed Tentative Recommended Practice for Metallographic Testing of Ferrous and Non-Ferrous Metals.** Pages 1319-1351. The preparation, etching and examination of the following metals and their alloys are summarized from a review of 94 references: Fe, Al, Cu, Pb, Mg, Ni, precious metals, Sn, and Zn. VVK (10)

Thermomagnetic Analysis of Metallurgical Products and Its Recent Applications (L'analyse thermomagnétique des products sidèrurgiques et ses récentes applications) P. Chevenard. *Métaux*, Vol. 10, Aug. 1935, pages 194-208. A recording thermomagnetometer is described and results on various magnetic materials are discussed. GTM (10)

Intercrystalline Failure of Metals. J. C. Chaston. *Metal Treatment*, Vol. 1, Winter 1935, pages 186-190. Reviews intercrystalline fractures in metals and alloys caused by (*1*) segregation of a weak constituent at the boundaries (*2*) parting of boundaries at temperatures just below melting (*3*) creep failure at boundaries of strengthened crystals at temperatures in the recrystallization range (*4*) selective corrosion of boundary material (*5*) intercrystalline corrosion by specific agents acting only when metal is stressed (*6*) obscure mechanism possibly involving stress concentration at the crystal boundaries. At high temperatures the probable reason why creep failures are not normally intercrystalline is that the boundaries are fugitive on account of the recrystallisation which follows the application of stress gradients. 24 references. JCC (10)

The Twinning of Single Crystals of Tin. Bruce Chalmers. *Proceedings Physical Society*, Vol. 47, July 1935, pages 733-746; *Technical Publications of the International Tin Research and Development Council*, Series A, No. 20, 1935, 13 pages. Includes discussion. Single crystals of Chempur tin were grown (usually with the 001 axis normal to the axis of the specimen) in glass tubes 0.5 to 1.0 cm. in diameter by the Bridgman method, and their orientation determined by observing light reflections from the surface after etching in 5% $FeCl_2$. Twinning could be readily brought about on the 301 plane by impact, the twinned portion turning through about 5°. By applying tension, a twinned specimen sometimes reverted to its original orientation with an audible click. By striking a suspended specimen with a ballistic pendulum, the energy given out on twinning was determined to be 8×10^5 ergs per $cm.^3$ of crystal twinned. JCC (10)

Recrystallization of Cast Aluminum (Rekristallisation von Aluminium im Gusszustand) H. Röhrig. *Zeitschrift für Metallkunde,* Vol. 27, Aug. 1935, pages 175-9. With discussion. Al containing 0.02% Fe, 0.017% Si, and 0.003% Ti, and a purer sample containing 0.003% Fe and 0.002% Si, as well as an alloy of the latter with 2% Cu all showed normal radial cast structures, both when cooled from 730° to 630° over a 5-hour period and when cooled from the casting temperature to 20° in 30 seconds. When annealed at 580° for 20 hrs. these showed recrystallization, and further annealing at 610° for 20 hrs. developed very large grains. This recrystallization does not occur if the anneal has not been preceded by cooling to room temperature. Alloys with 0.002% Si + 0.15% Fe, 0.07% Si + 0.11% Fe, and 0.19% Si + 0.42% Fe showed no such recrystallization and grain growth. From this it is concluded that additions which are not in solid solution at the annealing temperatures prevent recrystallization. A sharp contrast is shown between the scalloped grain boundaries of the cast structures and the straight boundaries in recrystallized material. GD (10)

A New Dilatometer for Elevated Temperatures (En ny dilatometer för höga temperaturer) S. Pyk, B. Stalhane & T. Westberg. *Jernkontorets Annaler,* Vol. 11, Oct. 1935, pages 401-411. The instrument consists of a quartz tube, heated electrically, in which the expansion of the test piece is measured by a dial registering 0.01 mm. differences in length. HCD (10)

Influence of Lattice Distortion on Diffusion in Metals. V. G. Mooradian & John T. Norton. *Transactions American Institute of Mining & Metallurgical Engineers,* Vol. 117, 1935, pages 89-101. Includes discussion. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 26L/5. (10)

Density Changes in Solid Aluminum Alloys. L. W. Kempf & H. L. Hopkins. *Metals Technology,* Jan. 1936, *American Institute Mining & Metallurgical Engineers Technical Publication* No. 671, 16 pages. The growth of a number of Al alloys in the range 175° to 230° C. following rapid cooling from a solution heat treatment was determined. Growth was determined by micrometer measurements. In obtaining growth with time, alloys were cooled from the elevated temperature, measured, and again heated. Growth varied from nil to 0.16%, depending on composition and heat treatment. Rate of growth under isothermal conditions varies over a relative wide range with variations in composition. At a specific temperature of heating, maximum mechanical properties and maximum growth occur at different periods of time at temperature, the attainment of maximum growth requiring considerably larger periods of time than maximum hardness. Growth at room temperature was too small to be measured. 8 references. JLG (10)

Surface Magnetization and Block Structure of Ferrite. W. C. Elmore & L. W. McKeehan. *Metals Technology, American Institute Mining & Metallurgical Engineers Technical Publication* No. 656, Dec. 1935, 15 pages. Surface magnetization of polished ferrite crystals with or without Si was investigated, using the magnetic powder method. Powder technique was improved by using a true colloid of γ Fe_2O_3 in water. The mazelike patterns and the changes in these patterns brought about by suitably changing the magnetizing field led to the proposal of a block model of cubes spontaneously magnetized along <100> or <110> axes. A study of patterns on various cuts of the same crystal gave additional evidence for this structure. The size of the cubes was found to vary from 0.5 to 3 μ, depending on the particular crystal. The stability of the secondary magnetic structure with respect to the polishing procedure adopted and to magnetic history was shown. It is suggested that the segregation of foreign atoms may account for the observed stability of the block boundaries. JLG (10)

Quenching Stresses and Precipitation Reaction in Aluminum-magnesium Alloys. R. M. Brick, Arthur Phillips & A. J. Smith. *Transactions American Institute of Mining & Metallurgical Engineers,* Vol. 117, 1935, pages 102-118. Includes discussion. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 26R/3. (10)

Alloys of Magnesium. III. Constitution of the Magnesium-rich Alloys Containing Aluminium and Cadmium. J. L. Haughton & R. J. M. Payne. *Journal Institute of Metals,* Vol. 57, No. 2, 1935, pages 287-296; *Metal Industry,* London, Vol. 47, Sept. 13, 1935, page 273. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 28L/8. Contraction of Aluminum and Its Alloys on Solidification. II. (Contrazione dell'alluminio e sue leghe all'atto della solidificazione. II.) L. Losana. *Alluminio,* Vol. 4, Nov.-Dec. 1935, pages 325-330. Pure Al contracts 6.36% on solidification. Occluded gases reduce this value slightly; thus a 100 g. sample containing 9.4 cc. O_2 and 3 cc. N_2 was found to contract 6.2%. Contraction of Al-Si alloys ranges from 5.82% for 0.42% Si to 2% for 15.17% Si. Occluded gases lower these results about 2%, i.e. from 2.00 to 1.98%. Al-Fe alloys containing 0.52-7.01% Fe, together with 0.03-0.19% Si show contractions of from 6.14-5.04%. With occluded O_2, these results are lowered to 5.72-4.18%, while with occluded water vapor they are 5.32-3.82%. The presence of Fe favors occlusion of gases. Al-Cu alloys ranging from 95.14% Al-balance Cu down to those containing 96.84% Cu-balance Al, show little variation, the alloy containing 4.86% Cu contracting 4.34%, that containing 94.12% Cu contracts 3.19%, the minimum. X-ray Examination of Fine Structure and Its Value for Surface Refinement (Die röntgenographische Feinstrukturuntersuchung und ihr Wert für die Oberflächenveredlung) A. Kufferath. *Oberflächentechnik,* Vol. 2, Jan. 21, 1936, pages 15-17. Principle and methods for applying homogeneous X-rays for the determination of structure, deformation, and recrystallization phenomena in metals, vitreous and ceramic materials, and wood are explained. 6 references. Ha (10)

Use of Coloring Reagents for Observations of Constituents in Carbon Steels Under the Microscope (Sur l'Emploi de Réactifs Colorants Destinés à l'Observation Microscopiques des Aciers du Carbone) Joseph Malette. *Comptes Rendus,* Vol. 201, Dec. 23, 1935, pages 1385-1387. Etchants for steel are suggested as follows: 15 g. ammonium molybdate is dissolved in distilled H_2O, added to 100 cc. HNO_3 (1.20 sp. gr.) and filtered after 4 days. 2 cc. of this solution is added to 100 cc. ethyl alcohol (95%) and the polished steel sample immersed. 2 other chemicals used were 15 g. ammonium vanadate or 15 g. ammonium uranate added to HNO_3 and ethyl alcohol as outlined above. FHC (10)

Modification of Aluminium-Silicon Alloys. II. U. A. Klachko. *Zhurnal Obshey Khimii,* Vol. 5, 1935, pages 1299-1301. Si in solid solution was determined in untreated and modified Al-Si alloys. The untreated silumin has 0.41% Si in solid solution; the slightly modified, 0.34%; modified, 0.20%; and highly modified 0.57% respectively. Modified silumin has as little Si in solid solution as the untreated. This confirms the theory of stabilization of the ultra-microscopical particles of Si by Na. NA (10)

The Constitution and Properties of Cadmium-tin Alloys. D. Hanson & W. T. Pell-Walpole. *Journal Institute of Metals,* Vol. 56, No. 1, 1935, pages 165-189. Includes discussion. See *Metals & Alloys,* Vol. 6, May 1935, page MA 203L/6. (10)

Transformation Twinning of Alpha Iron. Alden B. Greninger. *Metals Technology,* Feb. 1936, *American Institute Mining & Metallurgical Engineers Technical Publication* No. 689, 12 pages. An X-ray and optical study of the orientation relationship and habits of transformation twins in pure α Fe was made. Any one α grain may contain twin bands, contain smaller twin grains, or have a twin relationship to one or more of its neighboring grains. The habits of transformation twins are affected by varying the speed of cooling through A_3, mainly in the tendency of banding to disappear with very slow cooling. From a brief study of annealing twins it was concluded that such twins are only a minor structural constituent of annealed α Fe. The mechanisms that have been proposed to explain the $\gamma \rightarrow \alpha$ transformation in Fe would produce twinned structures, but do not account for the relationships between transformation twins found. Fe cooled through the transformation temperature was found to have a pronounced macromosaic structure, but Fe cold worked and then recrystallized in the α range did not. 14 references. JLG (10)

Sub-boundaries in a Crystal Grown by the Bridgman Method. W. H. George. *Nature,* Vol. 136, Sept. 7, 1935, page 392. A Cu single crystal showed some subboundaries or veining as has previously been seen in polycrystalline metals. CSB (10)

Extra Rings in Electron Diffraction Patterns. G. I. Finch & A. G. Quarrell. *Nature,* Vol. 136, Nov. 2, 1935, page 721. Presence of layer of grease on metal specimens gives rise to "extra" rings in electron diffraction; these rings are independent of nature of metal substrate. Other "extra" rings result from heating metals in a gas, and depend on nature of metal and gas; they are ascribed to absorbed gas. Still others are produced by amalgamation and vary with the metal amalgamated. Therefore caution is necessary in interpretation of "extra" rings. CSB (10)

Concerning Hardenable Bronzes with a Cu-Ni-Sn Base. VI. Addition of Cold Work Hardening and Precipitation Hardening (Über aushärtbare Bronzen auf Kupfer-Nickel-Zinn-Basis. VI. Addition von Kalthärtung und Ausscheidungshärtung) Erich Fetz. *Zeitschrift für Physik,* Vol. 97, Nov. 25, 1935, pages 690-698. Curves are given to show the increase in hardness versus the period of time with 2 alloys, one of 3% Ni, 8% Sn, remainder Cu and the other 2.5% Ni, 10% Sn, remainder Cu when the alloys are held at different temperatures. Cold working and precipitation hardening increase the strength of the alloy independently of each other regardless of the sequence of the 2 operations. FHC (10)

Recrystallization Accompanying an Allotropic Change. C. F. Elam. *Nature,* Vol. 136, Dec. 7, 1935, page 917. Recrystallization at an allotropic change point, similar to that occurring on heating a cold-worked metal, can be seen in NH_4NO_3, KNO_3 or $AgNO_3$ on a microscope slide, viewed with crossed Nichol prisms. Nuclei occur first at crystal boundaries or at an inclusion or blow hole. A cover slip pressed down on the fused salt slows down the recrystallization process conveniently. CSB (10)

Tests to Insure Tube Quality. Harry F. Dart. *Electronics,* Vol. 9, Feb. 1936, pages 32-33. Filaments of electron tubes are subjected to metallographic examination to insure proper functioning and long life. Large, elongated grains are desired. They are obtained by special heat treatment. Methods are briefly described. DJM (10)

The ϵ, γ and β Phases of the System Cadmium-Silver. P. J. Durrant. *Journal Institute of Metals,* Vol. 56, No. 1, 1935, pages 155-164. See *Metals & Alloys,* Vol. 6, May 1935, page MA 205L/3. (10)

Isotopic Constitution of Uranium. A. J. Dempster. *Nature,* Vol. 136, Aug. 3, 1935, page 180. Spectroscopic evidence is found for actino-U, an isotope of U of atomic weight 235. This is probably the parent of the actinium series of radioactive elements. There is about 0.4% as much of it on the earth as there is U. CSB (10)

Isotopic Structure of Iridium. A. J. Dempster. *Nature,* Vol. 136, Dec. 7, 1935, page 909. Confirms existence of 2 Ir isotopes of mass numbers 191 and 193, and 5 Pt isotopes. CSB (10)

Iron-carbon-silicon Diagram (Le Diagramme Fer-Carbure-Silicium) A. Dawans. *Revue Universelle des Mines,* Vol. 11, Dec. 1935, pages 541-552. Binary diagrams Fe-C, Fe-Si, and Si-C are explained and from them the ternary diagram Fe-C-Si is derived and discussed from the point of view of the practical foundry and steel worker. 12 references. Ha (10)

Variation in the Lattice Constant of Zinc Oxide. V. E. Cosslett. *Nature,* Vol. 136, Dec. 21, 1935, page 989. Zn oxide skimmed from molten Zn is unsuitable for a reference substance in electron diffraction studies since it is found to change its lattice constants appreciably in a few months. CSB (10)

Metallography of Steel (Metalografia del acero) J. Castells Ruiz. Jose Bosch, Barcelona, Spain, 1933. Fabrikoid, 6 x 8½ inches, 667 pages. Price 30 Psts.

The author is the head of the metallographic laboratory of a Spanish firm making aviation motors, and is also professor in the trade school of Barcelona. Beside this experience, he has worked in Continental steel plants and studied at Freiberg. The scientific and industrial background of the author allows him to deal with his subject in a practical way and from the engineering viewpoint. The subject matter covered is that normal to such treatises, but the relation of theory to practice, especially in connection with defects that need to be avoided in aviation material, is brought out more clearly than in the average treatise. The book is nicely printed and well bound. Reproductions of micrographs are especially well done.

Steel making is briefly discussed, solidification, working and heat treatment quite clearly dealt with, and alloy steels considered at some length. The final chapters deal with carburizing and nitriding. Ruiz gives considerable attention to the claims of Mahoux of Paris to the effect that high-frequency electric impulses during the nitriding process hasten the process and improve the product, and appears to be satisfied that the claims are justified, though he seems to be echoing the inventor's ideas rather than speaking from first-hand knowledge. In most other respects the information is confined to well accepted facts. Now and then a practice slightly antiquated from the U. S. point of view, is cited as normal, but on the whole, the Spanish practice, as reflected in the book, is quite up to date.

The volume is a decidedly good elementary treatise which should be very well received by metallurgists of the Spanish-speaking countries.

H. W. Gillett (10) -B-

The Structure of Metals and Alloys. W. Hume-Rothery. Monograph and Report Series, No. 1. Institute of Metals, London, 1936. Limp cloth, 5½ x 8½ inches, 120 pages. Price 3s. 6d.

This is a sort of correlated abstract, which attempts to show what the accumulated work of the last 15 years in crystal structure of metals and alloys allows one to conclude in terms of fundamental principles, which might permit some degree of prediction of behavior. About 300 references are given.

Starting with electron arrangement, crystallographic structure and atomic radii of the elements, the reader is led through solid solutions, the electronegative valency effect, relative valency effect, favorable size factor, etc., into forms of liquids and solid solubility curves, then to super lattices and intermediate phases and finally to imperfections in crystals.

The idea has long persisted that if we knew enough about the similarities and differences in the atomic make-up of metals, much of the information about any alloy system could be calculated from a few fundamental constants. We are still a long way from doing so, yet by relating the behaviors of different systems back to the electron configuration, atom size etc., by which coefficients of equivalents may be calculated, a rather plausible case may be made out to show that an alloy system is not a law into itself, but instead follows a pattern laid down for it in the properties of the elements. Whenever a general law is sought, plenty of exceptions and unexplained instances crop up, and many more years of accumulation of facts and attempts at their interpretation must ensue before a book of this sort can be classed as directly useful in the industrial laboratory, if, indeed, that time ever arrives. The groping for fundamental laws is, however, being done somewhat less blindly and with more hope of finding something that will remain reasonable when still more facts are brought forward, than was the case in many of the earlier discussions of the general topic.

The book is not easy reading, but is more readable, more interesting and more informative than most of its type. The author does not give the impression that he thinks that many of his attempts at correlation and explanation will hold water very long, he merely presents matters as he sees them at the moment. Whether the topic ever can be made really clear is a question, but the author has made a gallant attempt at clarification of a most complex subject.

Etching Methods for Micrographic Studies of Nickel and Monel Metal. D. E. Ackerman & R. H. Schaefer. *Inco*, Vol. 13, No. 3, 1935-36, pages 24-25. A reliable and rapid method is described for showing the microstructural features of Ni and Monel metal. Ha (10)

The Interpretation of the Equilibrium Diagram. N. P. Allen. *Proceedings Staffordshire Iron & Steel Institute*, Vol. 50, Session 1934-35, pages 98-119. A general discussion of simple equilibrium diagrams, and connection between atomic structure and mechanical properties, constituents of alloys, complex alloys, ordered and disordered states. GTM (10)

Oxidation of a Crystal Surface Studied by Means of Cathode Ray Reflection. Tasaburô Yamaguti. *Proceedings Physico-Mathematical Society of Japan*, Vol. 17, Series III, Nov. 1935, pages 443-454. In English. Effects of oxidation and of etching of cleavage surfaces of Zn blende on the reflection of cathode rays were investigated. Diffraction patterns proved that the oxidized product ZnO of Zn blende was a single crystal being so oriented that the (103) plane of ZnO was resting on the cleaved surface (110) of ZnS and that the [010] axis of the former is found to be parallel to the $[1\bar{1}0]$ axis of the latter. By taking into consideration the temperature effect in Waller's sense, a new interpretation is given of the formation of N-patterns. WH (10)

Cinematographic Record of the $\alpha \rightleftarrows \gamma$ Iron Transformation as Seen by the Electron Microscope. W. G. Burgers & J. J. A. Ploos Van Amstel. *Nature*, Vol. 136, Nov. 2, 1935, page 721. Using an electron microscope with one magnetic lens the microstructure of Fe was visible on the fluorescent screen even below 900° C. Surface of Fe was activated by evaporated Ba or Sr oxide. Image was photographed every 4 sec., giving cinematographic record. Grains of α Fe were seen to grow gradually into those of γ Fe when temperature was lowered slowly through transition point, thus differing from formation of martensite out of austenite, which is known to be sudden. CSB (10)

An X-ray Examination of Atomic Vibrations in Zinc and Cadmium. G. W. Brindley. *Nature*, Vol. 137, Feb. 22, 1936, page 316. X-ray scattering factors measured with Cu Kα radiation for Zn and Cd are a function of the orientation of the reflecting planes with respect to the c axis. This effect is too large to be attributed to assymmetry of atoms, but may be explained in terms of a greater thermal vibration of atoms along the c axis than normal to it, which is in accord with Grüneisen and Goen's theory of thermal expansion for these metals. CSB (10)

The Modification of Carpenter and Elam's Method of Producing Single Crystals of Aluminium by Deformation and Annealing. Vaughan H. Stott. *Transactions Faraday Society*, Vol. 31, Aug. 1935, pages 998-1000. Method of rolling Al is of great importance. Slight differences in the rolling can be eliminated by stretching the specimen 10%, and even 15%, after the first anneal of 6 hours at 550° C. and repeating the annealing. For the last annealing the temperature is raised at the rate of 10° C. per day, from 450° C. to 640° C., and then maintained at a temperature of 640° C. to 645° C. for a few days. 6 specimens are usually annealed together and not less than 4 crystals are obtained, 7″ long and ¾″ diam. An extension of 1.7% before the last anneal is necessary. This is probably close to the optimum value. To drill a 1/16″ hole, the crystal is carefully bored with a very sharp drill and annealed at a temperature rising slowly to 614° C. Etching will then show if the specimen is satisfactory. PRK (10)

New Technique for Obtaining X-ray Powder Patterns. R. A. Stephen & R. J. Barnes. *Nature*, Vol. 136, Nov. 16, 1935, page 793. New method for producing X-ray diffraction pattern of surface of metallographic specimen, giving sharp diffraction lines. A slit is placed between specimen and film, is oscillated with specimen, and transmits the diffracted beams only when they make a small angle with specimen surface. CSB (10)

The Deformation Lines in Alpha Brass. Carl H. Samans. *Journal Institute of Metals*, Vol. 55, No. 2, 1934, pages 209-213. See *Metals & Alloys*, Vol. 5, Dec. 1934, page MA 581. (10)

Specific Heats of Iron Nitrides. Shun-ichi Satoh. *Scientific Papers Institute of Physical & Chemical Research, Tokyo*, Vol. 28, Dec. 1935, pages 135-139. In English. A series of Fe-N alloys was prepared from Fe oxide by dissociation of Fe oxalate and reducing with H. NH_3 was passed over for 100 hours at 450° C. The mean specific heat of the alloys was determined between 0° and 100° C. in an ice calorimeter provided with evacuated walls. From the curve showing the relation between the specific heats and N content, the specific heats of Fe_4N and Fe_2N were derived. The former is 0.1242 and the latter 0.1343. The specific heats of the alloys increase linearly up to 5.9% N, (Fe_4N) the alloys consisting of α and γ' as is shown by Lehrer's diagram (*Zeitschrift für Elektrochemie*, Vol. 36, 1930, page 388). As the N content increases further, the slope of the specific heat curve increases and at 9.7% N is a maximum. This is attributed to the increasing amount of Fe_4N held in solid solution in Fe_2N (ϵ' phase range). The transformation point of Fe_4N namely $\epsilon \rightarrow \epsilon'$, is raised by the addition of Fe_4N, i.e. the transformation point is lowered by the addition of N. The alloys containing more N than 10.3% have a transformation point below 0° C. WH (10)

Metals, Mattes, Slags and Dross from the Point of View of Modern Chemistry (Les Métaux, les Mattes, les Laitiers et les Scories du Point du Vue de la Chimie Moderne) Maurice Rey. *Revue Universelle des Mines*, Vol. 12, Jan. 1936, pages 11-20. An attempt is made to explain the phenomenon of fusion, and particularly that of solubility of molten substances in one another, by applying the modern chemical theories. Chemical compounds are divided into ionic, atomic, and metallic combinations. The ionic compound is exemplified by NaCl, the 2 ions attract each other electrostatically. The atomic compound can consist of a homopolar or atomic combination having independent molecules or those having chains or crystalline lattices like the diamond. The metallic combination is characterized by certain electrons which are removed from the ions but are not divided up between the other atoms and travel about in the whole crystal lattice. The various groups are due to the deformation of the ions which cannot be considered as entirely rigid and indeformable structures; intratomic forces and electrostatic forces act against each other and cause a deformation of the ions. The deformability of anions and cations is different and has been determined by measuring the refractive index of the metal compound; Grimm has established a series of increasing deformabilities: Fe, NO_3, SO_4, CO_3, Cl, Br, I, O, S, Se; a table shows a classification of binary compounds according to these groups indicating which kind of compound is formed and their mutual solubility. The theory is discussed at length, and the expectation expressed that some day it will be possible to predetermine by the atomic theories melting and boiling points and even the form of binary and eventually ternary diagrams. 6 references. Effect of Prolonged Superheating in the Mechanical, Microscopic, and Macroscopic Characteristics of an Aluminum Alloy With and Without Addition of Titanium (Studio sull'effetto di un surriscaldamento prolungato sulle caratteristiche meccaniche macroscopiche e microscopiche di una lega di alluminio in presenza od assenza di titanio) A. Vivanti & R. Guastalla. *Alluminio,* Vol. 4, Sept.-Oct. 1935, pages 271-297. Effect of superheating on an alloy containing Cu 10%, Si 1%, Fe 0.5%, and Al the remainder, as well as this same alloy plus 0.2% Ti, has been studied. The temperatures of pouring were 660° and 800° C., the material being held at these temperatures for 1 and 2 hours before pouring. Superheating does not produce any injurious effects, and it improves those poured at 800° C. In any case, addition of 0.2% Ti neutralizes all the effects of superheating.

Age-hardening of Magnesium-aluminum Alloys. A. M. Talbot & John T. Norton. *Metals Technology,* Feb. 1936, *American Institute Mining & Metallurgical Engineers Technical Publication,* No. 692, 13 pages. Alloys were made from high-purity metals and contained approximately 10% Al. The process of aging at different temperatures was followed by measurements of hardness, electric resistivity, dilatation and lattice parameter, and by microscopic observation. Results proved that age hardening was due to the precipitation of a second phase from a supersaturated solution. The precipitation takes place very unevenly and may go to completion in one region before a neighboring region has started. There was no abnormal behavior of the properties measured that indicated the presence of any sort of pre-precipitation hardening phenomenon. JLG (10)

Type Metal Alloys. Frances D. Weaver (Mrs. Harold Heywood). *Journal Institute of Metals,* Vol. 56, No. 1, 1935, pages 209-240. Includes discussion. See *Metals & Alloys,* Vol. 6, July 1935, page MA 295L/4. (10)

Concerning a Peculiar Phenomenon at Transformations which Occur Over a Range of Temperature (Ueber eine besondere Erscheinung bei Umwandlungen, die sich über ein Temperaturgebiet erstrecken) A. Schulze. *Zeitschrift für Metallkunde,* Vol. 27, Nov. 1935, pages 251-255; *Physikalische Zeitschrift,* Vol. 37, Jan. 15, 1936, pages 41-43. The work of the author and other investigators upon the thermal properties of AuCu, $AuCu_3$, Ni, Fe, β brass and Ni-Fe and Ni-Cu alloys is reviewed with the object of demonstrating the striking resemblance in the behavior of these properties at about the temperature of magnetic transformation, in the cases of the ferromagnetic metals, and of the superlattice transformations in the case of the Au-Cu alloys and β brass. The temperature coefficient of electric resistance was shown in each instance to experience a small but sharp increase at a temperature ranging from 50° to 160° C. below that of the transformation (AuCu 220° C., $AuCu_3$ 230° C., Ni 210° C., Fe 670° C., β brass 270° C., Ni-Fe (17%) 410° C., and Ni-Cu (10%) 175° C., the transformations occurring at AuCu 420° C., $AuCu_3$ 395° C., Ni 350° C., Fe 720° C., β brass 445° C., Ni-Fe (17%) 550° C. and Ni-Cu (10%) 285° C.) and then to rise to a sharp peak at or very slightly below the transformation temperature. Similarly the temperature coefficients of thermal expansion were found to suffer slight discontinuities at the above mentioned temperatures followed by pronounced increase at the transformation. No deductions were drawn from these observations, but it is clearly implied that the magnetic and superlattice transformations must be analogous. 13 references. EF + FNR (10)

Effect of Uranium on the Structure, Hardenability, and Resistance to Tempering of Unalloyed Steels (Einfluss des Urans auf die Gefügebeschaffenheit, Härtbarkeit und Anlassbestandigkeit von unlegierten Stählen) H. Bennek & C. G. Holzscheiter. *Archiv für das Eisenhüttenwesen,* Vol. 9, Oct. 1935, pages 193-200. Good recovery of U without appreciable segregation was obtained on adding low-C ferro-U in the ladle to well-deoxidized melts. High-C ferro-U does not do so well because of the difficulty with which it is dissolved. Steels up to 5% U were forgeable. Two U carbides were observed. The solubility of U in austenite was indicated. Care must be taken in quenching to avoid incipient fusion because of the eutectic formed at comparatively low temperatures, about 1100° C. The depth of hardening is increased by U, the susceptibility to coarse grain growth reduced. U is a carbide-former like Cr. U gave little increase in the strength of structural steels. Microscopic Study of Ancient Bronze and Copper. C. G. Fink & E. P. Polushkin. *Metals Technology,* Feb. 1936, *American Institute Mining & Metallurgical Engineers Technical Publication* No. 693, 28 pages; (abstract) *Iron Age,* Vol. 137, Feb. 27, 1936, pages 34-37, 106. Over 50 pieces of bronze and Cu, all over 1500 yr. old, were examined and 39 are described. The chief aim was to study effect of extremely long periods of corrosion on structure. Structural peculiarities of ancient bronze and Cu are attributable to crude methods of smelting and treating. The difference between old and modern metals is, however, not always pronounced. There are some samples of ancient metal objects that are almost free from the usual impurities and their structure is normal in every respect. There is no sign of change in or disintegration of the solid solutions or other components, except that due to corrosion; this applies even to specimens 5000 or 6000 yr. old. Microstructural features of initial corrosion and of patina rather than structure of metal give the most reliable proof of the ancient origin of the metal. Characteristic differences were found in the initial corrosion of the many specimens of widely different origin or location examined. According to variations in the selective action and in the path of corrosion, 6 typical cases or distinct types of corrosion were revealed. 92 references.

11. PROPERTIES OF METALS AND ALLOYS

Internal Stress in Steel Caused by Dissolved Hydrogen Gas. Kotarô Honda & Tokutarô Hirone. *Kinzoku no Kenkyu,* Vol. 13, Apr. 1936, pages 121-126. In Japanese. The internal stresses in metal caused by the evolution of dissolved diatomic gas into small fissures present in the metal block during cooling are calculated by the equation,

$$p = \frac{K^2}{4V'^2}\left\{\sqrt{1 + \frac{4K_e\sqrt{p_eV'}}{K^2}} - 1\right\}$$

where p is the pressure of hydrogen gas in fissures,
K, the solubility constant of hydrogen in steel,
V′, volume of fissure per 1 g. of steel,
K_e, at the m.p. of steel,
P_e, pressure of hydrogen gas at m.p. which is in equilibrium with the molten steel,

It is found that the amount of the stress increases with the fall of temperature reaching a maximum at 300°-100°, then diminishes linearly and vanishes at absolute zero. Bennek, Schenck and Müller's hydrogen theory on the generation of flakes in steel, which is based upon an erroneous assumption, is criticized. According to the authors' theory ways to prevent the occurrence of flakes are: (1) to decrease the amount of hydrogen dissolved, (2) to avoid the segregation of inclusions, (3) to finish the transformation of steel or Ni-Cr steel above 400° C.
KT (11)

Temperature Relation of Plasticity (Zur Temperaturabhängigkeit der Plastizität) H. Eckstein. *Zeitschrift für Kristallographie,* Vol. 92, Dec. 1935, pages 253-274. Experiments on low melting metal crystals showed that their plastic behavior depends but little on temperature and that at extremely low temperatures (1.2°K.) a marked degree of plasticity is still preserved. It was concluded that plasticity is not a result of thermal atom movements but that the fundamental underlying phenomenon is of a non-thermal ("athermisch") nature onto which thermal effects become superimposed with rising temperatures. The present paper intended to reveal whether or not high melting metals as for instance W, ion-crystals (NaCl) and amorphous matter exhibit the same behavior. The former 2 materials confirmed that plasticity of crystalline materials is actually largely independent of temperature. Bakelite however, showed considerable changes of initial plastic stresses of 16°-60° C. which is in agreement with the thermal theory of plasticity.

Copper and the Copper Alloy Metals. James T. Kemp. *Paper Trade Journal,* Vol. 102, Feb. 6, 1936, pages 35-43. Cu and its commercial alloys are described. The physical properties of Cu can be varied at will within the limits of severe cold working on one hand and soft annealing on the other. Other metals are added to Cu to make a series of ductile alloys, within definite limits of composition, all stronger than Cu, with variable properties, and capable of being hardened by cold work or softened by annealing. Brasses, bronzes, Al bronzes, Cupro-nickels and "nickel silvers," the Cu-Si types and others are produced in sheet, rod, wire, and other wrought forms. Be-Cu is a recent development which with appropriate heat treatment attains physical properties equal to those of heat-treated steels. Tensile properties of the various alloys discussed are presented in tabular form. Corrosion resistance of these alloys is discussed. Data are presented on rates of corrosion by SO_2, dilute H_2SO_4, salt spray, and actual sulphite mill exposure.

Plasticity and Practical Behavior of Cast Light Alloys with Reference to the Bending Test (Plasticita e pratico Comportamento delle Leghe leggere gettate in Relazione alla Prova di Flessione). L. Locati. *Industria Mecanica,* Vol. 17, Sept. 1935, pages 803-807; Oct. 1935, pages 892-898. It was investigated what part the plasticity of a material plays in parts which are stressed beyond their elastic limit, and if the bending test can give sufficient indication as to the later practical behavior of a cast light metal. The tests showed clearly that the plasticity of the material helps the stresses of unforseen origin to remain in limits below the danger point even if they exceed the normal value. The other mechanical properties, however, such as elongation, must not be overlooked in this connection. The bending test alone will not give sufficient indication of behavior under stress, it can only give a certain quality factor which must be considered together with ultimate strength, elastic limit, maximum deflection in bending. 12 references. OFHC
REG. U.S. PAT. OFF.

OXYGEN-FREE HIGH CONDUCTIVITY

A Superior Copper
for All Purposes

OFHC Copper conforms to the A.S.T.M. Specification for electrolytic copper wirebars, cakes, etc., B5-27 with regard to metal content and resistivity, and is free from cuprous oxide.

OFHC Copper is characterized by its freedom from casting defects and its bar-for-bar uniformity. Its freedom from oxygen results in great ductility and toughness as evidenced by its high reduction of area and resistance to impact.

OFHC Copper withstands more working in hard condition when tensile strength is greatest, making it especially suited for products subjected to severe fabricating or service conditions.

Copies of a schedule of weights and dimensions of **OFHC** wirebars, cakes and billets, and a booklet containing technical information will be gladly furnished upon request.

Modulus of Elasticity, Elastic Limit and Softening Limit of Light Alloys (Modulo d'Elasticitá, Limite Elastico e Limite di Suervamento Nelle Leghe Leggere) M. Prever. *Industria Meccanica,* Vol. 12, Dec. 1935, pages 1041-1047. Elastic properties of Al alloys after various heat treatments are tabulated. The yield point is defined as that load which produces a permanent elongation of 0.2% after 2 min. of action of each individual increment of load. The results show particularly that the modulus of elasticity varies with the load, and that the elastic limit and yield point are more useful than tensile strength. Ha (11a)

Amorphous Antimony. J. A. Prins. *Nature,* Vol. 136, Aug. 24, 1935, page 299. Sb distilled in high vacuum is amorphous like a supercooled liquid; it gives an electron diffraction pattern of broad bands. Heating at 120°-150° C. crystallizes the deposit, producing many sharp diffraction rings. If deposit is extremely thin, the crystallized grains are small giving slightly widened rings. Orientation of crystalline deposit is random (crystallization at room temperature gives preferred orientation: *Nature,* Vol. 131, 1933, page 760). Scratching or heating to 97° ± 2° C. causes explosive crystallization. Electrodeposits of explosive Sb are probably small particles of amorphous Sb surrounded by monomolecular films of the salt electrolysed. CSB (11a)

Non-ferrous Alloys Available for the Use of Industry. *Aluminium & the Non-Ferrous Review,* Vol. 1, Nov. 1935, pages 55-58; Dec. 1935, pages 87-88. Lists the composition and properties of the following: the Ce-Al alloys, Ceralumin B, C and D; the Al alloys, "L5," "L8," "Y" and Alpha, Beta and Gamma Alpax; Zn base, Mazak Nos. 2, 3, 5 and 6; the Mg Elektron alloys (11); and Sterling Metal alloys SM 82, SM 101 and SM 116. JCC (11a)

Tungum Alloy. *Aluminium & the Non-Ferrous Review,* Vol. 1, Dec. 1935, pages 115-116. The properties of tungum alloy (composition not given) are described, with notes on its casting, forging, joining, and machining. Good corrosion resistance, particularly to sea-water, is an important characteristic. Figures for loss of weight after immersion in a number of reagents are listed. Tensile strength varies from 20 tons/in.^{2} (cast) to 90 tons/in.^{2} (wire). JCC (11a)

Research on Thin Layers of Tin and Other Metals. (1) The Influence of Thin Metal Layers on the Deterioration of Technical Insulating Oils. P. J. Haringhuizen & D. A. Was. *Technical Publication of the International Tin Research & Development Council,* Series A, No. 29, 1936, 7 pages. Reprinted from *Proceedings Koninklyke Akademie van Wetenschappen te Amsterdam,* Vol. 38, 1935, pages 1002-1006. Deterioration of insulating oils in contact with Sn, Pb and Cu was studied by heating the oils at 90° C. in contact with glass alone and with glass coated with metal films obtained by high vacuum evaporation. Quantitative determinations of the sludge formation and change in color after 1000 hours showed Cu to give the greatest deterioration, Pb less and Sn the least. With 2 of the 3 oils deterioration was less with Sn present than with glass alone, indicating that Sn may act as an anti-oxidant. Tests made every 200 hours showed the increase of acidity of the oil to be greatest with Cu and least with Pb for the first 1000 hours. After about 1200 hours the acid value in presence of Pb rapidly exceeded that of the other metals, hence the ultimate increase in acidity was least in the presence of Sn. BWG (11a)

Elasticity Measurements on Aluminum at Elevated Temperature (Elastizitätsmessungen an Aluminium bei erhöhter temperatur) J. Verö. *Royal Hungarian Palatin-Joseph University of Technical & Economical Sciences, Faculty of Mining, Metallurgy & Forestry, Sopron,* Vol. 7, Part 1, 1935, pages 163-170. Method to determine elastic deformations is described which permits taking into account more exactly than is possible in the usual methods the permanent deformation caused by creep at higher temperatures. Tests made on Al up to 340° C. are described in full. The elasticity modulus decreased from about 6500 kg./mm.^{2} to about 3650 kg./mm.^{2} at 340°. Ha (11a)

Thermomagnetic Hysteresis in Nickel Wire. Y. K. Hsü & William Band. *Proceedings Physical Society,* Vol. 47, Sept. 1935, pages 910-922. The hysteresis effects exhibited by the thermomagnetic e.m.f. produced in a 1.0 mm. diam. Ni wire subjected to longitudinal magnetic fields and tensions under different conditions of temperature distribution are studied. JCC (11a)

Experiment on the Variation of the Alternating Current Resistance of Ni in a Longitudinal Magnetic Field (Untersuchung der Änderung des Wechselstromwiderstandes von Nickel im longitudinalen Magnetfelde) M. M. Sen Gupta, H. B Mohanti & S. Sharan. *Zeitschrift für Physik,* Vol. 98, Dec. 14, 1935, pages 262-266. Authors claim a close relation between the variation in the resistance and the magnetization of Ni placed in a longitudinal magnetic field. The results with a.c. differ from those with d.c. if the hysteresis is low and if no residual resistance appears. FHC (11a)

Magnetic Properties of Solutions of Cadmium in Molten Cadmium-Chloride and of Molten Calomel. J. Farquharson & E. Heymann. *Transactions Faraday Society,* Vol. 31, Aug. 1935, pages 1004-1010. Magnetic measurements using the Gouy method with solutions of Cd and molten $CdCl_2$ and with molten calomel were made. In no case did paramagnetism appear. Thus, a subchloride, CdCl is definitely excluded. The probability of either a subchloride, Cd_2Cl_2 or an atomic solution of Cd in $CdCl_2$, was discussed. A comparison of the magnetic properties with the electrical conductivity of molten calomel led to the assumption that it consisted of Hg_2Cl_2 molecules which were to some degree dissociated into Hg^+ and Cl^-. There is an unexpected large rise in diamagnetic susceptibility when $CdCl_2$, $PbCl_2$ and Hg_2Cl_2 melt. 23 references. PRK (11a)

Tantalum and Columbium, Produced by Special Methods, Have Many Uses. C. W. Balke. *Steel,* Vol. 97, Sept. 2, 1935, pages 50, 53. **Tantalum in Chemical Plant.** *Chemical Trade Journal & Chemical Engineer,* Vol. 97, Oct. 25, 1935, page 349. Measurements of the Thermal Expansion of Cast and Rolled Zinc. H. GOULBOURNE JONES. *Proceedings Physical Society,* Vol. 47, Nov. 1935, pages 1117-1128. When measurements of the thermal expansion of cast Zn are made with increasing temperatures, a sharp discontinuity is revealed at a temperature depending on the previous heat-treatment and the size of the Zn crystals. It is suggested that the growth of the crystals during the experiment influences the expansion. In rolled Zn, discontinuities were found to be associated with the long axes of the crystals most of which are oriented perpendicular to the plane of rolling. Continuous-cooling curves, on the other hand give reliable results. Expressing expansion by

$$L = L_0(1 + \alpha T + \beta T^2 + \gamma T^3 + \delta T^4)$$

the follow average values for the constants were found:—

	$\alpha \times 10^6$	$\beta \times 10^9$	$\gamma \times 10^{12}$	$\delta \times 10^5$
Cast Zn unannealed	27.84	—47.52	178	—18
Cast Zn annealed	29.65	10.84	—68.4	129

The Hardenable Bronzes of the Copper-Nickel-Tin Type. II. Wrought Alloys (Ueber aushärtbare Bronzen auf Kupfer-Nickel-Zinn-Basis. II. Knetlegierungen) E. FETZ. *Metallwirtschaft,* Vol. 15, Feb. 14, 1936, pages 167-170; Feb. 21, 1936, pages 189-191. Hardness-temperature curves are plotted for Cu and its alloys with 5 and 12% Sn, 15 and 20% Ni which have been reduced to ¼ their original thickness before annealing. The Sn alloys show greater hardness and lower recovery temperatures, but they cannot be worked as much. Cu-Ni-Sn alloys with 0-15% Ni + Sn are treated similarly and the hardening and capacity for reduction are shown to be additive properties. Rates of hardening at 250°, 300°, and 350° C. are determined for 2 Cu-Ni-Sn alloys which have been cast, forged, and cold rolled 25-75%. The rates increase in the order listed and the curves also show that hardening without recovery is possible below 300°. These rates show anomalous concentration and recovery effects which cannot be explained by the data from the binary alloys. Composition-hardness curves for alloys of Cu with Sn, Ni, and Sn + Ni show greater hardness for chill cast than sand cast specimens, the hardness being further reduced by annealing for all types. A direct proportionality between hardness and tensile strength is shown for all of the samples mentioned, whatever the pre-treatment. Elongation and proportional limits are also plotted, showing the great advantages obtained by addition of Ni in both the cast and treated condition. GD (11a)

Recent Advances in Zinc Metallurgy. WALLACE G. WOOLF. *Mining Congress Journal,* Vol. 22, Feb. 1936, pages 42-43. High-grade Zn (99.99%+) has been developed for die casting, which now takes about ⅛ of the quantity of Zn used in galvanizing, still the major outlet for this metal. Die cast Zn is used extensively in the automobile industry. Zn alloys having tensile strength of 44,000 lbs./in.², and impact strength of about 15 ft.-lb., are now used in die casting. Late developments have resulted in commercial electrolytic Zn with a purity of 99.9975%. High-grade Zn is also used in galvanizing for articles subject to extra severe bending stresses and where permanence and rust resistance are highly important, such as in telephone lines and in bridge construction. Steels and Alloys for Permanent Magnets (Les aciers et alliages pour aimants permanents) ANDRÉ MICHEL. *Revue de Métallurgie,* Vol. 32, Oct. 1935, pages 482-486. A review of the literature. When alloys are in solid solution, addition of a new phase increases hardnesses but does not affect coercivity. Outside of the solid solution range coercivity increases with the increase of the precipitated phase. There is no relation between hardness of an alloy and its magnetic properties. The size of the precipitated particles affects coercivity, best value being obtained with the critical size. Coercivity is affected by mechanical stresses. All contemporary magnet steels and alloys depend on the precipitation of a new phase. It might be a definite chemical compound or a new allotropic phase, as in Fe-Ni alloy proposed by Mishima. See also *Metals & Alloys,* Vol. 7, Apr. 1936, page MA 203R/7. JDG (11b)

Vanadium Steels (Die Vanadinstähle) HANS HOUGARDY. P. u. G. Gärtner, Berlin, 1934. Cloth, 6¼ x 9¼ inches, 224 pages. Price 8 RM.

In this little volume the reader will find a brief yet quite complete presentation of what is known of the characteristics and behavior of V steels, including not only the records to be found in the technical literature but also data taken from unpublished work of the author.

The contents are divided into 3 principal parts—the properties and manufacture of V and its alloys—the constitution and properties of V-Fe alloys—and the application of V in practical Fe and steel manufacture. In the first section V ores and minerals are discussed, along with the methods of preparation of pure metal and ferro-alloys, the treatment of the V-Ti iron ores, and the methods of alloying steels with V. The second section is entirely physical-metallurgical in character, discussing constitution and the influence of V on various properties of Fe. In the third section considerable attention is devoted to the simple and complex V steels and their mechanical properties, special consideration being given to Cr-V and Cr-Ni-V wrought steels, to carburizing and nitriding steels and to cast steels. A very complete treatment of tool steels follows and among other items, a record of the published data on V cast irons.

To the reviewer the last 2 of the principal parts of the book have received the best and most complete treatment. The first is not so close to perfection as for example in the statement that the roscoelite and carnotite ores are not of current importance and the omission of Marden and Rich's excellent work in the preparation of pure V by reduction with alkali metals. An excellent bibliography is included, and although the author's names in the English and American references are not very precise, this should prove no serious inconvenience if locations have been accurately recorded. In a book of this nature critical appraisal of published data is very beneficial and more of this would have been helpful.

Steel for Steel Castings. W. WEST. *Proceedings Institute of British Foundrymen,* Vol. 26, 1932-1933, pages 597-614. See *Metals & Alloys,* Vol. 4, Oct. 1933, page MA 335. CEJ (11b)

American Malleable Iron and Its Derivatives (Le malléable américaine et ses dérivés) RAYMOND GAILLY. *Revue de Métallurgie,* Vol. 33, Jan. 1936, pages 38-42. French Railroad specification No. 19 for malleable iron specifies only that it could be deformed under a hammer to show that it is malleable and that a punch might be driven through it as easily as through soft steel. Specification No. 53 calling for min. tensile strength of 35 kg./mm.² and min. elongation of 10% in 115 mm. is never used. Brief summary of the methods employed in making it and the changes produced by various additions taken from published data. JDG (11b)

Determining the Quality of Unalloyed Tool Steel (Güteprüfung von unlegierten Werkzeugstahl) E. HOUDREMONT, H. SCHRADER & A. CLASEN. *Archiv für das Eisenhüttenwesen,* Vol. 9, Sept. 1935, pages 131-146. The behavior of 1% C tool steels, made with different furnace practice, was tested after quenching, annealing, carburizing, and decarburizing. Repeated quenching was found unsuitable for determining the sensitivity to quenching cracks. Deep hardening steels showed up poorly in bend tests of hardened samples. The cementite network in carburizing tests at 1000° C. gave indications of the sensitivity to overheating. Steels melted with "pure" (carbonyl) Fe in the charge showed more pronounced coalescence of the cementite on heating below A_1. On decarburization in moist H_2 steels with "pure" Fe in the charge seemed to give more decarburization. The technical steels were all normal. Steels with "pure" Fe in the charge were abnormal, i.e., showed coalescence of the cementite in the carburized layer. It was concluded that an abnormal structure in the McQuaid-Ehn test is not due to dissolved O but to higher purity of the charge; this causes more rapid coalescence of the cementite because Ar_1 is higher so that the pearlitic cementite formed can coalesce more readily just beneath Ar_1. Iron for Relays and Electromagnets. A. S. ZAIMOVSKI. *Kachestvennaya Stal,* No. 9, 1935, pages 37-40. In Russian. Electrical properties of pure Fe are presented in the light of the contemporary literature but mostly based on Yensen and Ziegler's work. (11b)

The Kinetics of Sorption Processes of Hydrogen on Iron. N. M. MOROZOV. *Transactions Faraday Society,* Vol. 31, Apr. 1935, page 668. Three different types of sorption are shown to exist in the temperature range between —190° and +400° for the sorption of H by Fe. They are: van der Waals adsorption, activated adsorption, and activated diffusion. In certain temperature ranges it is possible to separate these processes and investigate the kinetics of each individual process. A value of $E \sim 20{,}000$ Cals. has been obtained for the activation energy of activated adsorption (for 1.0cc. of amount of gas adsorbed) and a value of $E \sim 8{,}000$ Cals. for activated diffusion. In the temperature range from 300° to 400° the activated adsorption is an instantaneous and entirely reversible sorption process. Howard's results showing that the activated adsorption diminishes the van der Waals' adsorption are confirmed. It is shown, however, that under certain experimental conditions the absence of such a relation between the 2 types of sorption is possible. 9 references. PRK (11b)

Special Cast Irons (Les fontes spéciales) Auguste Le Thomas & Marcel Ballay. *Revue de Métallurgie,* Vol. 33, Jan. 1936, pages 24-37; (abstract) *Journal du Four Electrique,* Vol. 45, Feb. 1936, page 60. A summary of the present knowledge of the subject based on published data. JDG (11b)

Nickel-Copper Structural Steels. *Nickel Bulletin,* Vol. 9, Feb. 1936, pages 29-33. The addition of Ni to structural Cu steels enables the producer to overcome the surface cracking of Cu steels (at least half as much Ni as Cu is required) and to obtain improved resistance to corrosion and superior mechanical properties. Composition and properties of a series of Ni-Cu, Ni-Cu-Cr and Ni-Cu-Mo steels are given in tables. Ha (11b)

Special White Cast Irons (Les Fontes Blanches Spéciales) M. Ballay & R. Chavy. *Bulletin de l'Association Technique de Fonderie,* Vol. 9, Nov. 1935, pages 366-380. French exchange paper presented at the International Foundry Congress, Brussels, Sept. 1935. An investigation of the physical properties of Ni-Cr white cast irons. Austenite-martensite structures were secured by use of alloy additions as low as Ni 3.0% and Cr 1.5%. Brinell hardness up to 800 was obtained. Same austenitic white cast irons were very resistant to acid corrosion. Among proposed uses of these materials were: (a) finishing rolls, (b) sand blast nozzles, (c) replacing tungsten carbide in certain uses, and (d) corrosion resistant equipment. WHS (11b)

Purchasing Data for Various Grades of Steel Castings. R. A. Bull. *Steel,* Vol. 98, Mar. 23, 1936, pages 36, 38, 40, 43. Summary of chemical composition and physical properties set down in all current A. S. T. M. specifications for steel castings, with explanatory text. MS (11b)

American Progress in the Use of Alloys in Cast Iron. F. B. Coyle. *Proceedings Institute of British Foundrymen,* Vol. 26, 1932-1933, pages 177-259. See *Metals & Alloys,* Vol. 5, May 1934, page MA 225. CEJ (11b)

Cast Iron and Steel Differentiated. A. L. Norbury. *Iron Age,* Vol. 136, Nov. 7, 1935, pages 25, 104, 106, 110, 112. See "On the Definition of the Terms 'Cast Iron' and 'Steel'," *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 141L/4. VSP (11b)

Role Played by Supplementary Elements When Added to Non-Oxidizing Steels (Role des Eléments d'Addition dans les Aciers Inoxydables) E. Pretet. *Chimie et Industrie,* Vol. 33, May 1935, pages 1061-1063. Supplementary elements added to stainless steels exercise various effects on chemical resistance of the steels. They modify the properties of the basic solid solution in which they themselves go into solution; they determine the nature and number of phases which can exist in the alloy; and they permit various heat treatments. They determine the nature of the non-metallic phases separated before and during solidification and which affect the quality of the metal. MAB (11b)

Tests of Low-Tungsten Molybdenum High Speed Steel (Versuche mit wolframarmem Molybdän-Schnellarbeitsstahl) H. Pohl. *Stahl und Eisen,* Vol. 55, Sept. 19, 1935, pages 1001-1005. Steels of about 4% Cr, 8% Mo, 2% W, and 1% V were compared with the usual 18% W, 4% Cr, 1% V composition. No difficulties in melting were encountered although greater care was necessary in heat treatment to avoid decarburization and volatilization of Mo. The best quenching temperature was at about 1200°-1220° C., considerably lower than the comparison W steel; the best tempering temperature was also lower; at about 540°-560° C. Drilling and turning tests indicated the life of both types of steel to be about equal, although in previous tests the Mo steel showed more fluctuation. SE (11b)

Impact Resistance and Other Physical Properties of Alloy Gray Cast Irons. Garnet P. Phillips. *Transactions American Foundrymen's Association,* Vol. 6, Dec. 1935, pages 125-141. To determine impact resistance of alloy cast irons, samples from 38 cupola heats and 20 electric furnace heats were tested. Alloy additions used were Cr, Mo, Ni, Cu, and Ti. In addition to impact test results, tests on other physical properties were made. 10 heats of the electric furnace irons were heat treated. The effects of the alloys on the physical properties are compared and discussed. Test results indicate that in the case of irons cast gray and omitting austenitic irons, fairly high C Ni-Mo irons that may contain some Cr, have good impact resisting properties. The highest impact resistance was obtained on irons cast white and converted to gray irons by annealing. Transverse resilience correlates fairly closely with impact resistance and single blow tests made on machined bars apparently correlate with transverse resilience more closely than does the repeated drop test on unmachined bars. Alloyed Grey Cast Iron. Carl W. Pfannenschmidt. *Proceedings Institute of British Foundrymen,* Vol. 26, 1932-1933, pages 104-138. See *Metals & Alloys,* Vol. 5, May 1934, page MA 222. CEJ (11b)

Rail Steel and Rail Wear. L. Sanderson. *Metallurgia,* Vol. 13, Feb. 1936, pages 113-114. Discusses properties of different English rail steels and concludes that basic bessemer rails are inferior to rails made by acid bessemer or acid open-hearth process. Analyses and tensile properties of some rails are given. JLG (11b)

Phosphorus in Cast Iron. W. West. *Proceedings Institute of British Foundrymen,* Vol. 26, 1932-1933, pages 392-417. See *Metals & Alloys,* Vol. 5, Apr. 1934, page MA 158. CEJ (11b)

Effect of a Graphite- and Silicon-Poor Pig Iron on the Mechanical Properties of Gray Iron at Elevated Temperatures (Ueber den Einfluss eines graphit- und siliziumarmen Roheisens auf die mechanischen Eigenschaften von Grauguss bei höheren Temperaturen) M. Paschke & Fr. Bischof. *Giesserei,* Vol. 22, Dec. 20, 1935, pages 625-627. Four series of melts with charges of different compositions of pig Fe were made and are described in detail. They show that with increasing addition of special pig Fe, tensile strength, impact-hardness and notch-toughness increase at elevated temperatures. Ha (11b)

Variations in Resiliency (Variaciones en el Valor de la Resiliencia) J. Castells Ruiz. *Metalurgia y Construccion Mecanica,* Vol. 1, Feb. 1936, page 7. Curves showing the change of resiliency with the temperature applied in heat treatment are reproduced for a low C steel (0.05% C) and for a Cr-Ni steel (0.25% C, 0.78% Cr, 2.75% Ni). Ha (11b)

Typical Applications and Advantages of Alloy Steels. N. M. Salkover. *Modern Machine Shop,* Vol. 8, Jan. 1936, pages 36-46. A general review of alloy steels now available, their SAE definitions and fields of applications, composition and price. Ha (11b)

The Chilled Car Wheel. F. K. Vial. *Official Proceedings, Canadian Railway Club,* Vol. 34, Nov. 1935, pages 24-135. Includes discussion. The most widely used of the 3 types of materials for railroad car wheels (chilled iron, forged steel and cast steel) is now chilled iron because its properties are more peculiarly adapted to this kind of service than any other material and the first and ultimate costs are very low. The composition is Fe with 3.4% C. In the chilled portion of the wheel C is all combined, whereas in the gray Fe part the combined C is 0.90% or less and the graphite 2.5% or more. After an exhaustive treatment of the development and description of numerous tests for cost, economy, breaking and brake shoe qualities, rail wear and shop costs, the metallurgical aspects are discussed and heat-treating furnaces for foundries and testing methods of hardness of the wheels described. The effect of heat-treatment on the chilled Fe is to change the familiar lamellar pearlite into spheroidized pearlite. Photographs of microstructures are reproduced. The advantages of the chilled Fe wheel are summarized as follows: extremely low cost as the worn wheel is taken in part payment for a new wheel, a guarantee of 4 years under 50-70 ton cars up to 6 years under 30 ton cars, 20% greater durability of brake shoes on this than any other type of wheel, minimum abrasion of rails, reduced train resistance and low shop costs. Ha (11b)

Plastic Strain and Creep Stress. R. W. Bailey. *Journal & Record of Transactions Junior Institution of Engineers,* Vol. 46, Oct. 1935, pages 1-29. See *Metals & Alloys,* Vol. 6, June 1935, page MA 249R/2. WH (11b)

Corrosion-resistant Steels. H. Bull. *Chemical Trade Journal & Chemical Engineer,* Vol. 97, Dec. 27, 1935, pages 549-550. See "Stainless Steels," *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 86L/2. MS (11b)

The Evolution and Progress of Rust-, Acid- and Heat-resisting Steels. W. H. Hatfield. *Iron & Coal Trades Review,* Vol. 132, Jan. 17, 1936, pages 134-136. Present status of corrosion and heat resisting steels, their fields of application, and further necessary developments are discussed. Ha (11b)

Length Variations of Steel Wire During Aging Following Severe Disturbance. H. Goulbourne Jones. *Metallurgia,* Vol. 13, Mar. 1936, pages 155-157. Wire samples of 0.22" diameter and 3" long from steel with 0.06% C and 0.48% Mn were used. Length changes were measured with an optical lever that indicated changes in length as small as one part in a million. Quenching, holding in an alternating magnetic field or stressing caused subsequent small changes in length on holding at room temperature. These changes lasted for as long as 7 days, but the total amplitude of change was less than 0.02%. JLG (11b)

Meehanite Metal Creates New Standards in Iron Castings. W. H. Kinney. *Industrial Gas,* Vol. 14, Feb. 1936, pages 17-19, 25. Meehanite cast Fe is a pearlitic cast Fe with the graphite uniformly distributed throughout the Fe, with the free C in the form of small nodules surrounded by a matrix of ferrite and pearlite. The process of making this type of Fe makes it possible to control the mechanical properties according to definite specifications. Charts show the comparative strength, hardness and growth of ordinary and Meehanite cast Fe after repeated heating. Ha (11b)

Effect of Copper on Cast Fe and Cast Steel (Einfluss des Kupfers in Eisen- und Stahlguss) *Die Metallbörse,* Vol. 25, Jan. 5, 1935, pages 17-18; Jan. 12, **1935, page 51. Physical properties of Fe** in relationship to Cu contents (0.1-8% Cu) are tabulated. Fe with 2% Cu can be easily forged at relatively low temperatures. The age-hardening results of Kinnear are presented in a table inter-relating heat treatment, Cu and C content and aging effect. The physical properties of a Cu bearing steel with 0.16% C, 1.06% Cu, 0.55% Mn and 0.34% Si in the annealed and age-hardened state at temperatures ranging from 20°-400° C. are compared with those of a 0.38% C, 0.65% Mn, 0.139% Si steel. EF (11b)

Composite Steels for Jail Use Must Meet Rigid Specifications. *Iron Age,* Vol. 137, Mar. 19, 1936, pages 43, 65. Primary specifications for jail steels are high resistance to sawing and breaking. Composite steels of two or more distinct types and analyses have been meeting the requirements. In the construction, the important feature is in arrangement of hard steel inserts which are covered with a steel of softer composition. The arrangements of inserts form what is known as "bird-cage" type specified by New York State and in general use. In forming the flooring and roofing the so-called "five ply" type is used, consisting of 3 plies of soft and 2 plies of hard steels. The analyses of steel produced by Jessop Co., represents a practical standard for meeting current rigid requirements: *Inserts:*—C 1.45-1.55%; Mn 8.00%; Si 0.30-0.35%; Cr 4.00-4.50%; S, and P a trace. *Soft steel:*—C 0.15% max.; Mn 0.50%; Si 0.25%; S 0.020% max.; P 0.020% max. VSP (11b)

Heat Resisting Steels. *Edgar Allen News,* Vol. 14, Apr. 1936, pages 825-826. The various steels made by the Edgar Allen Co., their mechanical properties and safe working loads up to 1100° C. are described. They comprise austenitic Ni-Cr steel, austenitic Ni-Cr-W steel, austenitic high Cr-Ni steel, high Cr steel, and other Ni-Cr steels. The best fields of employment for each type are described. Ha (11b)

12. EFFECT OF TEMPERATURE ON METALS AND ALLOYS

L. JORDAN, SECTION EDITOR

Long-Time Creep Tests of 18 Cr 8 Ni Steel and 0.35 Per Cent Carbon Steel. H. C. Cross & F. B. Dahle. *Transactions American Society of Mechanical Engineers,* Vol. 58, Feb. 1936, pages 91-96. Results are given on tests which have run for 7000 and 5400 hrs. respectively and are still being continued. Both specimens, after showing at first diminishing rates due to strain hardening on account of deformation, now show increasing rates of creep as the tests progress. The change occurred in both after about 3000 hrs. No prediction as to further behavior can be made from the curves so far taken with about 8000 lbs./in.^{2} The present deformation is now less than 0.0001%/hr. Ha (12)

High-Temperature Properties of Cast and Wrought Carbon Steels from Large Valves for High-Temperature Service. H. C. Cross & F. B. Dahle. *Transactions American Society of Mechanical Engineers,* Vol. 58. Feb. 1936, pages 103-113. Two forged and 2 cast C steels were compared with regard to structure and behavior at 750°, 850° and 950° C. under short-time tension tests and impact tests. The tensile properties at room temperature were quite similar for the samples with the same C content. The forged steels show the best Charpy impact tests at room as well as at the higher temperatures. A slightly lower value is shown by the cast steel with spheroidized structure while the ordinary C cast steel has the lowest impact resistance. The forged steels showed the best creep resistance at high temperatures, the cast steels were poorer. There appears no correlation between the results of the short-time tension and long-time creep tests at the elevated temperatures. No broad generalization of cast vs. wrought or coarse-grained vs. fine-grained steels is warranted by the results, as other factors such as soundness, strength, ductility enter into the choice of C steels for specific purposes. 19 references. Ha (12)

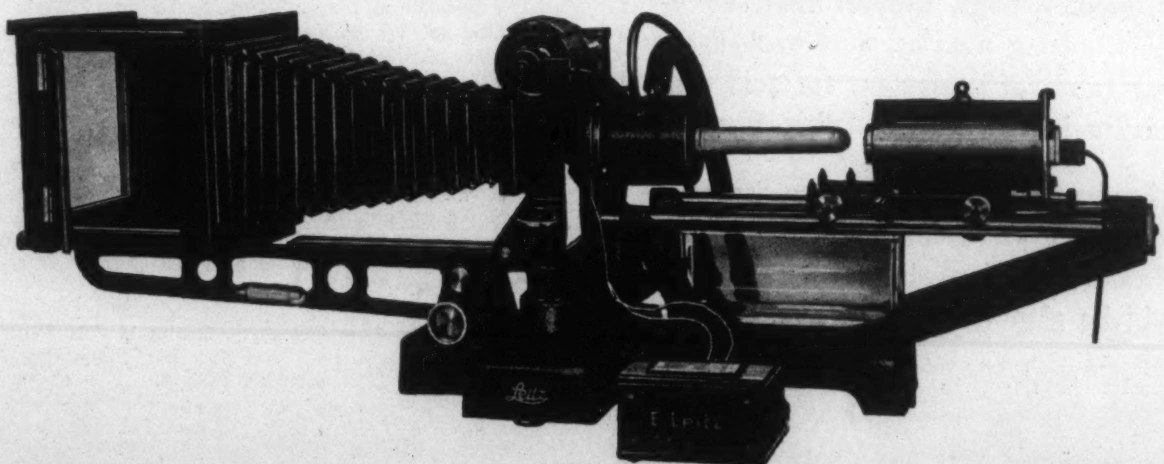
Plasticity and Fracture of Steels at High Temperature (Plasticité et Rupture à Chaud des Aciers) M. de Lacombe. *Chimie et Industrie,* Vol. 33, May 1935, pages 793-799. Modern surgery demands steels which are less like ordinary C steels and which contain higher percentages of such elements as Cr, Ni, W, Co, etc. The manufacture of such steels is rather difficult, and many steels are not resistant to heat and high temperatures. Article covers a study of the structure of special steels and the modifications to which they are subjected at various temperatures, reviews the various kinds of defects which arise, and suggests the manner of research to make the kind of structure which is most desirable for these purposes. MAB (12)

Creep Resistance of Welded Boiler Plates (Dauerstandsfestigkeit geschweisster Kesselbleche) C. Appaly. *Die Wärme,* Vol. 58, Sept. 28, 1935, pages 639-643. Creep tests at the Technische Hochschule, Breslau, proved that a boiler plate weld, which has not been annealed, has a higher creep resistance than either the plate itself (0.085% C, 0.017% P, 0.47% Mn, 0.036% S) or the filler rod (0.09% C, 0.015% P, 0.5% Mn, 0.02% S, trace Si) due to the setting-up of internal stresses and due to the occurrence of a structure which inhibits creep. This could be definitely proved by annealing, which released the residual stresses and produced the same microstructure as in the joined plates. After annealing the same low creep resistance was obtained as with the boiler plates. It is concluded that the welded joint does not endanger the structural stability of the boiler. An accelerated creep test was used whereby the bend in the creep-load curve was utilized for the evaluation of the creep resistance. EF (12)

A Study of Cast Irons with Resistances to High Temperatures (Etude d'ensemble sur les Fontes Résistant aux hautes Températures) T. Boissaux. *Revue Technique Luxembourgeoise,* Vol. 28, Jan.-Feb. 1936, pages 1-13; Mar.-Apr. 1936, pages 33-42. A study of the reasons for changes in a cast Fe exposed to high temperatures which are (1) graphitization or decomposition of the carbides, especially Fe carbide, (2) internal stresses of thermal origin, (3) exterior corrosion and internal oxidation of the material. Methods of determining these factors are described and the influence on them by addition of alloying elements explained. The properties and compositions of heat resisting alloy cast irons are described, especially Niresist and Nicrosilal which can be used for complicated castings and will stand temperatures up to 850° C. 30 references. Ha (12)

Evaluation of Creep Tests (Die Auswertung von Dauerstandversuchen) F. Gentner. *Archiv für das Eisenhüttenwesen,* Vol. 9, Mar. 1936, pages 441-450. An analysis is made of various types of time-deformation curves of various steels at different temperatures and stresses. Experiments confirmed that at a certain test temperature and beyond a certain limiting stress the time-deformation curves are parabolic. Below this limiting stress the curves are logarithmic. Logarithmic curves do not lead to failure; parabolic curves do. Such analyses can be used for determining the creep limit. The limiting creep stress arrived at in this way is one which produces an elongation of 0.2%/yr. Such a value can be used by the engineer for design at elevated temperatures in the same way as the tensile strength is used for design at room temperature. SE (12)

A New Automatically Recording
LEITZ DILATOMETER



For thermal analysis of metals, determination of critical points and coefficients of expansion. Expansion-temperature curves can be automatically recorded with highest accuracy. The instrument combines simplicity of handling, compactness, highest precision and low price. The great sensitiveness in recording the minutest volume changes, the unbelievably low friction in all bearings and the optical precision transmission system make the equipment especially valuable for every Metallurgical Research Laboratory.

Duriron In The Process Industries

●

Corrosion takes its toll by increasing maintenance and repair expenses, adding to the "lost time" total, needlessly wasting material and running up depreciation expenses unduly.

Duriron acid-resisting equipment is well-known to the chemical and allied industries. There is hardly a plant in the United States handling corrosive chemicals that doesn't have some Duriron Equipment.

By the use of Duriron, the costs of production have been lowered perceptibly in many instances. In others it has made commercially practicable processes that otherwise would have been laboratory experiments. Duriron has brought to many industries new economies in time, labor and plant maintenance, freeing Men, Money and Material for profit-producing work.

Pumps, valves, pipe, fittings, exhaust fans, circulating steam jets, mixing nozzles, heat exchangers and many other forms of equipment for acid handling are available in corrosion-resisting Duriron.

If corrosion takes its toll in your plant, you can have the benefit of the experience of engineers who have made a business of combating corrosion. Just write—they will be glad to be of service.

Passivity of Stainless Steels of the 18-8 Type (Contribution à l'Étude de la Passivation des Aciers Inoxydable Type 18/8) J. Hochmann, J. Rist & Andre Michel. *Chimie et Industrie,* Vol. 31, Spec. No., Apr. 1934, pages 625-630. A qualitative study of the phenomena of the passivity of 18-8 steels. The influence of the following factors were studied: action of air with and without heating, effect of certain reactions, such as H_2SO_4, the effect of certain additions (arsenic, ferric salts, HNO_3, etc.) to the reactives. The constitution of steels is reviewed, particularly of Mo and Ni steels. The conclusions indicate that one should never depend on the passivity of the unstable character produced on the surface of a metal by any specific method, such as polishing. The impurities in the acids or attacking liquids produce the damage; that is the factor which the commercial user should always take into consideration, even after tests have been made, for the tests are made with pure acids or liquids. In 18-8 steels the addition of Mo facilitates the establishment of a stable passivity with the sulfonitric mixtures, and increase in the Ni and Mo content favors the passivity with arsenic. MAB (13)

The Oxide Film on Passive Iron. Wilder D. Bancroft & J. D. Porter. *Journal of Physical Chemistry,* Vol. 40, Jan. 1936, pages 37-42. A paper presented at the Twelfth Colloidal Symposium, Ithaca, June 20-22, 1935, states that the evidence brought forward by Evans & Hedges to show that the film on passive Fe is Fe_2O_3 does not prove anything in regard to this. The film making Fe passive and produced by adsorption from a ferrate solution, $K_2O.FeO_3$, is an oxide no higher than FeO_3 (Bennett & Burnham). The film making Fe passive and produced by anodic polarization of Fe in a concentrated solution of KOH is an oxide no lower than FeO_3 (Haber). Since the 2 films are the same, the composition must be FeO_3 (Bancroft & Porter). E.m.f. measurements in HNO_3 of specific gravity 1.20 prove that the same film of FeO_3 is formed when Fe is made passive by adsorption from an alkaline ferrate solution by anodic polarization in alkali, or by treatment with H_2O_2, chromic acid, acid potassium permanganate, or HNO_3 of specific gravities between 1.35 and 1.42. The activation of passive Fe by concentrated H_2O_2 is the result of heating and not of reduction. EF (13)

Determination of Wear Resistance as a Problem of Materials Testing (Die Bestimmung des Abnutzungswiderstandes als Aufgabe der Werkstoffprüfung) H. Meyer. *Archiv für das Eisenhüttenwesen,* Vol. 9, Apr. 1936, pages 501-508. Contains a review of the various wear testing methods. Wear resistance is not a property of the material but depends on the type of wear. Therefore, the wear resistance of different steels cannot be compared on the basis of a single test method. Wear tests are only useful when they closely imitate service conditions. Wear tests should, therefore, be classified not according to the set-up of the apparatus but according to the resulting type of wear, for example whether the wear is wholly metallic or whether oxide layers are formed, and whether severe cold work takes place. SE (13)

Corrosion Resistance of Aluminium and Standard Aluminium Base Alloys. P. Mabb. *Metallurgia,* Vol. 13, Feb. 1936, pages 109-113. Discusses manufacture and properties of Al alloys. The high corrosion resistance of many of the alloys has stimulated their use. Compares corrosion resistance of Al and standard Al alloys. JLG (13)

Subcutaneous Effects During the Scaling of Steel. R. Griffiths. *Industrial Heating,* Vol. 3, Jan. 1936, page 26. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 80R/8. Ha (13)

More Views on Causes of Deposits in White Metal Carburetors. *S. A. E. Journal,* Vol. 38, Jan. 1936, pages 34-35. Discussion of paper by E. L. Baldeschweiler et al, *S. A. E. Journal,* Oct. 1935. Discussers recommend use of $CaCrO_4$ wherever water can collect in order to form inhibitor by dissolution in the water. Photos of fuel pump without and with the inhibitor made up in pellet form fluxed with borax, are shown after test. With the $CaCrO_4$ present corrosion was completely inhibited. Other discussers confirm results of original paper, recommend various types of films and coatings for corrosion protection of die cast carburetors. WB (13)

Headlamps Given Electrolytic Coating of Zinc Phosphate for Rustproofing. *Steel,* Vol. 98, Mar. 9, 1936, page 42. See "Rustproofing Process," *Metals & Alloys,* Vol. 6, Oct. 1935, page MA 418R/4. MS (13)

Handling of Fatty Acids. *Chemical Trade Journal & Chemical Engineer,* Vol. 98, Mar. 20, 1936, page 241. Monel metal resists attack by stearic and oleic acids, and is employed in much apparatus coming in contact with them. Monel metal spindles in stop-valves operating in an atmosphere of C_6H_6 solvent gases, H_2O vapors containing these acids, and NH_3, have given satisfactory service for 15 years. Mild steel spindles were useless in as little as 3 months. MS (13)

Lead Corrosion in Buildings. *Chemical Trade Journal & Chemical Engineer,* Vol. 97, Aug. 9, 1935, page 123. Abstract of *Department of Scientific & Industrial Research—Building Research Board Bulletin* No. 6. Ed. 2. Pb is corroded by CaO, cement, insufficiently seasoned timber, particularly oak, and soil. For preventing corrosion, Pb may be protected by bitumen or felt impregnated with bitumen. Buried pipes may be packed in chalk, limestone, or old well carbonated mortar. MS (13)

Use of Ammonia in Corrosion Prevention. J. W. Smith. *Refiner & Natural Gasoline Manufacturer,* Vol. 14, Aug. 1935, page 395. An automatic system of introducing ammonia into a crude oil to vapor heat exchanger is described. pH was maintained at 7.0; less than 7.0 gave slight corrosion; pH greater than 7.2 will cause corrosion of brass and admiralty condenser tubes and at the same time results in the use of excess ammonia. VVK (13)

RIDING HIGH ABOVE CORROSION!

FOR the manufacture of springs, wheels, pinions, screws, bushings and hundreds of other parts and fittings that must not "freeze" in service when exposed to damp, corroding conditions, remember the name, SEYMOUR PHOSPHOR BRONZE.

This is an alloy of copper and tin purified by the addition of phosphorus. A marked characteristic is its excellent resistance to corrosion. Neither fresh nor salt water moisture affects its service under conditions that would disintegrate many other meals.

This makes it highly dependable for parts in meters, clocks, pumps and scientific instruments used at sea and in other moist areas.

Because of resistance to corrosion, toughness and extreme elasticity, a heavy tonnage of Seymour Phosphor Bronze is made into spring contacts for electric switches. If you have a corrosion or "fatigue" problem, we will gladly send samples for test purposes.

REMEMBER THE NAME

SEYMOUR

PHOSPHOR BRONZE

SPECIALISTS IN PHOSPHOR BRONZE AND NICKEL SILVER

NICKEL ANODES

Ships' Compositions. *Chemical Trade Journal & Chemical Engineer,* Vol. 95, Sept. 7, 1934, page 166. From *Synthetic & Applied Finishes,* Aug. 1934. Deals with formulation of anti-fouling paints. Cu bronze powder is used extensively in Europe for protecting small pleasure craft. MS (13)

Effect of Alkaline Detergents Upon Metals, Aluminum, Copper, Tin, and Zinc. Chester L. Baker. *Industrial & Engineering Chemistry,* Vol. 27, Nov. 1935, pages 1358-1364. Strips of the metals were immersed in the alkali solutions at about 60° C., and observations were made as to the effect of concentration and immersion time. After 24-hour immersion the Na silicates impaired the surface of the metals less than the other alkalies, except Na carbonate toward Zn. Na metasilicate is much used for industrial cleaning of metals, and an increasing silica content seems to give better protection to the metals. MEH (13)

The Handling and Storing of Acids. Thomas J. Dixon. *Chemistry & Industry,* Vol. 54, Dec. 27, 1935, pages 1104-1109. Suitable equipment for handling and storing the following acids is discussed: H_2SO_4, HCl, $HC_2H_3O_2$, HCOOH, and CH_3OOH. The remarks are based on the author's years of experience. Storing and conveying H_2SO_4 below 77%—Pb or TePb. The latter Pb alloy has proven far superior to Pb, due to greater resistance to cracking under stress. Above 77% H_2SO_4-mild steel and cast iron, the latter being better against abrasion. The handling of HCl is extremely difficult, in that non-metals must be used. Stoneware, glass or rubber-lined equipment were standard material until quite recently, when synthetic resins have proven useful and resistant. The handicap imposed by non-metal equipment is most realized in pumps. Ebonite covered shafts and impellers have been successful. Improvement in the physical properties of ebonite and synthetic resins are needed for HCl pumps. Pipe lines of stoneware, ebonite or rubber-lined steel are satisfactory up to 110° C. HNO_3 requires austenitic steel with acid up to 80%, and Al (99.5%) above this strength. $HC_2H_3O_2$ requires Al (99.5%) for cold acids above 90%, and either glass or ebonite lined steel for acids below 90%. HCOOH is the most difficult to handle, few materials being unattacked by either the hot or cold acid, Pb, Ag, stoneware and glass being exceptions. CH_3COOH presents few difficulties when dry, if wet, Pb or rubber lined steel must be used. AAA (13)

Problems of Pipe Line Corrosion Now Being Attacked More Scientifically. Scott Ewing. *Oil & Gas Journal,* Vol. 34, Oct. 31, 1935, pages 32-38. Paper before the Chicago 1935 meeting of the American Gas Association. In removing the third set of coated pipe in the A. G. A. test of pipe coatings the author discussed corrosion problems with a large number of commercial companies. This article contains valuable sidelights from these discussions. In general there seems to be a serious attempt on the part of the gas companies to take advantage of all that is known about coatings and corrosion. Many companies have altered their coating practices within the last few years, probably because of the coating and corrosion research of the National Bureau of Standards, the American Petroleum Institute, and the American Gas Association. Most of the companies, however, have not as yet adopted a definite coating program and policy, probably because they are skeptical as to the necessity or value of the coatings. With the data on repairs and replacements, which the average gas company has, it is usually not possible to demonstrate with a logical argument exactly where coatings should and should not be used. But a study of the data by the company will at least be of considerable help in deciding on where coatings should be used. There is believed to be a general tendency in the industry toward the more extensive use of adequate coatings. VVK (13)

Effect of Mixed Acids Upon Irons and Steels. Justice Eddy & F. A. Rohrman. *Industrial & Engineering Chemistry,* Vol. 28, Jan. 1936, pages 30-31. The results of this study show that (1) high-C steels have a greater tendency to retain their passivity in mixed acids (sulphuric-nitric) than low-C steels; (2) quenched steels exhibit a greater tendency to resist mixed acid than furnace-cooled steels. MEH (13)

The Dissolution of Magnesium in Aqueous Salt Solution. Part IV. L. Whitby. *Transactions Faraday Society,* Vol. 31, Apr. 1935, pages 638-648. Dissolution-time curves up to 24 hours were obtained at 25° in *N*, .01 *N* and .001 *N* solutions of NaCl and of Na_2SO_4, of Mg previously exposed to an indoor atmosphere for 30 minutes, 2 hours, 17 hours, or 21 days. No protection against subsequent dissolution in chloride and sulphate solutions was provided by increasing the thickness of the air-formed film. Visible films, such as those formed in 21 days pre-exposure sometimes produce an increase over the normal rate of dissolution. The effect of concentration of chloride and sulphate solutions on the corrosion rate of Mg was also investigated. Spectroscopic analysis of the 2 samples of Mg used is given. The maxima in rate of solution were observed at certain concentrations, the actual concentrations varying according to the salt, the sample of metal and the time from the start of reaction. The variation in the solubility of Mg hydroxide with the concentration of the salt does not correspond with the corrosion rate-concentration curves. Analyses of the curves have provided additional evidence of the primary preferential hydroxyl ion discharge. Dissolution time curves were also obtained for Mg-Li-Na- and K chloride solutions and the solubility of Mg hydroxide has been measured therein. 10 references. PRK (13)

The Influence of the Electrode Surface on Anodic Processes. O. J. Walker & J. Weiss. *Transactions Faraday Society,* Vol. 31, Aug. 1935, pages 1011-1017. In a recent series of studies on electrical oxidation, Glasstone and Hickling proposed a new general theory for the mechanism of anodic oxidation. They suggested that H_2O_2 was formed as the primary reaction product. This is highly improbable. As H_2O_2 is not formed, it is necessary to account for the addition of salts of Pb, Ag, Mn, Co, etc. bringing about a marked change in the anode process. When passing 450 coulombs at a current density of .25 amps./cm.^{2} between bright Pt electrodes in $CH_3COOK + CH_3COOH$, 1 g. mol./l. each, a definite change in the anode surface took place upon addition of Pb, Mn, Ag and Co acetate to the solution. In explanation it was offered that a distinction must be made between electrodes with high overvoltage and electrodes with low overvoltage. At anodes with high O_2 overvoltage the primary discharge of an anion is favored, whereas at anodes of low overvoltage the OH^- ion is discharged. The resulting OH radicals may then take part in chemical oxidation at the electrode. The effect of adding the metallic salts to the acetate solution, which decreases in the order Pb, Ag > Mn > Cu, Co, Fe, is the formation of oxidized layers on the anode, all of which have a low overvoltage for discharge of OH^-. 25 references. PRK (13)

Corrosion Resistance of Hydronalium, Especially to Seawater (Ueber die Korrosionsfestigkeit von Hydronalium, insbesondere gegen Seewasser) G. Siebel. *Aluminium,* Vol. 17, Nov. 1935, pages 562-567. Due to their resistance to alkalies, the Mg-Al alloys possess an excellent corrosion resistance to seawater which increases with increasing Mg content. The heterogeneous structure of the cast state of high % Mg-Al alloys is practically as seawater-resistant as the homogeneous structure. The kneading alloys of Mg-Al become very temperature-sensitive by cold-deformation which results in severe intercrystalline corrosion. A stable structure can, however, be obtained by heterogeneization below the demixing line. Additions of Zn, Ca, Si, Ti, Cr, strengthen the homogeneous state and render those alloys more resistant to corrosion. Ha (13)

Corrosion of Gas Pipe Line in California. J. C. Albright. *Petroleum Engineer,* Vol. 6, Feb. 1935, pages 36-38. While the H_2S concentration in California gas is extremely small compared to that in some of the gas produced in Texas, corrosion of pipe lines, orifice meter plates, and other pipe line fittings has been great. Practically all the indications of corrosion of pipe lines or fittings found in California gas lines have been where pressures have been high, over 75 lbs./in.^{2} Previous experience had proven that S and O in the presence of water and under pressure were very corrosive. The amount of H_2S and O_2 found in gas varies according to localities from 0.008 to 0.079 grains H_2S /100 ft.^{3} gas and trace to 0.6% O. GTM (13)

Effect of Air Velocity on the Scaling of Iron (Der Einfluss der Luftgeschwindigkeit auf die Verzunderung von Eisen) W. Baukloh & O. Reif. *Metallwirtschaft,* Vol. 14, Dec. 27, 1935, pages 1055-1057. Samples of Armco iron were heated in a quartz tube at 600°, 700° and 800° C. in a stream of air which was pre-heated in another furnace. The velocity of the air was varied from .05 to .7 m./sec. At each temperature the loss in weight due to scaling rose sharply at first with increase in air velocity, then dropped after reaching a maximum, and finally became constant. The maxima and horizontals in terms of weight loss were higher the higher the temperature, and the maxima occurred at higher velocities the higher the temperature. A theoretical explanation is given. CEM (13)

The Atmospheric Corrosion and Tarnishing of Tin. L. Kenworthy. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1331-1345. Tests were carried out on samples in the form of sheet and wire of pure Sn and Sn alloyed with 2.2% Sb and with .2% Cu. Comparison was made with similar samples of Cd, Zn, Ni, 70-30 brass and Cu. Exposures were made indoors, outdoors protected from rain, and outdoors exposed to rain for periods up to about 800 days. Data relative to the change in weight and in tensile strength and in elongation are given in the form of tables and graphs. It was found that in indoor atmospheres Sn and its alloys were attacked less than Cu, Zn or Cd. Pure Sn showed a slight definite superiority over alloyed Sn. The relationship between the weight increment and the time of exposure for Sn in an indoor atmosphere is a linear function except for the first 3 or 4 days. The film formed is probably of a granular nature and not of a continuous protective type. When out-of-doors but protected from the rain, Sn and its alloys were superior to Ni but slightly inferior to Cu. Under these conditions of test the rate of corrosion is closely associated with the deliquescent nature of the corrosion products. Observation showed that Ni formed a more deliquescent corrosion product than Cu and so was corroded more than Cu, but under conditions of complete outdoors exposure without protection from the rain, Ni proved more resistant than Cu. Under these same conditions Sn and its alloys were superior to the comparison materials tested which showed increasing rates of attack in the following order: Ni (least), Cu, brass, Zn and Cd (most). The effect of complete outdoor exposure on the mechanical properties of pure Sn and the 2 Sn alloys was variable. The average value of these 3 materials would appear to indicate that Sn is affected slightly more than Cu and less than Cd. 6 references. PRK (13)

The Corrosion of Tinplate. T. P. Hoar. *Technical Publication of the International Tin Research & Development Council,* Series A, No. 30, 1936, 11 pages. Reprinted from *Proceedings Swansea Technical College Metallurgical Society,* 1936. Consideration is given the corrosion of Sn and of steel, separately and together as tinplate, especially under conditions attained in packing foods in tinned containers. The attack on Sn by dilute organic acids is practically negligible in the absence of air, since H_2 is evolved very slowly from a Sn surface. Exposed steel in tinplate, whether at natural pores or formed through mechanical rupture of the Sn-Fe compound layer, may be protected or the rate of corrosion minimized by the anodic behavior of the Sn under many conditions, as in most canned fruits. The presence of Sn ions in solution also tends to inhibit further attack but these may be removed from solution as insoluble complexes when proteins are present. These proteins act as corrosion inhibitors on steel, however; other constituents, as sulphides, may act as accelerators. Steel composition is also an important factor which must be taken into account. There is some evidence that the presence of Sb or of Bi in Sn aids its resistance to corrosion. Pinholes in tinplate may be substantially reduced by electrodeposition over the hot dipped coating. Lacquering is useful in preventing discoloration of fruits but may increase danger of perforation. BWG (13)

Corrosion of Magnesium and Magnesium Alloys. Hideo Nishimura & Hachie Sawamoto. *Suiyokwai-Shi,* Vol. 8, Dec. 1935, pages 911-922. Corrodibility of Mg and Mg alloys in dilute acidic or NaCl solutions were compared by the measurement of the gases evolved. From the experiments it is concluded that Mn and Zn retard corrosion, but the Al and Cu contents stimulate the corrosion rate of Mg. HN (13)

Protection of Aluminum Alloys. F. C. Pyne & W. L. Fink. *Aviation,* Vol. 35, Feb. 1936, pages 30-33. Discusses testing of Al for corrosion resistance, heat treatment of Al alloys on the market, anodizing process, corrosion inhibitors, spot welding. 3 tables with test results are included in the paper showing (1) atmospheric corrosion of 4 different 14 gage sheets after 1, 2 and 5 years as determined by losses of tensile strength and elongation, (2) alternate immersion tests on same material and (3) effect of 7 different quenching methods on the resistance to corrosion of the 17 ST alloy. Forged — AMSCO-ALLOY Chain!

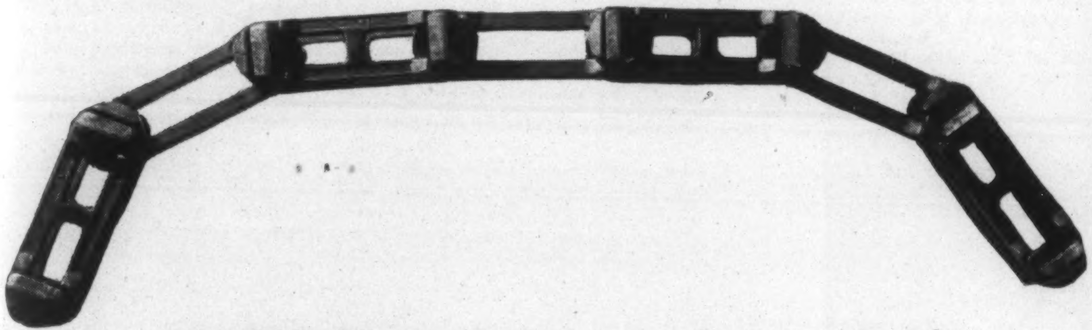
You can now get heat and corrosion resisting rivetless chain with all of the values of AMSCO-Alloy *plus greater strength, wear and corrosion resistance made possible by forging!*

Forging provides better distribution of metal in thin or heavy section parts, greater ductility and minimized breakage, a proper grain flow that provides greater strength, die smooth shaped links and pins that easily fit together, unusual pitch accuracy, and much higher resistance to corrosion.

Available now in Rivetless Class only — AMSCO-Alloy Forged Chain will be made in other classes where quantities warrant.



AMSCO-Alloy is made in an adequate range of analyses to withstand the ravages of high temperatures up to 2100° F., and the destructive action of acids, gases, or other corrosive agents. Correctly applied, it will not bend, crack, warp, scale, or burn.

AMSCO-Alloy is ideally applied to all equipment and in all processes where castings with greatest possible resistance to heat and corrosion are required. Test it to your own satisfaction — write for details!

CORROSION RESISTANCE OF METALS AND ALLOYS

by Robert J. McKay and Robert Worthington

A.C.S. Monograph No. 71, 412 Pages Illustrated $7.00

ALL who have to do with metals—producers, manufacturers, distributors and users—find themselves faced with corrosion problems. This book was written primarily to provide help to a man in this situation.

The total annual loss from corrosion is tremendous. In one case the wrong use of metal led to the scrapping of several hundred thousands dollars worth of equipment inside a month or two, in another the loss was nearly as great. These losses would have been entirely avoided if one or two perfectly simple facts of corrosion had been understood. Losses on a minor scale, due to lack of understanding, are innumerable.

Corrosion can be made an extremely complicated subject. The authors have not let it become so in this book. They have taken as the basis of discussion the simple facts of what a corrosive will do to metals or how a metal will behave in the face of corrosives. Insofar as possible they have expressed this behavior in quantitative terms. Involved discussion of the theories of corrosion have been avoided, yet enough of this has been included to provide background. The approach is essentially a practical one.

Corrosion knowledge is rapidly increasing. It is believed that the present work of about 500 pages may serve for years to come as a pattern into which each newly discovered fact may be fitted and which thus may provide this fact with its true and useful interpretation.

GLANCES AT INDUSTRIAL RESEARCH

by E. R. Weidlein, Director and
W. A. Hamor, Asst. Director

Mellon Institute of Industrial Research, Pittsburgh, Pa.

A COMPREHENSIVE, compact, authoritative, readable account of the recent advances, present status, and future opportunities of industrial research, as discerned at Mellon Institute.

Written especially for business and other busy men, at the request of many of them; usefully informative to all who wish to learn about the value of scientific research in creating new products and new processes and in improving present commodities and their methods of manufacture.

238 Pages, 13 Chapters, 26 Figures Price $2.75

Corrosion of Metals and Alloys in Apiezon Oil. GUNJI SHINODA. *Proceedings Physico-Mathematical Society of Japan,* Vol. 17, Series III, Sept. 1935, pages 367-368. In English. The corrosive action of apiezon oil on low C-steel, Cu, Al, Sn, Pb, Duralumin, 12% Sn-bronze, 40% Zn-brass, constantan, Ni and Sn-solder was studied at 170°-175° C. Al and its alloys are suitable construction materials for the inner part of a pump and steels are preferable for the pump case. The Sn-solder should not be used in the neighboring parts of the heater. Cu tubes, which are widely used up to the present time, were found to tarnish to reddish-brown resulting in a discoloration of the oil. The surface of Ni and constantan became gray after 1 month. Regarding the weight loss due to corrosion, Sn and Sn-solder were closely followed by Pb. WH (13)

Anodic Passivation. W. J. SHUTT. *Transactions Faraday Society,* Vol. 31, Apr. 1935, pages 636-637. Further discussion of the theory of anodic passivation of Au by Shutt and Walton is given refuting the explanations of their data by Armstrong and Butler. PRK (13)

Passivity of Gold. W. J. MÜLLER & E. LÖW. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1291-1299. Experiments with 5 *N* HCl solution showed that the process of the passivation of Au followed the laws of the theory of passivation by surface layers Au exposed to air becomes coated with an oxide layer which is removed during passivation in concentrated acid. The oxide layer of Au is not destroyed by anodic current in diluted HCl. The anodic passivation remains limited to the pores of the natural oxide layer. The relation between initial current and time of passivation is $(i-i_a)t = \text{const.}$, in accordance with the experimental results of Shutt and Walton and of Armstrong. The differences in the behavior of protected and of freely suspended electrodes are of a quantitative nature only. With the protected electrode passivity will be attained sooner or later. For instance, Fe in H_2SO_4 with an initial current density of 18 milliamps./cm.^{2} becomes passive after 22 hours. With electrodes freely suspended or stirred the time of passivation is much longer and there exists a lower limit of the current below which no passivation occurred. There is probably a difference in the character of the natural oxide layers formed on Au exposed to the air and to the "secondary" layer produced by electrolysis. In 5 *N* acid the "secondary" layer is dissolved to a certain degree even during the passage of the current. The alternative formation and dissolution of the oxide layer leads to regular long period oscillations of the current density. In sufficiently diluted acids (1 *N* and .05 *N*) no dissolution occurs. There is no reason to see in the anodic behavior of Au anomalies from the point of view of the theory of passivation by surface layers. 13 references. PRK (13)

Wear of Cylinder Sliding Faces (Ueber den Verschleiss von Zylinderlaufbahnen) RICHARD KOCH. *Automobiltechnische Zeitschrift,* Vol. 39, Jan. 25, 1936, pages 31-36. The factors affecting the wear of cylinder faces of automobile motors, namely the material, correctness of working methods, lubrication and type of fuel are discussed individually. Mn in the cast Fe increases hardness and reduces wear, Si reduces hardness and increases wear, graphite acts like Si, Cr prevents the disintegration of the structure during normalizing up to 600° C. and increases hardness; Ni has no influence on wear. S in moderate amounts increases wear resistance and rarely gives rise to segregations in the casting. When cooling from 100° C. above the solidification point to solidification with a rate of 500° C./min. a cementite structure is produced, with a rate of 200° C./min. a structure of coarse flaky graphite. The mechanical properties of a good cylinder material of 7.6 sp.gr. at the place of greatest wear in the cylinder should be: 220 kg./mm.^{2} Brinell hardness, 85 kg./mm.^{2} compressive strength, 20 kg./mm.^{2} tensile strength, and 40 kg./mm.^{2} bending strength; hardness alone is not an absolute criterion for wear. If the hardness of the piston rings is greater than that of the cylinder the latter wears more and the cylinder wears less if the same material is used for the piston rings. The best difference in hardness is about 50 Brinell units. Addition of Mo to the cylinder material influences formation of graphite only but not wear. Piston rings centrifugally cast have given good results, a good material contains 3.5% C, 3% graphite, 0.5% bound C, 3% Si, 0.7% Mn, 0.3% P, 0.03% S. The piston itself is preferably made of an Al alloy of 84% Al, 14% Cu, 1.5% Mn, 0.5% magnesia, or of a high percentage Si-Al alloy because of its low heat expansion. Mechanical treatment, rules for assembling, and fuel mixtures are described. Ha (13)

The Effect of Five Years' Atmospheric Exposure on the Breaking Load and the Electrical Resistance of Non-ferrous Wires. J. C. HUDSON. *Journal Institute of Metals,* Vol. 56, No. 1, 1935, pages 91-102. Includes discussion. See *Metals & Alloys,* Vol. 6, June 1935, page MA 252L/9. (13)

A Reflectivity Method for Measuring the Tarnishing of Highly-polished Metals. L. KENWORTHY & J. M. WALDRAM. *Journal Institute of Metals,* Vol. 55, No. 2, 1934, pages 247-263. Includes discussion. See *Metals & Alloys,* Vol. 5, Nov. 1934, page MA 540. (13)

14. APPLICATION OF METALS AND ALLOYS

Metallurgical Trends of Chemical Engineering Interest. Clyde E. Williams. *Chemical & Metallurgical Engineering,* Vol. 43, Jan. 1936, pages 17-19. Recent developments in ferrous and nonferrous alloys, in metals for high temperature service and in welding are discussed. PRK (14)

Food-Processing Plant. N. D. Sylvester. *Chemical Trade Journal & Chemical Engineer,* Vol. 96, Jan. 25, 1935, page 57. Abstract of paper read before the Birmingham & Midland Section of the Society of Chemical Industry. See "Metals in the Food industry," *Metals & Alloys,* Vol. 6, Aug. 1935, page MA 340L/1. MS (14)

Materials Approved in England for the Construction of Diesel Engines (In England bewährte Werkstoffe für den Dieselmaschinenbau) *Automobiltechnische Zeitschrift,* Vol. 39, Jan. 10, 1936, pages 19-20. The tendency to use only the best grades of materials in order to economize in weight and space is commented on and a list compiled of materials recommended for the engine frame, the motor, valves, piston and piston rods, fuel transmission, and other parts. Ha (14)

Competition Between Most Suitable Materials for the Design of Instruments (Der Wettstreit um die zweckmässigsten Werkstoffe der Apparatebaues) B. Block. *Chemische Apparatur,* Vol. 23, Jan. 10, 1936, pages 1-4. The selection and availability of material used in the construction of instruments and apparatus, from the standpoint of mechanical strength, safety and endurance is discussed. A table shows the mechanical, physical, thermal, physiological and corrosive properties of metals and non-metals and behavior and mode of application. Ha (14)

The Role of Metals in the Railway Industry. E. J. W. Ragsdale. *Railway Age,* Vol. 99, July 20, 1935, pages 87-89. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 84L/4. CBJ (14)

A.S.T.M. Reviews Constructional Metals. *Iron Age,* Vol. 137, Mar. 12, 1936, pages 55, 81-88. Abstract discussion of papers read at regional meeting of American Society for Testing Materials at Pittsburgh. High strength constructional metals and alloys are discussed. VSP (14)

Metals and Alloys in Locomotive Construction. V. Harbord. *Journal Institution of Locomotive Engineers,* Vol. 26, Jan.-Feb. 1936, pages 46-77. Includes discussion. With modern high-strength alloys, stress concentrations from tool marks, sharp corners, or even date stamps may lead to failure. With mild steel, embrittlement may occur after low-temperature heating (200° C.) if stresses remain after fabrication, as by use of too high a pressure in riveting. Examples of such failures are illustrated. JCC (14)

G. L. CRAIG, SECTION EDITOR

Aluminum Bumpers for Automobiles (Aluminium-Stossstangen bei Personenwagen) W. Schnorrenberg. *Aluminium,* Vol. 18, Feb. 1936, pages 59-60. Successful experiments with Al bumpers of 6 x 50 mm. bars are reported. The whole energy of the car was elastically destroyed in the moment of impact without the passengers being injured or severely shaken or the bumpers breaking, while steel bumpers transmit the impact almost entirely to the passengers. Ha (14a)

Aluminum Alloy Rods for Locomotives—Continental and American Experiences. Brian Reed. *Metal Industry,* London, Vol. 47, Oct. 4, 1935, pages 339-340. The possible use of light alloys for moving parts of locomotives was studied academically for a number of years but the limited space available prevented practical experimentation. The author describes the results of experiments on 2 railroads. A set of duralumin rods were fitted on an engine of the French Eastern Railway in 1931. The rods were designed to replace steel units without any modification and weighed 20% less than the rods replaced. The material was 94% Al, 4% Cu, 0.5% Mn, and 0.5% Mg. They were normalized and aged. The physical properties of the material are given. After running 41,000 miles without giving trouble they were not replaced when damaged in an accident to the locomotive. In America considerable experience was obtained by the Alton & Southern Railroad which has had several installations on 145-ton 10-coupled locomotives for several years. The metal used was 25ST of the approx. analysis 94% Al, 4.4% Cu, 0.75% Mn, and 0.8% Si. The physical properties of the alloy and the weights saved by these installations are given. Examination of failed bars, similar in shape and fittings to the steel bars replaced, showed unequal stress distribution so the bars were redesigned. The new bars show a weight saving of 40% and all lubrication holes and ducts are now located at points of proved low stresses. HBG (14a)

Importance of the Light Metal Cylinder Head for Automobiles (Ueber die Bedeutung des Leichtmetall-Zylinderkopfes in der Kraftfahrt) O. Summa. *Aluminium,* Vol. 18, Feb. 1936, pages 51-53. Experiment and practical application have shown the superiority of the Al-cylinder head in automobile motors over cast Fe; while the h.p./l. cylinder volume was 21.03-21.34 for cast Fe, it is 23.51-24.13 for Al. The fuel consumption is 326 g./brake h.p. in Fe against 293 for Al. The reduction in weight for the engine is about 5%, for the whole car 1%. Correct methods of molding, casting and assembling are described. Ha (14a)

CHACE
THERMOSTATIC
BIMETAL
"It Bends with the Heat"
CHACE BIMETAL used Exclusively IN HUMPHREY GAS UNIT HEATERS

The new Micro-switch safety pilot control of Humphrey Gas Unit Heater breaks the motor circuit and shuts off the gas automatically in event of pilot failure. For the past seven years, Chace Thermostatic Bimetal has been used exclusively as the active element in Humphrey pilot controls. Where automatic action or control of temperature is desired, investigate Chace Thermostatic Bimetal.

BLISS & LAUGHLIN, INC.
HARVEY, ILL. Sales Offices in all Principal Cities BUFFALO, N.Y.

Annual Report of Public Printer, 1935. U. S. Government Printing Office, Washington, D. C. 46 pages. The Printing Office adjusts to composition 9 million pounds of type metal annually. A universal type casting metal was adopted, replacing 4 different formulas previously used for different type of machines. It contains 6% Sn, 12% Sb, 82% Pb. Electrotype backing metal has been reduced in Sn from 4% to 3.5%. The rest is 3.5% Sb, 93% Pb. Stereotype metal has been increased in Sn and Sb content, to 9% Sn, 14% Sb, 87% Pb, to give a better wearing type. Stereotypes can now be Cr plated without first flashing with Cu. It is interesting to trace, in the recapitulation of costs, those ascribable to New Deal agencies. Beside the direct costs, the indirect ones mount up too. A new building project, to cost about 6 millions, for the Printing Office, was inaugurated, the act stating that employment is to be "without reference to civil service laws." HWG (14a)

Aluminium Packing in the Canning Industry. *Aluminium & the Non-Ferrous Review,* Vol. 1, Oct. 1935, pages 17-18. Al packing is particularly suitable for herrings in oil and has also been used in Norway for brisling, kippers, crabs, shrimp, and "fresh-fish." Internal surface protection is not needed for these products. In 1934-35, 8,000,000 boxes of herring were packed in Al. JCC (14a)

Aluminum in the Textile Industry. H. J. Fahrney. *American Silk & Rayon Journal,* Vol. 15, Feb. 1936, pages 33-34, 53. The numerous applications of Al in textile machinery parts are enumerated. It is very widely used in the manufacture of viscose rayon. WHB (14a)

Aluminum Wire, Its Manufacture and Uses. R. T. Griebling. *Wire & Wire Products,* Vol. 11, Feb. 1936, pages 69-71, 106. Development of the Al wire industry is briefly outlined, the properties of Al and Al-Mn, Al-Mg, Al-Cu-Mg, Al-Cu-Mn-Mg, Al-Si-Mg and Al-Mg-Cr alloys are briefly described and some applications illustrated. Ha (14a)

Aluminium and Its Alloys. J. Hinde. *Chemical Trade Journal & Chemical Engineer,* Vol. 95, Oct. 5, 1934, page 237. Discusses their use in construction of chemical equipment. Pure Al resists action of nitric and acetic acids at most concentrations and is used for storage and transport tanks for these acids. It is used for crystallizing pans for citric and tartaric acids. It is satisfactory for use with most fatty acids and has found many applications in the edible oil, brewery, dairy, food, and paint industries. Oxyacetylene and oxyhydrogen processes are best methods of fabrication. Mixture of NaCl, KCl, a fluoride, LiCl, and an acid sulphate makes a satisfactory flux, which must be washed away when welding is completed. For pressure plant, where higher strengths are required, Al alloys containing Mn or Mg are more satisfactory. They have good corrosion resistance. Care must be exercised in using Al and its alloys for high-temperature reaction equipment. MS (14a)

Recent Developments in Light Alloy Pistons. H. J. Mabrey. *Journal Institution of Production Engineers,* Vol. 14, Sept. 1935, pages 495-506. With discussion. The addition of Si to Al alloys reduces their coefficient of linear expansion, and thus increases their "suitability" for piston manufacture. "Suitability" is expressed as thermal conductivity divided by the product of density and coefficient of linear expansion. "Suitability" of cast Fe is 201; of Al alloy with 18% Si, 3% Cu is 897. Heat treatment to increase Brinell hardness is thought unnecessary, since hardness falls in service and anyway is no measure of performance of piston material under working conditions. JCC (14a)

Aluminum as a Native and Substitute Material. The Recent Developments in Its Use (Aluminium als Heimstoff und Austauschwerkstoff. Die neuere Entwicklung seiner Verwendung) Hans Schmitt. *Zeitschrift für Metallkunde,* Vol. 28, Jan. 1936, pages 17-19. A general discussion of modern uses of Al in transportation, in the electrical industry and in static structures. The new uses of Al created by developments in the technique of welding, anodic coating and plating of Al are also enumerated. No specific information is given. FNR (14a)

Old and New Uses of Lead. Felix Edgar Wormser. *Mining Congress Journal,* Vol. 22, Feb. 1936, pages 18-21. Major outlets of Pb are in battery plates, pigments, cable manufacture, and building industries. Among interesting new applications of Pb are in high Pb bearing metals containing Cu; Pb-Ca alloys of twice the tensile strength of common Pb, used in telephone cables; Pb with 0.06% Te, which has high resistance to H_2SO_4; Pb-Sb-Sn and Pb-Sn-Cd alloys of high tensile strength used in pipe manufacture. Pb is also used as anti vibration material in foundations for large buildings and heavy machinery; as a lubricant in drawing steel wire through dies; and in lubricants and greases subject to extra high pressures. Information on uses of historical interest is also given. BHS (14a)

Aluminum in the Transportation Industry. A. H. Woolen. *Proceedings Canadian Railway Club,* Vol. 25, Jan. 13, 1936, pages 30-47. The use of Al and Al alloys in recent applications to railway equipment and airplanes is described. Ha (14a)

50 Years of New Product Development. Francis C. Frary & Junius D. Edwards. *Chemical & Metallurgical Engineering,* Vol. 43, Feb. 1936, pages 64-67. Mention is made of the significant developments during the 50 years in which Al emerged from a jewelry store metal into the position of the fifth metal in point of tonnage. PRK (14a)

Alloys of Aluminum. P. V. Faragher. *Product Engineering,* Vol. 7, Feb. 1936, pages 62-66; Apr. 1936, pages 137-140. Casting alloys of Al, their workability, forming operations, riveting, heat treatment and annealing are discussed; examples for the recently applied impact extrusion process are described. Range of properties of the most used Al alloys, composition and manner of working are tabulated. Ha (14a)

Superiorities of Lead Calcium Alloys for Storage Battery Construction. H. E. Haring, U. B. Thomas, E. E. Schumacher & G. S. Phipps. *Bell System Technical Journal,* Vol. 14, Oct. 1935, pages 699-700. Brief resume of material covered in previous papers. Pb containing 0.10% Ca has a tensile strength of 8000 lbs./in.^{2}, an electrical conductivity 20% greater than 9% Sb alloy, and when used in storage cells gives plates losing only 4 to 5% of their charge per month as compared to 20 to 25% for Pb-Sb alloys. HFK (14a)

All Industry Benefits by Adoption of New Alloys and Better Methods. J. J. Nelson. *Steel,* Vol. 98, Feb. 10, 1936, page 57. Points out importance of keeping abreast of new developments in alloys by account of manufacturer who made considerable saving by substituting lighter and cheaper alloy, which would give as good service, for P-bronze mixture originally intended. Bronze cost 13.95c/lb. just for the contained metals, whereas substitute cost on the same basis, about 9c/lb. Originally estimated weight of 145,000 lbs. was reduced to 133,000 lbs. with the substitute. MS (14a)

New Markets and Uses of Zinc. Russell B. Paul. *Mining Congress Journal,* Vol. 22, Feb. 1936, pages 24-25. Galvanizing is the largest consumer of Zn, taking about 42% of the total production. Discusses use of high-grade Zn (99.99% +) in die casting. Automobile industry is the largest consumer of die cast Zn. High purity metal is also becoming more and more important in galvanizing. More exacting demands have also led to extensive use of high-grade Zn in brass manufacture. Lately an electrothermic process has been developed for the manufacture of Zn oxide. Powdered Zn is a valuable pigment for rust protection and its use is increasing. BHS (14a)

Copper-Nickel (70:30) Alloy. Mason S. Noyes. *Journal American Society of Naval Engineers,* Vol. 48, Feb. 1936, pages 1-18. The reason for the Navy's choice of 70:30 (Cu:Ni) for condenser tubes and other uses for sea water corrosion resistance are detailed in form of results obtained from tests on a number of non-ferrous materials. The corrosion tests included rapid rotation in brackish sea water, slow movement in electrolytic cell containing brackish water, and impingement tests for a jet of brackish sea water. The second test reveals which metal of the cell is anodic since the potential of the cell is measured. A great deal of information on the 70:30 alloy has been culled from the literature showing its good corrosion resistance to salt water, and methods of soldering, bending, etc. are given. The 70:30 alloy is intended to replace for salt water lines the former use of Cu tubing soldered and Sn lined on the inside. WB (14a)

Uses of Copper Tubing in Central Heating Plants (L'Emploi des Tuyaux en Cuivre dans les Installations de Chauffage central) A. Chaplet. *Cuivre et Laiton,* Vol. 9, Mar. 15, 1936, pages 107-108. Advantages of Cu pipes over steel pipes in heating plants are the lower friction coefficient of the liquid on the walls of the tube, lower heat losses by radiation and convection and less stored heat. Methods of installation are briefly described. Ha (14a)

New Uses for Copper. B. B. Caddle. *Mining Congress Journal,* Vol. 22, Feb. 1936, pages 21-23. Mechanical refrigeration offers an important new outlet for Cu, taking about 25,000 tons in 1935. Air conditioning also important consumer. A large tonnage of the metal is now going into house construction; railroads, and automobile manufacturers are also taking large tonnages at present. Recently an electrolytic sheet Cu has been put on the market. This material is excellent for damp-proofing, for built-up roofing, and for interior decoration. BHS (14a)

M. GENSAMER, SECTION EDITOR

Wear Resisting Steel Is Used in Concrete Mixer of New Design. *Steel,* Vol. 97, Nov. 11, 1935, page 42. Mixer drum is made of a steel shell and flanged heads welded together. Shell and mixing blades are of normalized, wear-resisting steel plate containing 0.40-0.50% C. Drum tires are of rolled steel welded to shell. Drive gear and pinion are Ni-Cr semisteel castings. Mixer frame is of structural shapes completely welded. Drum rollers are car-wheel Fe, chilled on face and flanges. They are equipped with 2 bearings each and supported in alloy steel shafts. Drive-shaft is of S.A.E. 1035 steel. MS (14b)

Large Uses of Steel in Small Ways. No. 299. Ground Clamps. *Steel,* Vol. 97, Nov. 11, 1935, page 50. About 60 tons of strip steel and 10 tons of $\frac{3}{16}$" screw-rods are consumed annually in the manufacture of radio ground clamps. Parts are Cd plated. Outlines fabricating operations. MS (14b)

Story of the House That Builds Jacks. W. G. Gude. *Steel,* Vol. 97, Nov. 18, 1935, pages 35-36. Outlines methods of Walker Mfg. Co., Racine, Wis., in manufacturing automobile jacks. Standard and base of pressed steel jack for light cars are stamped from steel strip. Gear and pinion are malleable Fe. Outer screw of double screw is made of hot-rolled S.A.E. 1112 Bessemer screw-stock. Inner screw is turned from high-C steel. Screws used on larger jacks are heat treated and hardened. Ball-bearing races are stamped from hot-rolled, pickled, and oiled strips. Cap on top of screw is stamped from hot-rolled steel and is carburized to resist wear. Caps on heavier jacks are drop forged. Base and standard of jacks with a capacity of more than 1 ton are of malleable Fe. Oil reservoir of hydraulic jacks is of welded tubing, while pressure cylinder is unannealed seamless tubing. Cd plating is used to prevent seizure of piston. Service jacks are largely malleable castings, with some drop forged and rolled steel. MS (14b)

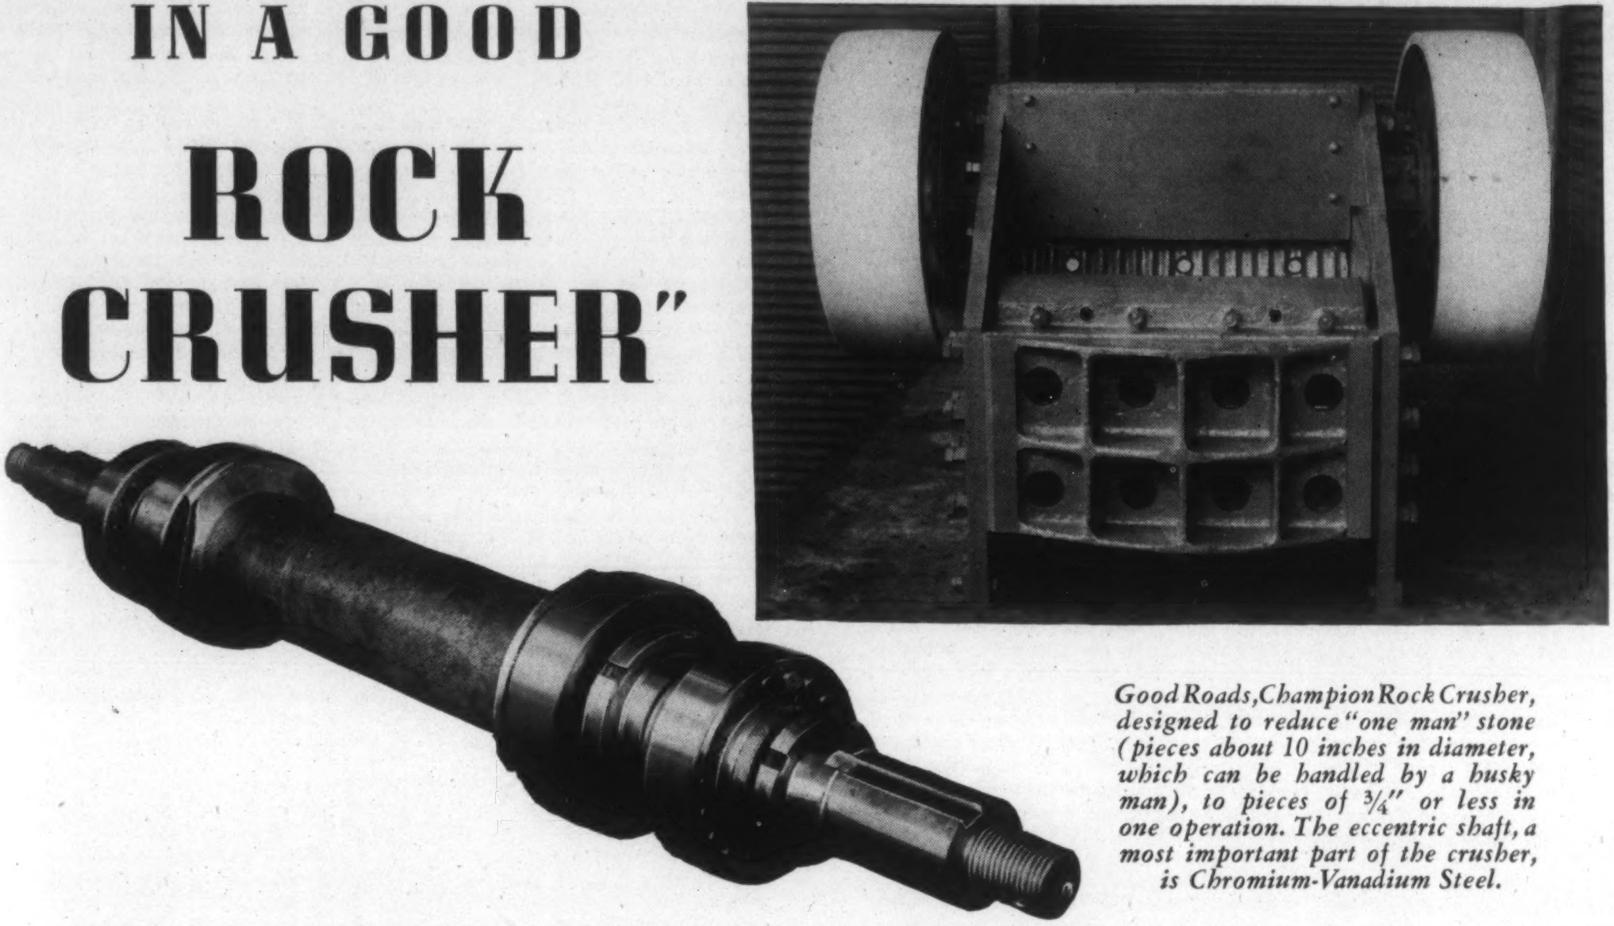
Fit Product to Season, Says Sheet Metal Fabricator. A. H. Allen. *Steel,* Vol. 97, Sept. 9, 1935, pages 36-38. Describes fabrication, finishing, and assembly of beverage coolers and refrigerators by the Lima Metal Products Inc., Lima, Ohio. Cold rolled sheet steel, vitreous enamel stock, and galvannealed stock are used. Some parts are spot welded. Exterior is given a crinkle finish by spraying a mixture of china-wood oil, asphaltum, and varnish gums, followed by baking at 350° F. in a continuous oil-fired oven. Exterior hardware is Cr plated. Domestic refrigerator cabinets are finished in synthetic enamel. Forming dies are largely of Ni cast-Fe or meehanite, with oil-hardening tool-steel inserts where excessive wear is encountered. MS (14b)

The Story of the Ford Cast Crankshaft. Edwin F. Cone. *Metals & Alloys,* Vol. 6, Oct. 1935, pages 259-263. Cast crankshafts have been used by Ford for 3 years and following composition is used at present C 1.35-1.60%, Mn 0.60-0.80%, Si 0.85-1.10%, Cu 1.50-2.00%, Cr 0.40-0.50%, P 0.10% max., S 0.06% max. Pouring is done in dry sand molds containing 4 shafts. Castings and finished shafts both weigh less than rough forgings and shafts finished from them. WLC (14b)

"There Can Be No Weak Spots

IN A GOOD

ROCK CRUSHER"



Good Roads, Champion Rock Crusher, designed to reduce "one man" stone (pieces about 10 inches in diameter, which can be handled by a husky man), to pieces of ¾" or less in one operation. The eccentric shaft, a most important part of the crusher, is Chromium-Vanadium Steel.

Ask the Good Roads Machinery Corporation, of Kennett Square, Pennsylvania, why they use Chromium-Vanadium Steel in the eccentric shaft of their heavy duty crusher and they will tell you, as they told us: "There can be no weak spots in a good rock crusher; therefore we spare nothing when it comes to materials that will provide the required strengths for this severe service. We tried various other steels for this unit, (i. e., the eccentric shaft), but found chromium-vanadium steel the most satisfactory and adopted it as standard in these machines."

Vanadium Steel has solved many a problem for designers of heavy duty machinery. The useful strength of Vanadium Steel, its exceptional toughness and high resistance to fatigue make it ideal for shafts and other severely stressed parts.

Whether your steel problem involves heavy duty forgings or light parts, the Metallurgists of the Vanadium Corporation will welcome the opportunity to confer with you.

Forging Logging Tools. J. B. Nealey. *Heat Treating & Forging*, Vol. 21, Dec. 1935, pages 567-568. Describes procedure and equipment of the Dixie Logging Tool Co., Chattanooga, Tenn. Tools are made from C steels and tool-steels. Gas-fired forging furnaces and mechanical hammers with accurately cut dies are used. MS (14b)

Slab Yard Cranes Are Built with Hydraulic Brakes. *Steel*, Vol. 97, Sept. 23, 1935, pages 143, 149. Describes cranes, of arc-welded steel construction, which serve slab yard of a 76" hot strip mill in the Youngstown district. MS (14b)

Alloy Steels Used in Oil Refinery Distillation and Cracking Equipment. J. C. Morrell, L. A. Mekler & Gustav Egloff. *Oil & Gas Journal*, Vol. 34, June 20, 1935, pages 50, 52, 62, 64. A comprehensive and valuable review of alloy steels used in oil distillation and cracking equipment. VVK (14b)

Stainless Steel in the Milk Industry. J. A. McWilliam. *Milk Industry*, Vol. 15, May 1935, page 75. Steel containing 18% Cr and 8% Ni is the most satisfactory metal for tanks, vats, coils, and pipes, and is replacing other materials in all types of milk containers. A historical and descriptive discussion. GPS (14b)

Nickel-Bearing Alloys in the Production and Refining of Petroleum. Byron B. Morton. *Mining & Metallurgy*, Vol. 16, Oct. 1935, pages 411-414. A general review of the use of Ni cast Fe, Ni-resist, Monel metal and Cr-Ni alloys in the production and refining of petroleum. VSP (14b)

Manufacturing Airplane Struts. F. L. Prentiss. *Iron Age*, Vol. 136, Dec. 12, 1935, pages 20-24, 94. Describes the construction of shock absorbing struts by the Cleveland Pneumatic Tool Co. Strut parts are made of 4130 x Cr-Mo steel made in electric furnace. Composition of steel is: 0.25-0.35% C; 0.40-0.60% Mn; 0.040% max. P; 0.80-1.10% Cr; 0.15-0.25% Mo; and 0.15% min. Si. Stock is received annealed having tensile strength of 90,000 lb./in.^{2}, Brinell hardness of 177-180 and C scale Rockwell hardness of 14-15. Tensile strength is increased by subsequent heat treatment to 150,000-180,000 lb./in.^{2}, Brinell hardness 377-380 and C scale Rockwell 45-46. Parts are atomic H_2 welded, machined and plated. VSP (14b)

Application of Alloy Steels. H. W. McQuaid. *Canadian Chemistry & Metallurgy*, Vol. 20, Jan. 1936, pages 19-20; *Heat Treating & Forging*, Vol. 22, Jan. 1936, pages 19-24. Address delivered before the American Institute, Dec. 15, 1935. Deals with effect of alloying elements on hardening, Mn as an alloy, a comparison of alloy- vs. C-steels for gears, and a discussion on the strength of the steels at high temperatures. WHB + MS (14b)

Care, Inspection and Maintenance of Lifting Equipment. A. Taylor. *Mechanical Handling*, Vol. 22, Mar. 1935, pages 67-71, 131-136. See "Crane Ropes, Chains and Hooks," *Metals & Alloys*, Vol. 6, Sept. 1935, page MA 377L/6. JCC (14b)

The Era of Stainless Steel. L. M. Angus-Butterworth. *Sheet Metal Industries*, Vol. 9, Nov. 1935, pages 699-700. A general discussion of the development of stainless steels and their increasing use. AWM (14b)

Manufacture and Finish of Golf Shafts. R. P. Brown. *Iron Age*, Vol. 136, Oct. 17, 1935, pages 34A-34B, 70-71. Describes manufacture and finish of steel golf shafts by the American Fork & Hoe Co. Cold drawn tube stock is cut to length, fully annealed and quenched in H_2O. Quenching consists of 3 stages, the last being clear fresh H_2O. Following this tubes are cut to length and Cu flashed in $CuSO_4.5H_2O$ solution prior to drawing. Cold draw benches reduce tubes to desired thickness. On leaving stepping press shafts are tempered. After testing the shafts are Cu or Cr plated. VSP (14b)

Nitricastiron Cylinder Sleeves. A. T. Colwell. *Iron Age*, Vol. 136, Dec. 19, 1935, pages 31-33. Describes nitricastiron cylinder sleeves for bus and truck motors. Tests indicate that nitricastiron sleeves increase mileage to a total of 300,000 to 400,000 miles without any service being necessary. Nitricastiron is a special grade of Fe which is nitrided on the bore surface. Hardness will be from 800 to 1000 Brinell for a depth of 0.004" to 0.006". Analysis is as follows: Total C 2.93%; graphite C 2.31%; combined C 0.62%; P 0.058%; S 0.029%; Mn 0.76%; Si 2.69%; Cr 1.28%; V 0.16%; Mo 0.24%; and Al 1.01%. Cylinder sleeve castings are cast centrifugally. Growth during nitriding is allowed for, which may be as high as 0.001". VSP (14b)

Prefabricated Houses for Low-Price Field. *Steel*, Vol. 98, Feb. 3, 1936, page 46. Describes house developed by General Houses, Inc., Chicago, designed to sell at $2500-$4900, erected and equipped. Frame is of Cu-bearing steel beams and columns. Exterior walls are of asbestos-cement and plywood panels with Al foil insulation. Interior partitions are made of plywood panels and Cu-bearing steel studs. Roof consists of panels of galvanized Cu-bearing steel with joints sealed with steel flashing. Steel is used also for interior trim, door and window frames, and screens. MS (14b)

Speed and Rowboats Are Built of Steel Sheets. *Steel*, Vol. 98, Jan. 13, 1936, pages 30-31. Describes design, and fabrication of boats developed by Gil-Boat Co., Holland, Mich. MS (14b)

15. GENERAL

RICHARD RIMBACH, SECTION EDITOR

Mineral Chemistry. Radioelements, Rare Gases, General Study of Alloys (Traite de Chimie Minerale. Vol. XII. Radioelements—Gaz rares. Etude generale des alliages) Edited by Paul Pascal. Masson et Cie., Paris, 1934. Cloth, 6¾ x 10 inches, 856 pages. Price 180 Fr.

The book under discussion has been written by different authors, each a recognized specialist in his selected field; a method of book writing which is the only one possible in our diversified and enormous field of science.

The first hundred pages or so of this book give rise to the most optimistic expectations. These pages are devoted to radioelements, are expertly written by M. Curie and J. Escher-Desrivieres, and contain much interesting material, perhaps not new to the expert physicist and chemist but indeed most ably summarized for the attention of the interested scientific reader. A short bibliography, quite exhaustive, is appended. Unfortunately this chapter ends with developments up to the year 1931—usual and unfortunately unavoidable shortcoming of any monumental volume.

The chapter on rare gases that follows has an excellent bibliography—its best point. Surely a subject as important and as little known to general scientific readers deserves a more full treatment. Books on phase rule and its application already written (for example, the book by Masing or Marsh) present a more comprehensive study of this subject than the chapter by Portevin written for this book. Prof. Portevin adopted a commendable and rather unusual—at least for English writers—course; namely, that of introducing and discussing the question and matter of diffusion (both liquid-solid and solid-solid) in its proper place, right after the presentation of the principle of solid solutions and laws governing the formation of the latter.

The presentation of the subject is accomplished without recourse to thermodynamics—again a commendable feature; I hasten to add that this is the personal view of the reviewer. As a consequence the average metallurgist will enjoy this chapter and profit by its careful study without experiencing the feeling of self contempt for not being chummy with free energies and entropies. It really is a good chapter, and it would have been made even better if it contained illustrations so desirable in such sub-chapters as the one on segregation and liquation.

Since the year 1927, Volume II of International Critical Tables has been a much consulted book; it was, to the best of the reviewer's knowledge, the only publication in which various metallic systems were summarized and systematized. Personally, I feel somewhat guilty in pushing aside this useful volume, but it must relinquish its place to Volume XII of "Trait de Chimie Minerale," the book under review. The latter contains infinitely more systems (diagrams) carefully arranged; as a summary it is an excellent one. However, as a source of reliable statements it varies from one sub-chapter to another. Particularly good, carefully arranged, and critically surveyed are sub-chapters on copper and antimony. (Imagine a whole sub-chapter devoted to antimony!) Equally good is the sub-chapter on aluminum, containing many corrected diagrams (in comparison with Critical Tables) such as aluminum-zinc or new ones such as aluminum-calcium.

From reading the sub-chapter on iron alloys one might suspect that ferrous metallurgy remains in a state of stagnation. Granting the obvious and enormous difficulties encountered in publishing a book of this sort (it is humanly impossible to keep up to date unless we stop research for two or three years!), yet there are certain things which must be incorporated if they appear in press prior to final publication of the book. To talk of iron-carbon alloys in old terms and disregard the study of rates of reaction is unpardonable.

Inclusion of incomplete or incorrect diagrams for iron-nitrogen, iron-nickel, iron-manganese and other alloys is regrettable. Perhaps a supplement or appendix to this otherwise valuable book would be possible.

A minor criticism: Is it not time that we decided on universal chemical symbols? Even those who read French well enough to enjoy this treatise may be baffled by Glucinium and by the symbol Tu instead of W as is used elsewhere for Tungsten (Wolfram).

This book should be in every reference library, and if one can find somewhere enough francs (180 francs is the price of the book) to pay for this volume, even though it may sound high, by all means pay it. V. N. Krivobok (15) -B-

Textbook of Physical Chemistry (Lehrbuch der physikalischen Chemie) Vol. 5, Part 2. Karl Jellinek. Ferdinand Enke Verlag, Stuttgart, 1935. Paper 6½ x 10 inches, pages 289-576. Price 27 RM.

This part covers the structure of atom shells and cores. Various ideas as to atomic structure, protons, neutrons, positrons, etc. are collected into convenient form, with large doses of mathematics, for those who wish to assimilate them. The last few pages deal with stereochemistry, optical activity, etc. along classical lines of organic chemistry, and this is apparently to be carried farther in the next part.

The metallurgist's interest in the subjects dealt with is usually rather indirect. H. W. Gillett (15) -B-

Transactions American Institute of Mining & Metallurgical Engineers, Vol. 117, Institute of Metals Division. Published by the Institute, New York, 1935. Cloth, 6¼ x 9¼ inches, 418 pages.

While advance copies of most of the papers in the Transactions have been available, it is always of interest to study the bound volume, not only for the discussions, but also to get a picture of what the non-ferrous metallurgists are dealing with. Besides the Division lecture on Gases in Metals by Edwards of Swansea, the volume contains 22 other articles.

Several deal with structure as revealed by X-ray data. Several others deal with equilibria in such systems as Mo-C, Co-O, Cu-Sn-Be, Cd-Sb. A few deal with precipitation hardening phenomena, one being a very important article on Al-Cu-Ni. Another noteworthy article sets forth the thermal and electrical conductivities of Cu alloys. A new tool, the polarization microscope and the application of another, spectrographic analysis, to die castings, are described. Zinc, aluminum and brass die castings are dealt with. Casting properties of metal silvers, properties of Pt metals, and discussion of welded pressure vessels and of oil-production equipment give a practical tone. With a few exceptions the high-brow articles come toward the front and the more practical ones toward the back. This may mean that the Institute feels that its best foot is a high-brow one, if you don't mind unorthodox physiology, or that the writers on theoretical phases got their papers in first.

Anyhow, there is much in the volume that is of direct practical application. H. W. Gillett (15) -B-

Handbook of Chemistry and Physics. 20th Edition. Chas. D. Hodgman, Editor-in-chief. Chemical Rubber Publishing Co., Cleveland, Ohio, 1935. Fabrikoid, 4½ x 6¾ inches, 1951 pages. Price $6.00. The 20th edition of this handbook shows an increase of 18 pages over the last edition. The new and revised tables in this edition are: Physical Constants of Organic (8988) Compounds; Formula Index of Organic Compounds; Pronunciation of Chemical Words; Rules for Naming Organic Compounds; Prefix Names of Organic Radicals; Properties of Amino Acids; X-ray Spectra; Magneto-Optic Rotation; Colorimetry; and Photometry. The X-ray spectra data were revised by Prof. J. M. Cork, University of Michigan to conform to the results of recent determinations. Richard Rimbach (15) -B-

Processes for the Volatilization of Metals with Special Reference to the Manufacture of Zinc Oxide (Die Metallverflüchtigungsverfahren mit besonderer Berücksichtigung der Herstellung von Zinkoxyd). Otto Barth. Verlag von Wilhelm Knapp, Halle (Saale), 1935. Paper, 6⅞ x 9½ inches, 234 pages. Price 15.50 RM.

This book is No. 4 of a series of "Monographs of Metallurgical Practices." Its emphasis is placed on the manufacture of Zn oxide by means of volatilization. The volatilization of other metals, however, is also discussed briefly.

The term "volatilization processes" as used in this book comprises all those processes in which metals or metallic compounds are vaporized from metallic or nonmetallic raw materials to be then recovered in the form of metallic compounds. The emphasis, however, is always placed on the vaporization stage and not on the recovery or the collection of the reaction product.

To mention an example, the book deals for instance with the processes for the volatilization of Zn from a low grade ore, for the purpose of concentrating it in the form of Zn oxide. A discussion of the working of complex ores is also included insofar as it offers a means of separation and a supplement to flotation.

In general, this book is well written and contains a mass of detailed technical data of considerable value to the practical man. Some of the tables, however, are not as clear as might be desirable. Frequently, the meaning of column headings, figures, etc., can be ascertained only through careful study of several paragraphs preceding or following the table. Precise titles and accurate column headings would add considerably to the value of the book as a reference or handbook for the practical metallurgist.

In order to give the reader a better idea of the scope of this book, the main chapter headings are given below.

I—The relation of the volatility of metals and metallic compounds to vapor pressure, temperature, surface area and time.

II—The thermic data of the most important volatile metals and metallic compounds, including arsenic.

III—The metallurgical reactions taking place in volatilization processes.

IV—The raw materials.

V—The volatilization processes.

VI—The manufacture of paint oxide.

VII—The collection of the oxides.

VIII—The properties and testing of Zn oxides.

IX—The evaluation of Zn oxide and Zn white.

X—The manufacturers of Zn oxide and Zn white.

XI—Statistical data.

XII—The patents relating to the volatilization of metals issued in Germany since 1920.

The chapter on paint oxides, their properties and testing methods, is of course applicable primarily to German products and practices but will prove of considerable interest to the American metallurgist and Zn oxide manufacturer.

The appendices listing the manufacturers of Zn oxide, giving statistics on the production, exports, imports, and prices of Zn, Pb and Sn, and reviewing all patents dealing with the volatilization of metals issued in Germany since 1920 are not the least important and useful parts of this book.

Style and language of this book are a pleasant surprise to the foreigner who has had barely enough technical German to pass a college examination. Although grammatical constructions and almost endless sentences so characteristic of technical German are not entirely absent from this book, they are not nearly as frequent as in most German technical or scientific literature. Americans therefore should have little or no difficulty in finding their way through this book.

A. C. Elm (15) -B-

The Way of Iron (Der Weg des Eisens) Fritz Toussaint. Verlag Stahleisen. Düsseldorf, 1935. Paper 8¼ x 11¾ inches, 56 pages. Price 0.90 RM. A condensed description of the production of iron and steel from the ore to the finished product. The book was prepared for those who are not familiar with the manufacture and working of iron and steel. The book is profusely illustrated.

Richard Rimbach (15) -B-

Journal of the Institute of Metals, Vol. 57, No. 2. Institute of Metals, London, 1935. Cloth, 5¾ x 8½ inches, 311 pages.

In reviewing bound volumes of transactions of technical societies, we are often moved to comment on the value of the discussions, which make the final volumes so much more useful than the preprints. This is supremely the case in the instance at hand. Brownsdon's lecture on "Metal Melting, Its Effect on Quality," is followed by over 20 pages of discussion which deals with such topics as filtration of molten metals, use of scrap, solubility of impurities, vacuum melting, hydrogen atmospheres, gas solubility, hydrogen unsoundness, permeability of crucibles to gases, reactions with refractories, deoxidizers, fluxes, etc., all in relation to non-ferrous melting, that are valuable and thought-provoking. Cook's paper on metal losses in melting brass is accompanied by 10 pages of discussion on fluxes, charcoal and coal covers, order of charging, etc. in electric and crucible furnaces.

Some of the other papers on porosity of bronze ingots, properties of bronzes, straining of Pb, stress distribution in flexure of Pb, age-hardening in Cu-Ni-Si alloys, production of powdered solder-like alloys, failure of a gold fuse link in a Ni Cr resistor, corrosion and protection of Mg, and a few X-ray papers, are also followed by discussion.

The proportion of space given to problems of a highly practical nature is unusually large. The brass foundry superintendent will find this volume of as much interest as will the metallurgist. H. W. Gillett (15) -B-

The Pretoria Iron and Steel Works. *Engineer*, Vol. 161, Jan. 24, 1936, pages 94-97. Illustrated article describing the Pretoria Works of the South Africa Iron, Steel and Industrial Corporation. The coke-ovens, blast-furnaces, steel-furnaces and rolling mills and the by-products plant are described. Statistics of the materials consumed by these departments as well as production and revenue figures are given.

LFM (15)

Mechanical Technology of Metals (Mechanische Technologie der Metalle) Hermann Meyer. Dr. Max Jänecke, Verlagsbuchandlung, Leipzig, 1935. Paper, 5¾ x 8¼ inches, 355 pages. Price 6.20 RM. In this new edition attention is given to the work of the German Standards Committee. As the economic situation in Germany necessitates industry freeing itself of using foreign materials, the importance of "home" materials is mentioned where suitable.

An addition made since the last edition, is a discussion of non-metallic raw materials. Molded compounds are considered as they have displaced metals.

The contents of the book are as follows: I. The metals of importance in machine construction, Iron, the production of Pig Iron, Steel, Non-ferrous metals and alloys, the testing of metals. II. The Forming of Metals by Casting, the Iron Foundry, the Steel Foundry, Non-Ferrous Castings. III. The Forming of Metals by Working, Forging, Hot Pressing of Non-ferrous Metals and Alloys, Rolling, Manufacture of Tubes, Wire Drawing, Upsetting. IV. Welding. V. Soldering. VI. Hardening. VII. Non-metals important for Machine Construction, Wood, Leather, Rubber, Molding Compounds, Lubricants. Richard Rimbach (15) -B-

Department of Scientific and Industrial Research, Report for the Year 1934-35. His Majesty's Stationery Office, London, 1935. Paper, 6¼ x 9½ inches, 185 pages. Price 3s.

In the introduction, Lord Rutherford points out that 13 research associations in England are earning grants from the government, based on obtaining support from the industry concerned. About £200,000 are thus available from the government. The metallurgical research associations are British Non-Ferrous Metals, British Cast Iron, and British Iron & Steel Federation.

The metallurgical research under the Department is, of course, chiefly carried out at the National Physical Laboratory. A separate report on the N.P.L. work has already been published. Some of the work of other organizations that is of metallurgical interest is: the Food Research Board made tests showing that aluminum cans are unsuitable for canning fruits, and that small amounts of Sb or Bi in Sn inhibit attack by dilute citric acid; the Building Research Station is studying high tensile structural steel; the Chemical Research Laboratory is working on immersed and atmospheric corrosion, with a special investigation on boiler tubes; supra-conductivity is being studied at Cambridge, the Cast Iron Association is working on methods of control of graphite structure, on quality of coke, etc.; the Iron & Steel Federation on ingot molds, oxygen determinations, etc., and the Non-Ferrous Association is engaged on some 50 projects.

The Refractories Research Association is concerned with blast furnace refractories; the Paint Association has published a paper on painting of galvanized iron, while the Automobile Engineers Research Committee is studying cylinder wear and corrosion, valve seat wear and lubricating oil consumption. H. W. Gillett (15) -B-

Metallurgical Section, International Congress of Mines, Metallurgy and Applied Geology, Vol. 1. (Congrès International des Mines, de la Métallurgie et de la geologie Appliqueé. Secion de Métallurgie. Tome 1.) Revue de Métallurgie, Paris, 1936. Paper, 9 x 11 inches, 476 pages. Price 86 Fr.

This volume includes 44 articles by well known authors from many countries, including J. F. Thompson, E. C. Bain and Prof. Sauveur from the U. S., Hadfield, MacNaughtan, Haigh, Evans, etc. from England, Benedicks from Sweden, Giolitti from Italy, Ros and Eichinger from Switzerland, to mention only a few, while Portevin, Chevenard, Perrin, Guillet, Ballay, Billiter, etc. are among the French authors. A wide range of subjects is covered, blast furnace design, electroplating, purified Al, flaky steel, Mo, Al, Mg alloys, oxide coatings on Al, electric cast iron, alloy iron, malleable, die castings, aging of steel, welding, forgeability, nitriding, high temperature testing, fatigue testing, etc., etc.

The articles are appearing in Revue de Métallurgie and are abstracted from that source. H. W. Gillett (15) -B-

Nickel Production in Brazil (Produccao de Nickel no Brasil) *Chimica e Industria,* Vol. 3, Oct. 1935, page 137. Brief statistical data of deposits of Ni ore in the various states of Brazil. The average content is 4%, but there exist some deposits with 4-8%, and even 14%. The export in the years 1933 and 1934 amounted to 470,000 and 386,505 kg. respectively. Ha (15a)

The Steel Output and Outlook. *Engineering,* Vol. 140, Dec. 27, 1935, pages 696-697. The world's production and consumption of steel is greater now than in 1913 in spite of present-day business difficulties. Except for France, Belgium, Luxemburg and India, the increased tonnage is used for home consumption. The United States is exporting only 1/3 of her pre-war tonnage, Germany and Great Britain little more than ½ of their 1913 tonnage. Belgium is exporting less than twice its 1913 tonnage, France 3 times and India 6 times as much as in 1913. LFM (15a)

The Science of Metals Grows Apace—Many New Alloys and Methods of Treatment. *Mining & Metallurgy,* Vol. 17, Jan. 1936, pages 42-49. A number of contributions by various authorities on non-ferrous metals and alloys. "Nonferrous physical metallurgy," by Robert F. Mehl; "Secondary metals more closely examined" by W. Romanoff; "New lead and tin alloys in batteries, bearings, and bullets" by George O. Hiers; "New and old aluminum alloys meet a rapidly expanding demand" by L. W. Kempf; "Brass and copper mills continue efforts to secure highest quality in products" by John L. Christie; "Wide diversification in use leads to biggest year in nickel" by Robert C. Stanley; "Die castings and electrogalvanizing boost use of purest zinc" by W. M. Peirce; "Several new developments in use of silver and precious-metal alloys" by Robert H. Leach; and "Magnesium-alloy products improve in quality and size" by John A. Gann. VSP (15a)

35,000,000 Tons, 1936 Ore Estimate; Deals in Vessels. *Steel,* Vol. 98, Feb. 17, 1936, pages 27-28. Includes review of Lake Superior Fe-ore industry. Tabulates shipments by the different mines in 1934 and 1935. Total in 1935 was 28,503,501 tons compared witht 22,063,824 tons in 1934. In 1935, 1,717 tons of lake ore were used to make 1 ton of pig-Fe produced with lake ore. MS (15a)

Further Progress in Production and Use of High-Grade Zinc—Oxide Situation Interesting. Frank G. Breyer. *Mining & Metallurgy,* Vol. 17, Jan. 1936, pages 24-26. Following developments in the field of metallic Zn during 1935 are listed in order of their importance: (1) Construction of further continuous vertical retort smelting capacity in United States and Germany; (2) expansion of fractional distillation capacity; (3) expansion in Zn-base die casting in United States and abroad; (4) wide acceptance of heavy galvanizing by steel industry; (5) construction of first commercial wire electroplating plant for putting on heavy coats of pure Zn; and (6) use of Zn dust as reducing agent in organic chemical industry. In the field of Zn compounds: (1) Decrease in use of ZnO in rubber compounding; (2) wider appreciation of leaded ZnO in paint; (3) threat of Ti inert combination to lithopone in the bulk whitening field; and (4) threat to TiO of ZnS as better value where concentrated whitening powder is needed. Wanted:—By a well-known manufacturer of Heat and Acid Resisting Castings Sales Representatives who are acquainted with buyers and operating heads in the Steel, Automobile, Chemical and Oil Industries in the following territories: New York, Boston, Philadelphia, Chicago, Cincinnati, Houston and Birmingham. No objection to one or two more lines. Reply giving references and full information as to qualifications. Address Box MA-2, Care of Metals & Alloys, 330 W. 42nd St., New York, N. Y.

REPRESENTATIVE WANTED—A manufacturer of heat resisting alloys and castings seeks representation in both the Philadelphia and New England territories. We are looking for a manufacturer's representative now calling on metal working plants who has the entree to the heat treating supplies market. Write Box No. MA-3, METALS & ALLOYS, 330 42nd Street, New York, N. Y.

Junior Executive Available—M. I. T. Graduate. General engineering experience, Chase Brass and Copper Company. Purchasing chemicals and equipment, R. H. Macy and Company. Single, Christian, references. Box No. MA-4, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

POSITION WANTED: INSPECTOR, SUPERVISOR or INSTRUCTOR of WELDING. Specialized 8 years in arc welding. Knowledge of Metallography, Heat-Treating and Physical Metallurgy. Capable of performing tests and conducting investigations of Weld-Metal. Sales experience. Member of American Welding Socy. and American Socy. for Metals. Good Linguist. Consider position outside U. S. Available July First. Address box MA-6, care of METALS & ALLOYS, 330 W. 42nd Street, New York, N. Y.

FURNACE DESIGNER—Wanted by a manufacturer of electric furnaces. Man with experience designing and estimating electric heat treating furnaces; batch, continuous and salt bath. Give full details of experience, references and salary desired in first letter. Position will be permanent to right man. Address Box No. MA-7, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

METALLURGIST AVAILABLE.—A young man, a graduate Chemical Engineer now employed, who has had more than seven years of experience covering all phases of both ferrous and non-ferrous physical metallurgy, including a knowledge of materials and their applications, heat treating, metallurgical, physical, and corrosion testing, is seeking a new connection with opportunities for increased responsibility and salary. For further information write to Box MA-8, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

MARKET RESEARCH SPECIALIST with a good technical background. Complete developing and marketing experience on electrical and chemical specialties and instruments. Salary or fee basis. Box MA-9, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

Iron and Railroad (Eisen und Eisenbahn) G. HAMMER. *Stahl und Eisen,* Vol. 55, Dec. 5, 1935, pages 1451-1455. Historical, on 100th anniversary of the German railways; 40 million tons of steel have been used to-date in the German railways. SE (15b)

Aluminum—From a Chemical Element to an Industrial Metal. ZAY JEFFRIES. *Iron Age,* Vol. 137, Feb. 20, 1936, pages 22-28. An historical review of Al, considering the work of various investigators, with special reference to the work of C. M. Hall. In addition discusses the magnitude of the industry and the industrial applications of Al products VSP (15b)

Skyscraper Born 50 Years Ago; Raised on Steel. V. G. IDEN. *Steel,* Vol. 98, Feb. 24, 1936, pages 16-18. History of the use of Fe and steel as structural members in buildings. Cast-Fe beams and columns were first used in an English building in 1801. Wrought-Fe joist section was rolled in Paris in 1849. First wrought-Fe joists rolled in England were in 1860. First steel joists were rolled in England in 1885. Rolled steel sections were available in the U. S. in 1884. Home Life Insurance Building in Chicago, built in 1884-1885, was first modern building to use structural steel. It was started with wrought-Fe beams, and before completion, bessemer steel beams were used. Open-hearth steel shapes were rolled in 1891. Wrought-Fe shapes were discontinued in 1894. MS (15b)

Copper and Old Heating Materials (Le Cuivre et l'ancien Material de Chauffage) G. DUBOIS. *Cuivre et Laiton,* Vol. 9, Mar. 15, 1936, pages 103-105. A historical review of pipe lines, steam producers, heating plants in which Cu was used almost exclusively. Ha (15b)

MANUFACTURERS' LITERATURE

Colmonoy

Bulletin No. 50 which is devoted to the wear-resistant, corrosion-resistant and heat-resistant alloys and overlay metals is published by the Colmonoy Co., Los Nietos, Calif. (680)

Refractories

Pyro Steel fire brick is the subject of a pamphlet which contains a typical analysis of the material, as well as information as to its characteristics, among which are high fusion point, slow vitrification and low permanent shrinkage. Pyro Clay Products Co., Oak Hill, O. (681)

Amaloy Prevents Corrosion

Amaloy is a hot dipping process which coats the base metal with a single solid solution of lead. The manufacturer claims that it adheres and forms a permanent protective coating for forged, drawn or rolled steel, brass and copper. American Machine & Foundry Co., New York, N. Y. (682)

Permite Six Foot Cast Bronze Bars

An attractive booklet states that these bars assure a product identical in physical and wear resisting qualities with the finest individual castings. Joseph T. Ryerson and Son, Inc., Chicago, Ill. (683)

Properties of OFHC Copper

An attractive booklet contains reprints of three papers relating to the above subject. Photographs, diagrams and photomicrographs are used to illustrate them. United States Metals Refining Co., New York, N. Y. (684)

Coreless Induction Furnace

A colorful leaflet contains an explanation of the principle of operation and advantages to be obtained from the use of the Ajax-Northrup electric furnaces. Ajax Electrothermic Corp., Trenton, N. J. (685)

Flame-Otrol

This automatic gas shut off which is simple, positive in operation and operates with split second speed, according to the manufacturer, is the subject of an illustrated pamphlet. Thermo Control Devices, Inc., Chicago, Ill. (686)

Braze-Rite Furnace

This furnace, developed principally for brazing sintered carbide cutting tools, provides for localized heat to be applied only to the portion of the tool to be brazed. The sintered carbide blank to be brazed in place is merely laid onto the shank and after the proper heat has been obtained the blank is firmly pressed onto the shank—all controlled under a hydrogen atmosphere. Illustrated. Firth-Sterling Steel Co., McKeesport, Pa. (687)

Industrial Proportioning

Bulletin No. 1529 states that this company offers a complete line of proportioning equipment and weighing apparatus for granular and liquid materials used in industrial processes. Devices of the following types are furnished: manual operation; manual operation with electrical interlocks to automatically control accuracy of proportioning; semi-automatic operation—consisting of power operated filling and discharge gates for the proportioning equipment; and full automatic proportioning equipment with remote control. Illustrations. Blaw-Knox Co., Pittsburgh, Pa. (688)

Alloy Steels

A colorful folder devoted to these steels lists some of the advantages to be obtained by their use. Bliss & Laughlin, Inc., Harvey, Ill. (689)

Industrial Furnaces

A well-illustrated circular contains data on this company's various types of furnaces. High speed furnaces, car bottom furnaces, galvanizing and tinning furnaces are a few of the types mentioned. Chicago Flexible Shaft Co., Chicago, Ill. (690)

The 92 Elements

A leaflet contains data on the 92 elements relating to X-ray work. St. John X-Ray Service, Inc., Long Island City, N. Y. (691)

The Jetal Process

Simple immersion in an aqueous bath for about 5 minutes colors all grades of common iron or steel a brilliant and uniform jet black. It is claimed it does not alter dimensions of articles and cannot chip, scale, peel or discolor. Alrose Chemical Co., Providence, R. I. (692)

Zinc Alloy Die Castings

A technical booklet tells the story of the development of the "Zamak" alloys. Tables and illustrations. New Jersey Zinc Co., New York, N. Y. (693)

Furnaces

Information concerning Hausfeld modern melting equipment for die casting is featured in an illustrated leaflet. These furnaces are made interchangeable for oil or gas fuel. Campbell-Hausfeld Co., Harrison, O. (694)

Duo Metals

A colorful bulletin discusses the advantages of the Duo process which makes it possible to weld a high alloy steel capable of being forged to any alloy steel. Illustrated. Latrobe Electric Steel Co., Latrobe, Pa. (695)

Spencer Turbo-Compressors

This bulletin which has illustrations of the complete range of sizes of this equipment also contains: "Midget" Turbo for individual mounting, a single-stage line which effects new economies and Gas-Tight Turbos for acid and explosive gases. Spencer-Turbine Company, Hartford, Conn. (696)

Silico-Manganese Spring Steel

Extreme care is taken in processing this steel to avoid imperfections, in rolling to obtain cold-shearing qualities and in controlling the uniformity of the structure to insure both high inherent fatigue resistance and uniform heat treating characteristics, according to the manufacturer. Illustrated. Bethlehem Steel Co., Bethlehem, Pa. (697)

Sand Control in the Foundry

A colorful pamphlet lists the major causes of casting defects and inferiorities and states that they may be avoided by the use of the proper sand control equipment. Illustrated: Harry W. Dietert Co., Detroit, Mich.

Published by the same company: "The Core Maker"—a leaflet and "Deformation and Resilience Accessory for Universal Sand Strength Machine"—looseleaf data sheet. (698)

Chapmanizing

A pamphlet devoted to Chapmanizing, which is a process of hardening low-carbon steel, compares it to nitriding and carburizing. The Chapman Valve Mfg. Co., Indian Orchard, Mass. (699)

Centrifugal Castings

Advantages, analyses of metal—sizes of tubes, application, machining and welding and production facilities of those castings are discussed in an illustrated folder of The Duraloy Co., Pittsburgh, Pa. (700)

High Temperature Insulation

For all types of heated equipment is the subject of an illustrated leaflet issued by Armstrong Cork Products Co., Lancaster, Pa. (701)

Copper Alloy Steel Sheets

In an attractive, illustrated booklet it is claimed that the major attributes of a satisfactory sheet metal—workability, durability and usefulness—characterize this company's steel sheets. Inland Steel Co., Chicago, Ill. (702)

Enduro

Data on the welding of Enduro stainless steels are given in a colorful brochure. Electric arc, gas, spot and projection, seam, flash, atomic hydrogen welding and brazing and silver soldering are features of this discussion. A complete list of products is included. Illustrated. Republic Steel Corp., Massillon, O. (703)

Industrial Dust Control

This book charts the progress made by various types of dust collecting systems to the present time, outlining the advantages that modern dust control brings to industry today. Chapters on: exhaust hoods and piping system; dust collecting equipment; types of collectors in general use in the industrial field; and the operation and maintenance of exhaust systems are featured. Pangborn Corp., Hagerstown, Md. (704)

Electric Thermometers

Bulletin No. 2451 is devoted to the standard types of "Alnor" electric resistance thermometers which, it is claimed, should be used where readings of low temperature values are desired, and where unusual accuracy and distant readings are required. Illustrated. Illinois Testing Laboratories, Inc., Chicago, Ill. (705)

Adjustable Lighting Equipment

An illustrated bulletin dealing with the Herald-Lite type of adjustable lighting fixtures for use in machine shops, plants, drafting rooms, etc. Herrold Co., Richmond Hill, N. Y. (706)

Ferrocarbo

This material containing both silicon and carbon combined in the form of silicon carbide, acts as a graphitizer or softener when added to cast iron. The compound is broken up and the Si and C react vigorously with the Fe with an exothermic effect when the Ferrocarbo comes in contact with the molten Fe. The manufacturer claims that when Ferrocarbo is used with a properly adjusted charge, the fine graphite structure and high strength characteristic of a hard charge are combined with a high degree of machinability. Carborundum Co., Niagara Falls, N. Y. (707)

MANUFACTURERS' LITERATURE

Molybdenum in Iron and Steel

An attractive brochure contains a summary of the part played by molybdenum in ferrous progress, and claims that a great saving in cost with no impairment in quality can be obtained by its use. The Climax Molybdenum Co., New York, N. Y. (754)

Temperature Control Instruments

Bulletin 33 is devoted to instruments for automatic control of temperatures in industrial furnaces. Illustrated. American Electric Furnace Co., Boston, Mass. (755)

Value of Draft Control

Bulletin No. L-125 is devoted to the above subject and points out the proper value of the furnace draft and this company's control which consists of a draft switch, a damper motor and a manual station. Illustrated. Shallcross Controls, Inc., Milwaukee, Wis. (756)

Heat Exchanger

Bulletin No. 173 describes the Duriron heat exchanger which is available in the company's corrosion-resisting alloys—Duriron, Durichlor, Durimet, Durco Alloy Steel and Alcumite. Illustrated. Duriron Co., Dayton, O. (757)

Mallory Elkon

Looseleaf catalog containing engineering data with descriptions, illustrations and recommendations for the selection of electrical contacts for all types of service. P. R. Mallory & Co., Inc., Indianapolis, Ind. (758)

Spectrometric Equipment

Catalog D-221 is devoted to the above equipment. Basic theory and design are described as well as the various types of instruments. Illustrated. Bausch & Lomb Optical Co., Rochester, N. Y. (759)

Granite City HS Grades 1 and 2

Information concerning the Granite City manganese high tensile steels can be obtained from the Granite City Steel Co., Granite City, Ill. (760)

Phosphor Bronze

A leaflet lists the sizes in which the company's twelve-inch stock bushing bars are now offered. The Phosphor-Bronze Smelting Co., Philadelphia, Pa. (761)

Wheelabrator Tum-Blast Cleaner

This cleaner, which it is claimed sets the highest standard of efficiency ever attained in an abrasive cleaning machine is a combination of the Tum-Blast Cleaner and the Wheelabrator. Book 111 is devoted to it. American Foundry Equipment Co., Mishawaka, Ind. (762)

Industrial Furnaces

This catalog describes, illustrates and gives specifications for furnaces suitable for various applications. Mahr Manufacturing Co., Minneapolis, Minn. (763)

Research Puts the Diatom to Work

This booklet discusses the history of the diatom from which Celite is made. The four main industrial services of Celite: high temperature insulation, a filter aid, mineral filler and workability agent in concrete are described. Illustrated. Johns-Manville, New York, N. Y. (764)

Inhibitor

Grasselli 3 inhibitor for efficient, economical pickling is the subject of a booklet of The Grasselli Chemical Co., Inc., Cleveland, O. (765)

A. W. 70-90

This bulletin describes the new high-strength "70-90" steel in sheets and plates. An article on the engineering aspect of high-strength sheet steels is included. Alan Wood Steel Co., Conshohocken, Pa. (766)

Dolomite Refractories

This interesting pamphlet presents the case of Clinkered vs. Calcined Dolomite in the basic open-hearth steel furnace. Basic-Dolomite, Inc., Cleveland, O. (767)

Controlled Grain Anodes

Seymour Nickel Anodes are homogeneous in grain structure, according to this bulletin. The various available shapes are illustrated and some useful data are given. The Seymour Manufacturing Co., Seymour, Conn. (768)

Welding Rods

Hard-facing welding rods Nos. 459 and 217 are the subjects of an illustrated brochure. Hard surfacing can be done with these rods, either electrically or by the oxy-acetylene process to the great majority of ferrous welding parts. American Manganese Steel Co., Chicago Heights, Ill. (769)

Polishing Machines

A portable model and a floor model of these new metallographic machines are described and illustrated in a pamphlet from Eberbach & Son Co., Inc., Ann Arbor, Mich. (770)

Electromet Review

This publication, whose purpose is to brings "News and Views of Alloy Steels and Irons" to the reader, contains interesting items. Electro Metallurgical Co., New York, N. Y. (771)

Modern Metal Treatment

A colorful pamphlet lists the R & H chemicals available for heat-treating, electroplating and for cleaning metals. E. I. du Pont de Nemours & Co., Inc., Wilmington, Del. (772)

Heat and Corrosion Resistant Alloys Heated By Gas

Bulletin C1-A illustrates a number of complex castings made from Q-Alloys which are recommended for pipe fittings, furnace parts, etc. General Alloys Co., South Boston, Mass. (773)

Sicromo Steel

High temperature data sheets containing full information on this steel have been issued by The Timken Steel & Tube Co., Canton, O. (774)

Centrifugal Castings

Bulletin C-2 is devoted to these castings which are available in the same analyses as the stationary-cast range of heat and corrosion resistant alloys which they supplement. Michigan Steel Casting Co., Detroit, Mich. (775)

Metallurgy of Wire Manufacture

This paper contains valuable and interesting data and was presented by H. W. Graham, general metallurgist of Jones & Laughlin Steel Corp., Pittsburgh, Pa. (776)

Weatherproof Line Wire

Publication GEA-2103 gives information on a new wire with varnished cambric and a weatherproof braid treated with U.R.C. compound. General Electric Co., Schenectady, N. Y. (777)

Bearing Security

This leaflet lists the four essentials of a bearing metal and claims that Ajax Bull Bearing alloy embodies them. Ajax Metal Co., Philadelphia, Pa. (778)

Rocking Furnace

Type G-M is a small-scale indirect arc electric furnace designed for iron, steel, brass, copper and nickel alloy. The furnace is illustrated and specifications are included in a leaflet which has been prepared by the Detroit Electric Furnace Co., Detroit, Mich. (779)

Cutting Oils

A leaflet is devoted to the EFHCut series of oils. It is claimed that this series represents the best straight cutting oils obtainable, at a price which meets and beats competition. E. F. Houghton & Co., Philadelphia, Pa. (780)

Vanadium Facts

Another issue of this publication contains accounts of progress and performance in the field of alloy steels. Vanadium Corp. of America, New York, N. Y. (781)

Flex-Arc Rays

Data bulletins containing information on arc welding are published by the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa. (782)

Sixteen Sins of the Cleaning Room

Are listed in a circular for convenience in checking on cleaning rooms. Great Lakes Foundry Sand Co., Detroit, Mich. (783)

Refractory Cement

Bulletin No. 317, describes Q-Chrome neutral-base refractory cement which was designed for severe-service duty. Quigley Company, Inc., New York, N. Y. (784)

Meehanite Metal

A specification chart of recommended grades for various service requirements has been issued by the Meehanite Metal Corp., Pittsburgh, Pa. (785)

Arc Welding

A book "Automatic Arc Welding by the Electronic Tornado" gives a full explanation of this system of automatic carbon arc welding. Lincoln Electric Co., Cleveland, O. (786)

Centrifugal Compressors

Bulletin 386 is devoted to this company's Design 9 Compressors. Illustrated. B. F. Sturtevant Co., Boston, Mass. (787)

Dowmetal Data Book

A new edition of this book, containing especially significant accomplishments since the last data book, in the sections Available Forms and Shop Practice, has been published by The Dow Chemical Co., Midland, Mich. (788)

CURRENT NEWS ITEMS

A New Film—"Super-Refractories Through the Microscope"

A very unique motion picture film entitled "Super-Refractories through the Microscope" has been developed by the research laboratories of The Carborundum Co. and is available for showing before interested technical societies.

The first part of the film was made by the kodachrome process and shows the structure of various refractory materials as they are revolved on the stage of the polarizing microscope. The second part of the film was made by means of the newly developed thermal microscope and gives a graphic demonstration of the actual behavior of various types of refractories under severe operating conditions.

The first public showing of the film was given at the convention of the American Ceramic Society in March, 1936, and the comments of the large audience were to the effect that not only were the pictures themselves of great interest but they were concrete evidence of the development of a new laboratory technique that was a worthwhile contribution to the interests of manufacturers and consumers of refractories. Interested societies can arrange for showings through the refractory division of The Carborundum Co., Perth Amboy, N. J.

Testing Society's New Officers

At the annual meeting at Atlantic City of the A.S.T.M. in June the following new officers for the ensuing year were elected: President (1 yr.), A. C. Fieldner, chief engineer, experiment station division, U. S. Bureau of Mines, Washington; vice-president (2 yrs.), T. G. Delbridge, manager, research and development department, Atlantic Refining Co., Philadelphia; members of the executive committee (2 yrs.), O. U. Cook, assistant manager, department of metallurgy, inspection and research, Tennessee Coal, Iron & Railroad Co., Birmingham; H. F. Gonnerman, manager, research laboratory, Portland Cement Assn., Chicago; C. S. Reeve, manager, research development, The Barrett Co., Leonia, N. J.; F. E. Richart, research professor of engineering materials, University of Illinois, Urbana, Ill., and F. M. Waring, engineer of tests, Pennsylvania Railroad, Altoona, Pa.

Mr. Fielder, the new president, has been prominent for a number of years in Government departments and has been active in A.S.T.M. committee work. He has been active also in developing standard methods and apparatus for analyzing coal, and the author and co-author of many scientific and technical papers. The honorary degree of Doctor of Science was recently awarded to him by the University of Alabama.

National Founders Assn. Has Consulting Foundry Engineer

The National Founders Association announces the engagement of Gottfrid Olson as consulting foundry engineer. Mr. Olson served his apprenticeship in Sweden, and has worked in the United States some 20 years as molder, foreman and superintendent. He is a graduate engineer (Swedish Government Technical School), and his early education has been supplemented by special courses in metallurgy and allied subjects at schools in this country.

Mr. Olson's work with the association will cover foundry practice, production problems, equipment, apprenticeship, safety and sanitation. He is thoroughly informed on the dust hazard and practical methods for its control.

Honorary Degree for Dr. Fink

Dr. Colin G. Fink, head of the department of electrochemistry, Columbia University, and secretary of The Electrochemical Society, was recently given the honorary degree of Doctor of Science by Oberlin College, Oberlin, Ohio. The citation reads: "Master of Metals, Servant of Learning, of Industry, and of Art. Benefactor through brilliant Invention." Dr. Fink will be the American guest speaker at the Twelfth Conference of the International Chemical Union in Switzerland in August when his topic will be "The Electro-chemical Protection of Iron and Steel against Corrosion."

New Research Associate Plan at Battelle

The Trustees of Battelle Memorial Institute have announced a new plan to extend the scope and utility of the educational features of the institute's basic program of scientific research. Since its inception, the policy of Battelle has been to combine a program of fundamental research of general interest to industry with the applied research which it has carried on for individual companies and associations under its plan of sponsored research.

A new Division of Research Associates has been established to supplement the work in fundamental science of the regular technical staff. The purpose of this new division is to offer intensive training in practical research to the best of the younger workers in selected branches of chemistry, metallurgy, fuels and ceramics. Appointments as research associate will be made for one year's duration and may be extended for a second year. A research associate will be expected to devote his entire time to a research problem approved by the director and supervised by members of the staff. The results of these researches will be published in order to contribute information that will be useful to science and industry.

Appointments as research associate are open to graduates of any accredited university or college, but preference will be shown to men who have demonstrated a marked aptitude for scientific research in their industrial experience or through one or more year's graduate study. The appointment will carry an annual salary of from $1200 to $1800 depending on the training and experience of the individual. Four appointments as "Battelle Research Associate" will be made for the year 1936-1937. Applications may be obtained from the director, Battelle Memorial Institute, Columbus, Ohio.

H. C. Mann Awarded Dudley Medal

The Charles B. Dudley Medal, awarded annually by the A.S.T.M., was bestowed this year on H. C. Mann, senior materials engineer, ordnance department, U. S. Government, Watertown Arsenal, at the annual convention in June at Atlantic City. This medal commemorates the name of the Society's first president, 1902-1909, and is awarded to the author of the paper presented at the previous annual meeting which is of outstanding merit and which constitutes an original contribution on research in engineerng materials.

The Mann's paper was entitled "The Relation Between the Tension Static and Dynamic Tests" and presents data and conclusions from an investigation which led to the discovery of a correlation between static and dynamic tests.

The medalist was educated at Worcester Polytechnic Institute and Boston University and has been at Watertown Arsenal since 1916.

C. E. Sims Joins Battelle

Clyde E. Williams, director, Battelle Memorial Institute, Columbus, Ohio, has announced the appointment of C. E. Sims, as research metallurgist at Battelle. Mr. Sims, formerly assistant director of research for the American Steel Foundries, Indiana Harbor, has had an exceptionally wide experience in steel foundry practice. He is the author of numerous technical papers and with G. A. Lilliequist was awarded the Robert W. Hunt prize by the American Institute of Mining and Metallurgical Engineers in 1933 for the paper, "Inclusions, Their Effect, Solubility and Control in Cast Steel."

H. A. Schwartz Honored

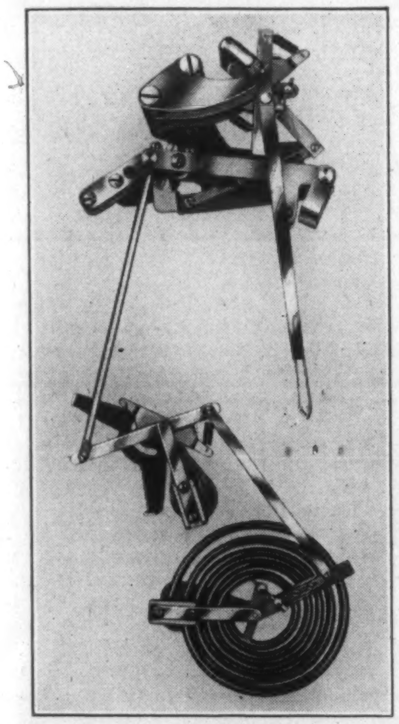
Harry A. Schwartz, National Malleable and Steel Castings Co., Cleveland, was awarded the honorary degree of Doctor of Science by Case School of Applied Science of that city at its 52nd Commercement in June. He also delivered the annual Sigma Xi lecture before the Case chapter when he discussed "Our Debt to Josiah Willard Gibbs."

NEW EQUIPMENT AND MATERIALS

Automatic Pressure Compensator

In measuring the flows of compressible fluids such as steam, air and gas, variations in the static pressure of the flow directly influence the flow reading. To prevent errors from this source, The Foxboro Co., Foxboro, Mass., has developed the "Automatic Pressure Compensator" for Foxboro flow meters.

The mechanism is merely a simple spiral pressure tube connected to a lever. As the line pressure changes, the spiral adjusts the multiplication of the linkage between the float and pen arm. This is not an additive correction but a percentage correction; the linear amount of correction differs at different points of the chart and is calibrated to fit the flow formula of the meter. Thus a continuous, instantaneous and accurate compensation for pressure changes is obtained automatically. The compensator is sensitive to, and will correct, the position of the flow pen for a change in pressure as small as 1-10 of 1 per cent.



At zero flow, pressure changes do not affect the position of the flow pen; at all other points on the chart the shift in pen position is just sufficient to compensate for the effect of this factor in the flow formula. On square-root flow scale meters the pen position is varied proportionately to the change in absolute pressure; on uniform flow scale meters, pen position is varied proportionately to the square root of change in absolute pressure. Should maximum flow and maximum pressure occur simultaneously, the pen will not travel beyond the upper chart limit.

If at any time a pressure-compensating meter is changed over to a service where compensation is not required, the meter is easily adapted to the new service. By attaching one screw on the compensator to the mounting post in the instrument, the compensator becomes inoperative and the differential calibration is that of a non-compensating meter. The Automatic Pressure Compensator does not affect the inclusion of pens for recording pressure or temperature.

An Insulated Electrode Holder

At least 90 per cent of the flashes that welders get are caused by conatcting the ordinary bare type electrode holder with grounded parts. To eliminate such flashes, to provide a maximum degree of safety for the operator and protection for the work and to provide longer and more economical holder service, the Jackson Electrode Holder Co., 6553 Woodward Ave., Detroit, is introducing a new model embodying radical improvements in design.

The new holder, like previous Jackson holders, is completely insulated, air circulation being provided between insulation and metal to achive coolness. In spite of the insulation, total weight of the holder is about that of bare type holders of comparable capacity. A special copper alloy has been adopted for the structural parts of the holder, combining strength with adequate conductivity.

But as the jaws of any holder are the parts first to burn out, this new holder is provided with replaceable jaws of "Mallory 3 Metal," a copper alloy that is already widely used for spot welding tips, flash welding dies and seam welding wheels. It combines the tensile and elastic properties of structural steel with the high electrical conductivity and corrosion resistance of pure copper. This jaw construction has unusually long life and, when jaws ultimately do become worn, replacement is simple, easy and economical, adding indefinitely to the life of the holder.

Armco Stabilized Steel

Full commercial production of "Armco Stabilized Steel" in cold rolled sheets and strip has been announced by the American Rolling Mill Co., Middleton, Ohio.

Stabilized steel is offered by the company as uniform, deep-drawing and non-aging cold rolled steel with all stretcher strain permanently eliminated in the tempered condition. It retains indefinitely all of the properties of temper-rolled steel, making prefabrication treatments unnecessary, regardless of the length of time the metal has been in stock.

Unlike ordinary mild steels for deep drawing purposes, the new metal has no sharp yield point in the temper rolled condition. It is superior in resistance to cracking in some very severe drawing operations, and it will retain its initial excellent drawing properties indefinitely, the company claims.

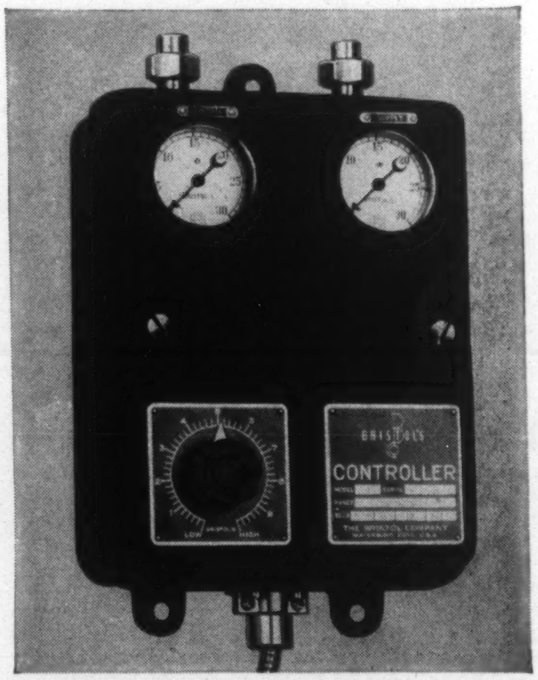
In the general run of mild steel sheets, a sharp yield point develops within a comparatively short time after cold rolling, depending upon the aging temperatures to which they are subjected. It has been found that at 212 deg. F., the "yield point elongation" increases continuously and reaches a maximum after about two weeks at this temperature. The same changes occur at room temperature, but require days instead of minutes for their consumation.

Manufacturers of products in which high finish, deep drawing steel sheets are used have realized that aging in their plants has aggravated breakage and stretcher straining difficulties. Many users of drawing steel will be greatly interested in this development.

Pneumatic Type Temperature Controller

The Bristol Co., Waterbury, Conn., announces a new pneumatic-type controller for temperature, pressure and liquid level. Known as the "Model 90 Controller," this instrument has been developed to take care of the many requirements for automatic temperature and pressure control that do not warrant a chart record of the controlled temperature or pressure, and also, for applications where recording instruments already are in use. The Model 90 is a small, compact instrument of simple construction, which embodies the latest developments in automatic control. The outstanding feature of this controller is its precision measuring element.

The Model 90 Controller is equipped with a wide-range sensitivity adjustment. It can be changed from direct to reverse acting, or vice versa, by the user without additional parts. The case is moisture, fume, and dust-proof and is offered in two forms,—for wall and for flush panel mounting.

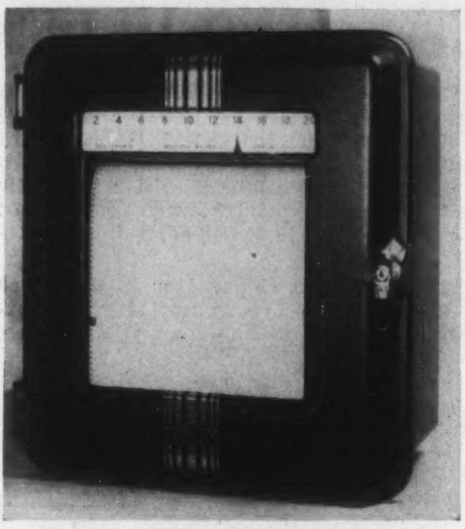


"Smootharc" Welding Electrodes

An entirely new line of coated rods for D. C. welding is now being made and sold through the Harnischfeger Corp. of Milwaukee, manufacturers of P&H-Hansen arc welding equipment. The present line includes five different types with both high and low rates of fluidity for various types of work in welding in flat, vertical or overhead positions and with ferrous and nonferrous metals. Service tests show tensile strength of welds from 55,000 to 75,000 lbs. per sq. in. with various types of rods ranging from 3-32 to ⅜ in. in size. "Smootharc" electrodes are designed primarily to speed up welding operations with a smoother, more easily handled arc and to reduce spatter losses. The new line is described in a new bulletin, No. R-1.

The Silver Anniversary Micromax

The "Silver Anniversary" Micromax recorder, latest and most serviceable of their long line of industrial recording machines, has just been announced by Leeds & Northrup Co., 4934 Stenton Ave., Philadelphia. Marking the 25th year since this concern originated the recording potentiometer pyrometer, this Micromax not only provides in the one instrument all combinations of indicating, recording, signalling and controlling, but provides these functions in ways unique to this model. Measurements are presented most conveniently; a bold scale and pointer shows the condition at the moment, and a clear record on ten visible inches of strip-chart shows it for the past several hours. On controllers, a second pointer shows control setting. Multipoint records may be in blue or in multi-color.



In this Micromax, control and signal contacts operate undisturbed by air currents when the door is opened, even when the chart is changed, or the pen refilled. Pen holds seven-week ink supply. An ingenious double frame makes all parts of the mechanism strikingly accessible, and enables the user to replace the chart without effect on other parts of the recorder.

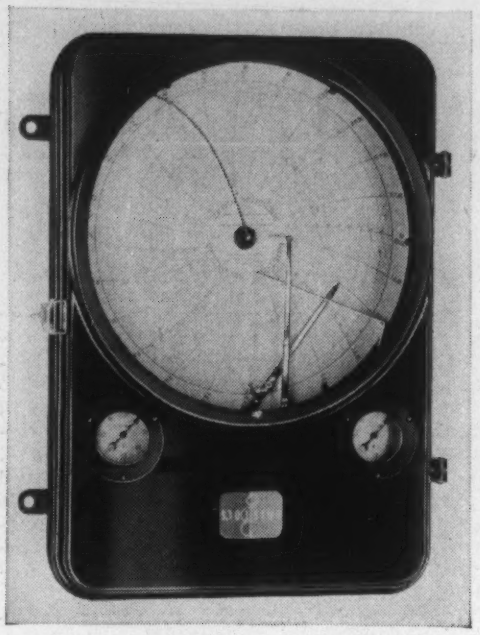
Standard Micromax assemblies assure reliability for the vital operations of measuring, detecting, balancing and control. These assemblies have been improved wherever possible; contacts are heavier, and certain other component parts are new. The machine thus makes available all that is tried and proven in its field; it abandons that which is obsolete and adds new features that make the instrument reliably equal to the needs of modern industry.

New Recorder-Controller with Wide-Range Sensitivity Adjustment

The Bristol Co.. Waterbury, Conn., announces a new series of pneumatic-type controllers known as "Ampliset Free-Vane Controllers." These instruments are now available for automatically controlling temperature, time-temperature, flow, liquid level pressure, time-pressure, and humidity. The Ampliset principle has also been combined with the Metameter, a system of telemetering, recently announced by this company, for the remote control of steam pressure and gas pressure. Bristol's Ampliset Controllers operate on the basic free-vane principle employed by the Bristol company for many years and widely used in industry.

In the Ampliset controller certain features of field adjustability have been added to the time-proved free-vane system, whereby its sensitivity can be changed by means of a small screw driver to exactly fit the lag peculiarities of the process on which it it used. The Ampliset Free-Vane Controller has great versatility. It enables the user to readily adapt it to meet conditions not readily anticipated.

Since the free-vane system is used, which requires practically no power from the measuring element to operate controlling mechanism, the chart record is always accurate. The sensitivity or throttling range of the instrument can be changed without removing the chart or chart dial. It can be changed without, in any way, disturbing the operation of the controller or upsetting the operation or equilibrium of the process. By the same adjustment that regulates the sensitivity of the Ampliset Controller, the instrument can be changed from direct-acting to reverse-acting or vice versa. This change is made by simply turning the scale on the adjustment past the zero point.



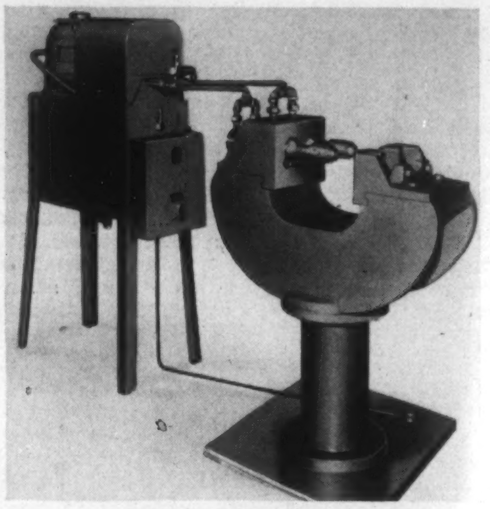
An Industrial Rheostat

The Cooley Electric Furnace Co., of Indianapolis, Ind., announces a new type of industrial rheostat. The rheostat frame is made of cast iron into which is mounted an annular block of refractory material, the same as used in the manufacture of Doreco heating elements. A closely wound resistor coil is embedded in this material. This new and unique material is characterized by the unusual combination of two properties: High dielectric strength and high thermal conductivity. A metal graphite button makes contact with the coil under spring pressure, and affords virtually stepless control of the current within approximately ½ of 1 per cent. The rheostat is simple and rugged and has extraordinary ability to sustain overloads.

New Stationary Riveter

Designed especially for an assembly operation on axle housings, the Hannifin "Hy-Power" hydraulic riveting machine, produced by the Hannifin Mfg. Co., 621 So. Kolmar Ave., Chicago, has duplex hydraulic rams actuated from a new type hydraulic pressure generator unit equipped with automatic electrically operated control valves. A special work holding fixture makes handling extremely simple. Control is by a single foot-switch button, which may be located at any convenient point.

Touching the push button control actuates the hydraulic pump unit and automatic valves, the riveter cycle being completed automatically. The hydraulic ram cycle includes: 1. Rapid advance stroke at moderate pressure, until the die touches the rivet, 2. Automatic high pressure to head the rivet, 3. Reversal at peak pressure, 4. Rapid return stroke to starting position, 5. Oil pump idles at zero pressure between cycles. The riveter ram develops 35,000 lbs. pressure, ample for heading ⅜-in. cold rivets. Equal pressure is applied to head both rivets, regardless of rivet length. The hydraulic pressure generator unit, with automatic valves and control, is driven by a 2-hp. motor and occupies less than 4 sq. ft. of floor space.



This duplex riveting machine is one of several types of high speed units developed for individual production riveting requirements. Other models of Hannifin hydraulic riveters are available in both portable and stationary types and for heading either larger or smaller rivets. The "Hy-Power" hydraulic riveter features of automatic high speed operation, simplified handling, and push button control are exclusive Hannifin developments, and are embodied in the several types of portable and stationary units recently developed.

New Rods for Light Gage Welding Operations

"Thinweld," a specially-coated electrode for arc welding light gage sheet metal, is now offered in 1-16, 3-32 and ⅛ in. sizes by The Hobart Brothers Co., Troy, Ohio. They report that it is in great demand since the introduction of their new 75 and 100 ampere "Simplified" arc welding machines. Among its light welding applications are auto body and fender work; fabrication of heating and air conditioning cabinets, ducts, etc. It is said that some operators have successfully arc welded metal as light as 24 and even 26 gage with the new Hobart models and "Thinweld."

The Core Maker

A new device, called "The Core Maker," has been developed by the Harry W. Dietert Co., Detroit. It is described as the economical way to make cores from unmounted boxes. It will handle all core boxes that are hand stripped.

The Core Maker consists of these major parts—a cast iron base on which is mounted a cast iron table and a vertical plate which is vibrated with either an electric or air vibrator. By a patented connection the vibration does not reach the table on which the cores are stripped. An easily movable vertical guide is mounted on the vertical plate.

The core box may be rammed by hand or by a core blower and then turned over on a core plate, resting on the table of the Core Maker. The core box is pushed against the vertical plate and vertical guide. The vibrator is started by pressing a knee switch. The vertical plate imparts vibration to the core box, which is lifted by hand, using the guide to obtain a perfect lift. Any square cornered metal or wooden core box of single or gang type may be used.

New Flux for Soldering of Aluminum, Cast Iron, etc.

Of interest to solder and flux users is the new flux developed by the Alumaweld Co. of America, 2442 South Park Way, Chicago. This new flux, used in conjunction with a special, high tensile strength solder, is said to do a job heretofore considered impossible.

With "Alumaweld Flux" it is now possible to make high strength, permanent repairs on joints of any metal. It is claimed to make soldering twice as easy because Alumaweld solder and flux is applied with an ordinary soldering iron or blow torch. The soldering job is done at a low temperature but has the advantage of requiring high temperatures to melt it a second time. It works equally well on aluminum, stainles ssteel, die cast pot metal, cast iron, copper, brass, etc., which makes it easy to join any two different metals if desired.

Alumaweld Flux works equally well with any type of solder, but when greater tensile strength is desired, the use of Alumaweld solder is recommended. Alumaweld solder has a tensile strength of 12,000 lbs. which is ten times that of ordinary solder. The finished joint can be worked or machined and takes a polish over which chromium or any other plating can be applied.

Ingot Molds by New Process

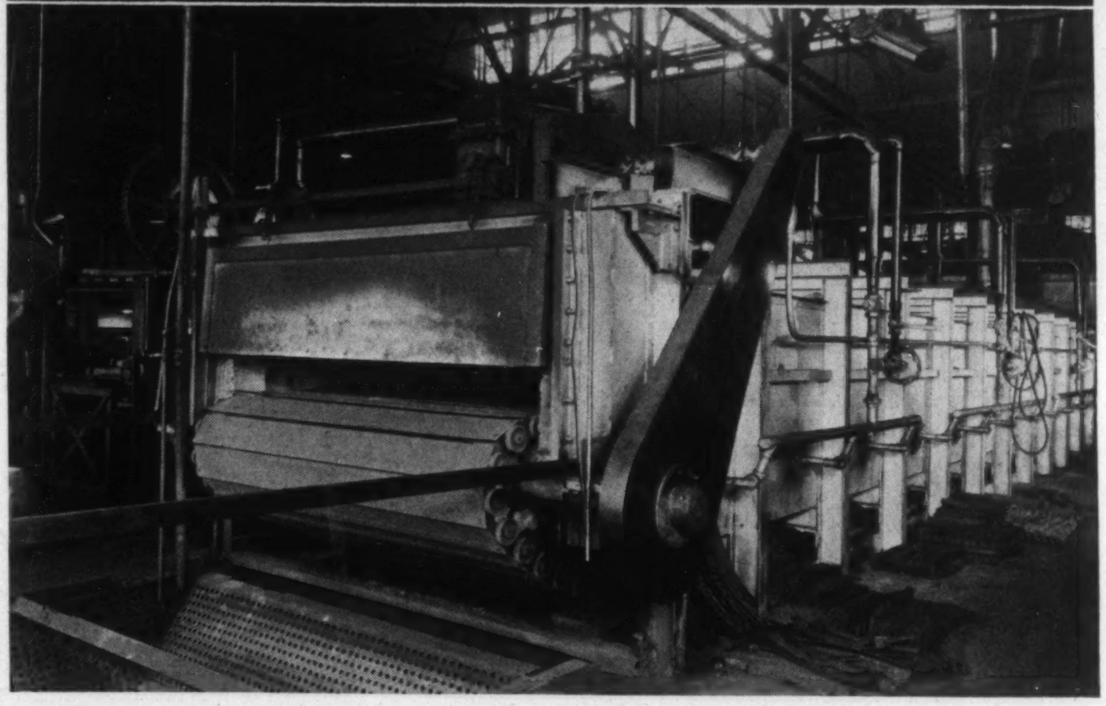
Vulcan Mold & Iron Co., Latrobe, Pa., following considerable experimentation and tests, is in process of changing over plant equipment to manufacture its ingot molds by an improved process new to the foundry industry.

The company has secured the United States license to make ingot molds by the cement-bonded sand process known as the "Randupson" process. It is covered by the Durand patents, which are held by the French Societe D'Electro-Chimie D'Electro-Metallurgie et des Acieries Electriques D'Ugine.

Developed especially to remove factors productive of surface defects in the casting, and to promote greater accuracy in size and contour, the Randupson process is represented by the Birdsboro Steel Foundry & Machine Co., Birdsboro, Pa., as United States agent for the French compony. For some time, Birdsboro has used the process in its own plant.

The use of the cement-bonded sand process by Vulcan is entailing a complete change-over of its plant facilities, which is being pushed to completion as rapidly as possible. The company expects to be manufacturing its entire output by the new process by mid-July.

DESIGN + INSULATION
= QUALITY PRODUCTION
AND FUEL SAVINGS!



That's why **HOLCROFT & CO.** *build this straight-draw furnace with* **ARMSTRONG'S BRICK**

DESIGNED for a large Detroit manufacturer, the Holcroft gas-fired furnace shown above permits accurate temperature control in making of spring . . . insures uniform quality and a minimum of heating loss. The entire furnace area is constructed of Armstrong's N-20 Insulating Brick laid in 9" thickness and faced with a refractory cement.

Leading furnace designers and plant supervisors standardize on Armstrong's High Temperature Products for successful operating results. In addition to N-20 Insulating Brick, the Armstrong Line includes N-16 Insulating Brick and A-25 Insulating Brick (for temperatures up to 1600° and 2500° F., respectively, behind the refractory), EF-22 Insulating Fire Brick and EF-26 Insulating Fire Brick (for direct exposure). We'll be glad to send samples and complete data on any or all of these brick. Write Armstrong Cork Products Company, Building Materials Division, 982 Concord Street, Lancaster, Pennsylvania.

1. ORE CONCENTRATION

JOHN ATTWOOD, SECTION EDITOR

Ore Dressing of Siegerland Copper Deposits (Die Aufbereitung der Siegerländer Kupfererze) H. GLEICHMANN. *Metall und Erz,* Vol. 33, Apr. 1936, pages 193-201. The mineralogic and physico-chemical bases of C ore dressing are discussed. Dry and wet electromagnetic separation methods as well as flotation processes are used. Noble metal concentration and chlorinating-leaching and roasting are described. FPP (1)

Mining in the Rhineland (Untersuchungsarbeiten im rheinischen Erzbergbau) B. ECKERT. *Metall und Erz,* Vol. 33, Jan. 1936, pages 18-21. The location, deposit characteristics, and probable future yield of several ore deposits in the German Rhineland are discussed. FPP (1)

■ 1e. Amalgamation, Cyanidation & Leaching ■

Sulphuric Acid Leaching of Washington Clays for the Production of Alumina and Aluminum Metal. H. C. PARKMAN. *State College of Washington, Metallurgical Research Laboratory,* Bulletin E, Aug. 1, 1935, 51 pages. Al_2O_3 may be extracted from Freeman clay by leaching with 50% H_2SO_4. Roasting is detrimental. Roasting clay with concentrated H_2SO_4 is an efficient method of sulphating the Al_2O_3. The Al_2O_3 produced by evaporating and calcining the $Al_2(SO_4)_3$ solutions formed by leaching acid-roasted Wenatchee clay contained 0.31% Fe, too much for Al electrolytic cells. Crystallization of $Al_2(SO_4)_3$ from the impure leach solution would give a product of sufficient purity for the Al industry. It may be advisable to form alum to get crystals hard enough to be washed free from Fe. The cost of H_2SO_4 extraction of Al_2O_3 is comparable with costs of the Bayer process. AHE (1e)

The Production of Electrolytic Zinc and Vanadic Oxide at Broken Hill, Northern Rhodesia. O. A. E. JACKSON. *Journal Chemical, Metallurgical & Mining Society of South Africa,* Vol. 36, Jan. 1936, pages 173-183; (abstract) *Chemical Trade Journal & Chemical Engineer,* Vol. 98, Mar. 27, 1936, page 262. A mills-Packard plant produces 40 tons of H_2SO_4 daily. Dry ore, containing 25% Zn, is leased without preliminary roasting or concentration. Large amounts of SiO_2 (20 g./l.) are dissolved. Phosphates and vanadates of Fe are precipitated along with SiO_2. The filtrate must be further purified. Ni is very injurious to Zn electrolysis; it is removed by addition of As, Cu and Zn dust. Cl causes dissolution of the Pb anode; it is precipitated by Ag_2SO_4. Cd is removed by Zn dust. The cooled solution is electrolyzed to give a product containing 99.9764% Zn. A 4% V_2O_5 ore is tabled. The 16% concentrate is shipped: the 7% middling is leached, first with very weak acid to remove hemimorphite, then with strong acid to extract V. Neutralization of free acidity with dross (pH 3.00) followed by soda ash additions (pH 5.00) precipitates Cu as a vanadate. The filtrate is acidified and heated in Pb-lined tanks whereby 95% of the H_3VO_4 is precipitated to give a product analyzing V_2O_5 93.5, Cu 0.02, P_2O_5 0.01, ZnO 3.5, Fe_2O_3 1.5, SiO_2 0.2 and other oxides 1.27%. MS + AHE (1e)

The Dissolution of Some Metals in a Solution of Potassium Cyanide. R. HAY. *Journal Royal Technical College,* Vol. 3, Jan. 1936, pages 576-586. The results of experiments on the dissolution of Cu, Al, Ag, Zn, Pb, and Zn-Pb couple in KCN solution are discussed, and it is shown that H is evolved under certain conditions, and the possibility of O functioning as a depolarizer is commented on. The influence of the OH radical upon the pH value of KCN solutions and upon the rate of dissolution of Ag in KCN solution has been determined, and the results have shown that the addition of lime to cyanide solutions does not depend for its beneficial results on the introduction of the OH radical, as the presence of this radical is detrimental to the dissolution of Ag and probably to that of Au. JWD (1e)

The Solubility of Lead Sulfate in Aqueous Solutions of Sulfuric Acid at High Concentrations. H. D. CROCKFORD. *Journal of Physical Chemistry,* Vol. 40, Mar. 1936, pages 303-305. The solubility of Pb-sulphate in various solutions of H_2SO_4 at concentrations over 80% and at 0°, 25°, 35° and 50° C. has been determined. The solid phase at 25°, 35° and 50° C. is always Pb-sulphate. At 0° C. H_2SO_4 and H_2SO_4 monohydrate also exist as solids. EF (1e)

The Cyanidation of Gold-bearing Flotation and Table Concentrate. J. N. BUTLER. *State College of Washington, Metallurgical Research Laboratory,* Bulletin F, Aug. 20, 1935, 48 pages. It is impossible economically to cyanide flotation concentrates which have oxidized between the flotation and cyanide circuits without using some preliminary treatment previous to cyanidation, due to the presence of cyanicides produced by oxidation. A table concentrate is more readily cyanided than a flotation concentrate even though both have stood in air for equal times. A water wash before cyanidation is beneficial; a dilute H_2SO_4 wash is better. Roasting to a dead roast is helpful if temperature conditions are very closely controlled and if Pb is less than 1%. The principles and procedures of cyanidation are reviewed. AHE (1e)

Precipitation of Rare Earths and Thorium with Magnesium Bisulphite. G. P. ALEKSANDROV & YA. P. GOKHSHTEIN. *Redkie Metallui,* Vol. 4, Nov.-Dec. 1935, pages 27-31. In Russian. Th and the rare earths were recovered from minerals by treatment with H_2SO_4 or by chloridization at 600°-700° C., followed by extraction with water. They were then precipitated with $Mg(HSO_3)_2$. From 96-100% of the Th and 80-100% of the rare earths were recovered. HWR (1e)

Milling Practice for Small Gold Mines. C. S. PARSONS. *Transactions Canadian Institute of Mining & Metallurgy,* 1936 (in *Canadian Mining & Metallurgical Bulletin,* No. 286, Feb.), pages 49-51. Discussion. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 109L/10. AHE (1e)

2. ORE REDUCTION

A. H. EMERY, SECTION EDITOR

Some Physical Aspects of Metallurgical Processes (Physikalische Gesichtspunkte bei hüttenmännischen Prozessen) H. WENDEBORN. *Metall und Erz,* Vol. 33, Jan. 1936, pages 45-52; Feb. 1936, pages 70-73. Most smelting operations take place through the action of gases on molten materials partly by chemical and partly by physical mechanisms. Continuous processes examined were those of the shaft-, sintering-, and fines-roasting-furnaces. Discontinuous processes include most melting operations performed in reverberatory and rotating furnaces; with substances with low melting point, heat transfer occurs chiefly by convection, while with higher melting materials heat transfer occurs primarily by conduction. The fusibility of the metal depends on its external form as well as on specific properties such as thermal conductivity and heat content at the melting temperature. Comparison of short and long drum type furnaces shows that substances melting in the lower and middle temperature ranges do so more rapidly in the short than in the long furnace, whereas difficultly fusible materials are more rapidly melted in the long furnace. FPP (2)

■ 2a. Non-Ferrous ■

A Survey of the Aluminum Industry and Its Metallurgical Processes, with Reference to the Utilization of Northwest Clays. R. M. MILLER. *State College of Washington, Metallurgical Research Laboratory,* Bulletin D, July 15, 1935, 71 pages. A review. AHE (2a)

The Rhokana Electrolytic Copper Refinery. ARCHER E. WHEELER & HENRY Y EAGLE. *Bulletin, Institution of Mining & Metallurgy,* No. 379, Apr. 1936, 19 pages. Nkana blister Cu is of exceptional purity with a precious metal content (Au 0.02 and Ag 2.22 oz./ton) too low to justify electrolytic refining simply to recover these values. However, Bi content is too high (0.0093%) to permit making highest quality Cu by fire-refining methods only. The new refinery, consisting of an anode department, an electrolytic tank house, and a furnace refinery, is described. AHE (2a)

■ 2b. Ferrous ■

Influence of Weather Conditions on Blast Furnace Practice (Einfluss der Witterungsverhältnisse auf den Hochofenbetrieb) K. GUTHMANN. *Stahl und Eisen,* Vol. 56, Mar. 5, 1936, pages 293-297. Rainfall causes a decrease in the dust. Composition and heat content of the blast furnace gas changed with the humidity and moisture in the charge. Increased humidity lowered production and raised fuel costs. SE (2b)

The Physical-Chemical Bases of the Mixing of Iron Ores. Part III (Die physikalisch-chemischen Grundlagen der Möllerung von Eisenerzen. Teil III) J. KLÄRDING. *Archiv für das Eisenhüttenwesen,* Vol. 9, Sept. 1935, pages 127-129. In the reduction of mixes of FeO, Al_2O_3, and SiO_2, the sillimanite is the least stable of the possible compounds of these oxides. Al_2O_3 and SiO_2 are slagged by FeO. In the presence of SiO_2 and Al_2O_3, maximum reduction of FeO and easiest slagging of the refractory oxides lies at $3\,CaO \cdot SiO_2 \cdot Al_2O_3$. SE (2b)

Reduction Conditions with Experiments on Prereduced Sinter in a Charcoal Blast Furnace at Sandviken (Undersökningar beträffande reduktionens förlopp samt försök med forreducerad sinter vid Sanvikens masugn nr 3). MARTIN WIBERG. *Jernkontorets Annaler,* Vol. 119, Dec. 1935, pages 499-548. When pig Fe with 1.31% Si and 1.51% Mn was produced from sinter with 55% Fe, the consumption of charcoal was 50 hl. (715 kg. dry charcoal) per 1000 kg. pig Fe. The temperature of the blast was 375° C. and the CO_2-content of the blast-furnace gas 13.4%. The velocity of the gas was highest near the wall of the furnace, where the main part of the ore was passing down. Indirect reduction started at 500° C. Above 700° C., the CO_2-content of the gas was higher than that corresponding to the equilibrium $CO_2 + C = 2CO$. The direct reduction started at 750° C. and reached its highest intensity at 750-1000° C. At 1000-1100° C. the sinter was in the main reduced to Fe sponge. No deposition of C occurred in the upper part of the furnace. Most of the H in the charcoal was driven out between 700 and 900° C. Below 900° C. the content of water vapour in the gas was higher than that corresponding to equilibrium for the water gas reaction. H_2O and CO therefore may react in the upper part of the furnace, forming H_2 and CO_2. The moisture in the gas counteracts the reducing action of H in the upper part of the furnace. During a period of 2 weeks one of the Sandviken furnaces was operated with prereduced sinter with a composition between FeO and Fe_3O_4 (degree of oxidation = 78%). The sinter was reduced in a continuous shaft furnace by means of cold blast-furnace gas, the sinter first being heated to 1000° C. in the upper part of the shaft by burning the gas. The original sinter consisted principally of Fe_2O_3. No metallic Fe was obtained and no deposition of C took place during the reduction. When this prereduced sinter was used in the blast-furnace, the CO_2-content of the gas decreased from 13.5 to 9.4%. This change was greater than would be expected from the decrease of the O content of the charge and an increase in the charcoal consumption of 2.9 hl. (40 kg. dry charcoal) per ton pig Fe was thus obtained. Also in this case there was no deposition of C in the furnace. The reduction did not start until 720° C. At higher temperatures the prereduced sinter was less easily reduced. This was probably because ordinary sinter is easily disintegrated after prereduction at low temperature in the blast-furnace, the reacting surface thus being considerably increased. Sinter which was prereduced at a high temperature in a special furnace remained hard in the blast-furnace. When both kinds of sinter were reduced with charcoal powder in a box, no difference in reducibility was found. HCD (2b)

3. MELTING, REFINING AND CASTING

Questal Bentonite [Bond for Moulding Sand]. J. N. Wilson. *Aluminium & the Non-Ferrous Review,* Vol. 1, Apr. 1936, pages 315-317. Extracted from booklet by Quest Products Ltd., Cheshire. By incorporating "Bentonite," a colloidal bond material, in silica sand, a molding sand having high permeability, high strength both green and dry, and needing the minimum amount of added water, is obtained. JCC (3)

3a. Non-Ferrous

G. L. CRAIG, SECTION EDITOR

The Castability of Aluminum Alloys. Investigations with the Spiral Mold. A. von Zeerleder. *Metal Industry,* London, Vol. 47, Nov. 29, 1935, pages 531-534, 540. The requirements for a suitable casting alloy are indicated. The author then gives, in brief, the history of the study of castability and describes, in general, some of the types of molds that have been used. The method and equipment developed by Portevin and Courty are described in detail. Results of experiments using this method with pure Al, Anticorodal (A.W. 160) with 2% Si, 0.6% Mn and 0.6% Mg, Anticorodal with 5% Si, 0.6% Mn and 0.6% Mg, and Silumin with 13% Si are discussed. Applications of the use of the spiral mold and the effect of the solidification range are considered. 11 references. HBG (3a)

Casting and Shaping (Giessen und Gestalten) O. Summa. *Aluminium,* Vol. 18, Apr. 1936, pages 135-138. In general, wall thickness for sand castings should be, if possible, more than 3 mm., for chill mold castings 3 mm. and for die castings it can be less than 3 mm. Transitions of wall thicknesses should have a radius of 4, 3 and 1 mm. respectively for the same type of castings. Examples illustrate a few very complicated ribbed castings and the arrangement of pattern and mold to obtain a uniformly dense material. Ha (3a)

Foundry Practice for Large Non-Ferrous Castings. M. C. Oldham. *Metal Industry,* London, Vol. 47, Nov. 15, 1935, pages 483-486. The author refers to the diversity and complexity of non-ferrous alloys in any foundry which must deal with a wide range of engineering requirements. He cites Mn-bronzes, various brasses, phosphor-bronzes, gun metals, Al alloys of different types, Si brasses, etc. He comments upon the problem of mixed scrap and states that the real foundry problems deal with metallurgical and associated subjects. Problems considered are temperature control, furnace atmosphere, effect of variations in the freezing range, temperature uniformity in large castings, and molding practice for Mn-bronze castings. A method to avoid entrapment of ZnO in castings is suggested. HBG (3a)

The Solubility of Hydrogen in Molten Aluminium. L. L. Bircumshaw. *Transactions Faraday Society,* Vol. 31, Oct. 1935, pages 1439-1443. The solubility of H_2 in molten Al was determined at 700°, 800°, 900° and 1,000° C. and the volumes (N.T.P.) of gas dissolved were found to be 0.23, 0.89, 1.87, 3.86 cc./100 g. of metal respectively. The "saturated" heat of solution was calculated to be 43,400 cal./g. of gas dissolved. 6 references. PRK (3a)

Metallurgy of Crucible Steel Making (Zur Metallurgie der Tiegelstahlerzeugung) O. Meyer, W. Eilender & A. Walz. *Archiv für das Eisenhüttenwesen,* Vol. 9, Apr. 1936, pages 475-481. The metallurgical reactions in the crucible melting of 0.85% C steel were observed, the reactions of C, Si, Mn, O_2, and N_2 being followed. A vigorous boil improves the quality of the steel, the boil occurring by the reaction of C with SiO_2 of the crucible; there is practically no reduction of Si from the slag. In normal melting an equilibrium between the bath, crucible, and slag should be attained, whereby the slag remains constant in composition. SE (3b)

Influence of Carbon on Steel Making Reactions (Ueber den Einfluss des Kohlenstoffs auf den Ablauf der Stahlerzeugungsverfahren) F. Körber, W. Oelsen, G. Thanheiser & P. Bardenheuer. *Stahl und Eisen,* Vol. 56, Feb. 13, 1936, pages 181-208. A summary report of the extensive studies by the Kaiser-Wilhelm-Institut für Eisenforschung, in 3 parts. I. *The Essentials of Carbon Removal.* The reactions of C in the bath with the oxides in the slag and bath to form CO are discussed. This reaction, resulting in a C drop, is governed by external factors favoring the formation of CO bubbles in the bath, surface effects etc., as well as by the relatively simple chemical equilibria. Under certain conditions (these results were obtained in laboratory crucible melts) an unreactive bath is obtained even in the presence of C and oxides, so that no C drop occurs. CO bubbles generally do not begin to form within the bath or at the contact surface with the molten slag, but only at the contact surface with a solid, such as the walls of the crucible. A vigorous boil does not necessarily signify a high oxide content of the bath; more likely it indicates high reactivity of the C which results in bringing the O_2 content of the bath down to lower values than would be in equilibrium with the oxide content of the slag. II. *Carbon in the Acid Open-Hearth Process.* The changes in composition of the bath and slag of five 30-ton acid open-hearth heats were observed. In all of these a considerable amount of Si was reduced into the bath, C exerting a strong reducing action. Because of this strong reducing action of C, the O_2 in the bath was removed at a faster rate than it could be replenished from the slag or furnace lining to reach the equilibrium value for O_2 in bath vs. oxides in slag. The lower layer of the slag directly in contact with the bath is impoverished in FeO and MnO and enriched in SiO_2, so that this layer becomes very viscous, almost solid. The Si content of the bath rises above the equilibrium value for SiO_2 in the slag, and the reaction between bath and slag is largely inhibited. For this reason the reduction of Si determines the rate of C drop at the end of the heat. III. *Carbon in the Basic Open-Hearth Process.* The changes in composition of the bath and slag of eight 30 and 60-ton basic open-hearth heats were observed, special attention being paid to the reaction between C and O_2. For higher C contents and temperatures these react very rapidly. So long as about 0.2% C is present and this behaves reactively, the O_2 content of the bath is determined by the C content. When the C content falls below this value, however, the O_2 content of the bath is determined by the FeO in the slag. Low concentrations of C or O_2, low temperature, and a viscous slag inhibit the reaction of C with O_2. The Mn content of the bath or the MnO content of the slag govern the FeO content of the slag, and thereby the rate of the C reaction. A high Mn content prevents an undue rise in the O_2 content of a low-C bath. The reduction of Mn out of the slag is a sure sign of a lowering of the O_2 content of the bath by means of C; the more Mn is reduced from the slag, the less need there is for final deoxidation. There is a lively discussion between Schenck and the authors on the following questions among others. Does the partition of O_2 between slag and bath approach equilibrium? Does the rate of C drop always depend on the C and O_2 content of the bath? Does the O_2 content of the bath depend on the FeO in the slag or the C content of the bath? Does a slow or fast rate of C drop give a lower O_2 content of the bath? SE (3b)

Investigation Shows Actual Cupola Melting Loss and Gain. J. A. Lannigan. *Foundry,* Vol. 64, Jan. 1936, pages 34, 72. Describes tests conducted to determine actual cupola melting loss or gain. Each of 7 heats was made up of one class of material only. The C pickup or gain in steel minus total of pig and scrap left a net gain of 1.0%. Fe lost in emlting was as follows:

50% machine cast pig	..........known melting loss	—negligible
25% No. 1 machinery scrap	..........known melting loss	— 0.65
25% steel scrap	....known melting gain (due to C pickup)	— 1.65
	Total gain........	1.00

Great Lakes MOLDING SANDS

Molding Sand, whether Natural or Synthetic, should have a definite texture, flowability, cohesiveness, permeability, refractoriness and durability in order to produce good castings, fast molding, excellent finish, and minimum scrap.

We have sands that meet these six requirements!

Foundry Sand Service

Many of the best known and largest production and jobbing foundries in the country have standardized on sands and rebonding materials recommended by us.

An invitation from you to have one of our staff call to investigate your operation and make suggestions places you under no obligation. Write or wire us today.

Formed Tubes Cast in Gray Iron. *Foundry,* Vol. 64, Jan. 1936, pages 35, 75. Describes the casting of formed tubes for use as electric immersion heaters inside of protective coating of gray Fe by the Cleveland works of Westinghouse Electric & Mfg. Co. Metal straps welded to tubes hold them in place while mold is filling with molten Fe. A metal block serves double purpose of holding all ends of tubes in proper position and forming a chill to protect open end of tubes and metal from shorting tube and resistance wire. Tubes are sandblasted, dipped in Al paint and dried for 30 min. Moisture is removed by heating in oven to 400° F. for an hr. Tubes are set in mold and metal poured quickly. Fe at 2450°-2500° F. gives best results. 8 gates are used. VSP (3b)

Ford Casts Parts of Alloy Iron and Steel. *Foundry,* Vol. 64, Feb. 1936, pages 26-27, 70. Most recent improvements at the plant of Ford Motor Co. are: (1) 36″ water line from power house to rolling mill; (2) Hot strip mill completely equipped; (3) New blooming mill; (4) Cold finishing mill; (5) Ingot stripper; (6) Reconstruction of blast furnace to increase capacity from 600 to 800 tons daily; (7) Modernization of main power house; and (8) Alloy steel casting department in foundry. Although alloy steels of various compositions are used for many automobile engine parts, cast Fe is still the most satisfactory for cylinder blocks. The composition of this Fe is: Total C 3.20-3.40%; Si 1.90 = 2.10%; S 0.10 max.; P 0.25-0.32%; Mn 0.60-0.80%; Cu 0.75%. The analyses of various alloy Fe castings for crankshafts, cylinders, insert rings and valves are tabulated. VSP (3b)

Manufacture and Qualities of Wrought Iron. E. W. KAVANAGH. *Proceedings Southern & Southwestern Railway Club,* Vol. 23, Jan. 1936, pages 8-30. Definition of wrought Fe as made in the puddling process, the chemistry of the latter as represented principally by the reactions (1) $Fe_2O_3 + 3C = 3CO + 2Fe$ and (2) $CO + O = CO_2$ and the treatment of the puddled Fe are described. Ha (3b)

Reactions of Chromium with Acid Slags (Die Reaktionen des Chroms mit sauren Schlacken) F. KÖRBER & W. OELSEN. *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Vol. 17, No. 21, 1935, pages 231-245. The behavior of Cr in solution in the molten Fe against ferrous oxide-manganous oxide-silicates in presence of solid silicic oxide were studied in order to determine the reactions of Cr with basic slags in steel production. It can be stated that the equilibrium conditions of the reactions of Fe, Mn and Si with their oxides are only slightly changed in the presence of Cr in the metal layer and in the slag layer. The slagging of Cr, i.e. the ratio $(\Sigma Cr)_{slag} : Cr_{metal}$ depends largely on the composition of the steel melt and of the silicate slag; this ratio increases strongly with increasing ferrous oxide content of the slag. Higher Mn and Si contents of the steel melts result in a lower ferrous oxide content of the slag and of the melt and in this manner counteract the oxidation of Cr. Compared with Mn and Si, Cr is a very weak reducing agent so that its deoxidizing effect in the deoxidizing of Cr-containing Fe by Mn and Si is low. Cr occurs in acid slags and in the silicate inclusions of Cr steels in part as Cr_2O_3, mainly as CrO as long as slags and inclusions are still liquid. When the slags crystallize the chromous oxide largely disintegrates to chromic oxide and metal. 16 references. Ha (3b)

Simple Facts About Common Steels. J. R. MILLER. *Heat Treating & Forging,* Vol. 22, Mar. 1936, pages 129-131. Discusses deoxidation of steel, inclusions, and making, handling, and heating of ingots, to show their effect on quality of steel. Well melted steel can be very badly injured, and poorly melted steel may be materially improved, according as deoxidizing, teeming, handling, stripping, and soaking are poorly or well done. Steel, well made up to ingot form, is very hard to spoil except by grossly careless stripping, soaking, and rolling. MS (3b)

Heat Losses in the Bessemer Converter. M. PASCHKE & E. PEETZ. *Iron & Coal Trades Review,* Vol. 132, Mar. 13, 1936, pages 487-488. The report of Verein deutscher Eisenhüttenleute in Stahl und Eisen is given in full with curves and charts. Ha (3b)

Steel Castings are Produced in Molds Bonded with Cement. PAT DWYER. *Foundry,* Vol. 63, Dec. 1935, pages 22-24, 60; Vol. 64, Jan. 1936, pages 30-32, 68, 70; Feb. 1936, pages 28-30, 72, 74, 77; Mar. 1936, pages 30-32, 71-72. Describes the Randupson process for making molds for steel castings used by the Birdsboro Steel Foundry & Machine Co. Nearly all classes of castings are made by this process, ranging in wt. from a few lb. to 50 tons. In this method new silica sand is bonded with cement in proportions dependent upon type of casting to be produced. Advantages claimed are that castings conform accurately to size and shape of pattern and no ovens are needed to dry molds. Rods, arbors or other reinforcements are greatly reduced by use of molds and cores from cement bonded sand. The process lends itself readily to construction of cores. Illustrates successive steps in production of a sand-cement core for a bent pipe 11′ long and 22″ inside diam. Concludes with a brief history of the company. VSP (3b)

Used Dry Sand Runner Boxes to Eliminate Dirt in Iron Castings. T. H. BEAULAC. *Foundry,* Vol. 63, Dec. 1935, page 35. Castings for air compressors, oil and gas engines, diesel engines, etc. are cast in dry sand. Consequently molds taken from ovens are very hot, and while green sand runners are built, they become dried out and crumbly. Dry sand runner box is used on castings up to 1 ton. Describes method of procedure. VSP (3b)

Castings Support Steel Cables. W. A. BECK. *Foundry,* Vol. 63, Dec. 1935, pages 32, 74. Briefly describes the casting of cable supports for the Golden Gate Bridge by the Bethlehem Steel Corporation. Plain C steel, melted in open-hearth furnaces, was poured into pit molds arranged for bottom pouring. Each casting was fed by 9 risers. Afterwards castings were annealed to remove internal strains and rough machined. Finishing was done at another plant. Each support consisted of 3 segments bolted together. Combined wt. of each unit was about 150 tons. Maximum metal thickness was 7″. VSP (3b)

Iron Content of Basic-Bessemer Slags for Various Lengths of Blow (Eisengehalt der Thomasschlacke bei verschiedenen Blasezeiten) O. SCHEIBLICH. *Stahl und Eisen,* Vol. 56, Apr. 30, 1936, pages 505-512. Under otherwise comparable conditions increasing the time of the blow did not increase the Fe content of the slag. Variations in the latter were obtained for very short blows, probably because of temperature fluctuations. SE (3b)

Distribution of Phosphorus Between Steel and Slag. E. MAURER & W. BISCHOF. *Metal Progress,* Vol. 29, Jan. 1936, pages 48, 70. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 6L/1. WLC (3b)

High Chromium Alloys—Centrifugal Castings and Tubes. R. J. WILCOX. *Metal Progress,* Vol. 29, Jan. 1936, pages 44-48. Molds are prepared by ramming sand around a pattern carefully centered in a flask and drying it in a vertical position at uniform temperature. Flask containing sand mold is locked in the machine, pouring spout placed and rotation started. Speed of rotation is selected for the thickness and length of casting. Metal to form desired wall is accurately measured and poured into the spinning mold. Concentricity is obtained by accurate centering of pattern and balance of the rotating parts. Uniformity of longitudinal section depends upon fluidity and centrifugal force. It is obtained by length limitation and proper speed selection. Ratio of wall thickness to length is limited by fluidity. These limits for 18-8 and 29-9 stainless are 9′ length with wall of 5/16″ and diam. up to 12″; for the 35-15 type 1/8″ wall is obtainable in longer lengths. Tubes form quickly. Uniform distribution of metal is achieved in approx. 7 sec. and complete solidification in 60-90 sec. for a 9′ tube with 5/16″ wall and 8″ diam. Applications of such tubes are discussed. WLC (3b)

German Open-Hearth Practice with Coke Oven Gas (Betriebsergebnisse deutscher Siemens-Martin-Oefen mit Koksofengasbeheizung) B. VON SOTHEN. *Stahl und Eisen,* Vol. 56, Mar. 12, 1936, pages 321-328; Mar. 19, 1936, pages 351-362. An extensive study of the properties and relative advantages of cokeoven, producer, and mixed gas. 4a. Rolling

RICHARD RIMBACH, SECTION EDITOR

Spreading During Rolling with Varying Rolling Speeds and Steel Compositions (Das Breiten beim Walzen bei verschiedenen Walzgeschwindigkeiten und Stahlzusammensetzungen) A. Spenlé. *Stahl und Eisen,* Vol. 56, May 7, 1936, pages 544-549. Rolling C steels at varying speeds indicated that the rolling speed should be kept within certain limits for the variations in width not to exceed the specification. The addition of various alloying elements tended to increase the departure from the specified width. SE (4a)

Production Supervision in a Billet and Rail Mill (Leistungsüberwachung einer Block- und Schienenstrasse) K. Skroch. *Stahl und Eisen,* Vol. 56, Jan. 2, 1936, pages 10-14. Time studies were made and the soaking pits found to be the bottle-necks. SE (4a)

Some Considerations Influencing Plant Facilities for Strip-sheet Production Under British Conditions. Geo. A. V. Russell. *Iron & Steel Institute,* Advance Copy No. 13, May 1936, 19 pages. The commercial possibilities of wide-strip mills in England are considered. Comparison of British and American conditions lead the author to conclude that smaller productive units are desirable in England. 3 designs of wide-strip mill plants of different capacities and product ranges are shown as being applicable to British conditions. JLG (4a)

A New Strip and Band Steel Rolling Mill (Ein neues Streifen- und Bandstahl-Walzwerk) G. B. Lobkowitz. *Stahl und Eisen,* Vol. 56, May 14, 1936, pages 571-574. A new mill for rolling band and strip steel 15 to 400 mm. wide, 0.8 to 2.75 mm. thick and up to 120 m. long is described. SE (4a)

4b. Forging & Extruding

A. W. DEMMLER, SECTION EDITOR

Forming and Forging in 1935. F. L. Prentiss. *Iron Age,* Vol. 137, Jan. 2, 1936, pages 309-312; Jan. 9, 1936, pages 36-39, 86. Progress in forging industry consisted in improvement in quality and accuracy of product, in development of more efficient equipment, in technical advancement and in lowering of production costs. Sizing to shape on accurate coining presses to reduce machining became more general. Hammer forgings are held to tolerances of 0.008" or less and these are reduced to 0.005" or less on coining presses. Extrusion has become more general particularly for gear forgings. No important advances were made in cold forging. Forging furnaces and billet heating have advanced. Improved methods of deoxidizing steel in melting and closer temperature control in casting have improved die steels. Inspection of dies and die steels is more stringent. VSP (4b)

Handling and Heating Heavy Ingots. Ronald Benson. *Mechanical Handling,* Vol. 23, Mar. 1936, pages 67-69. Abstract of paper "The Technique of Forging," read before the Manchester Association of Engineers. JCC (4b)

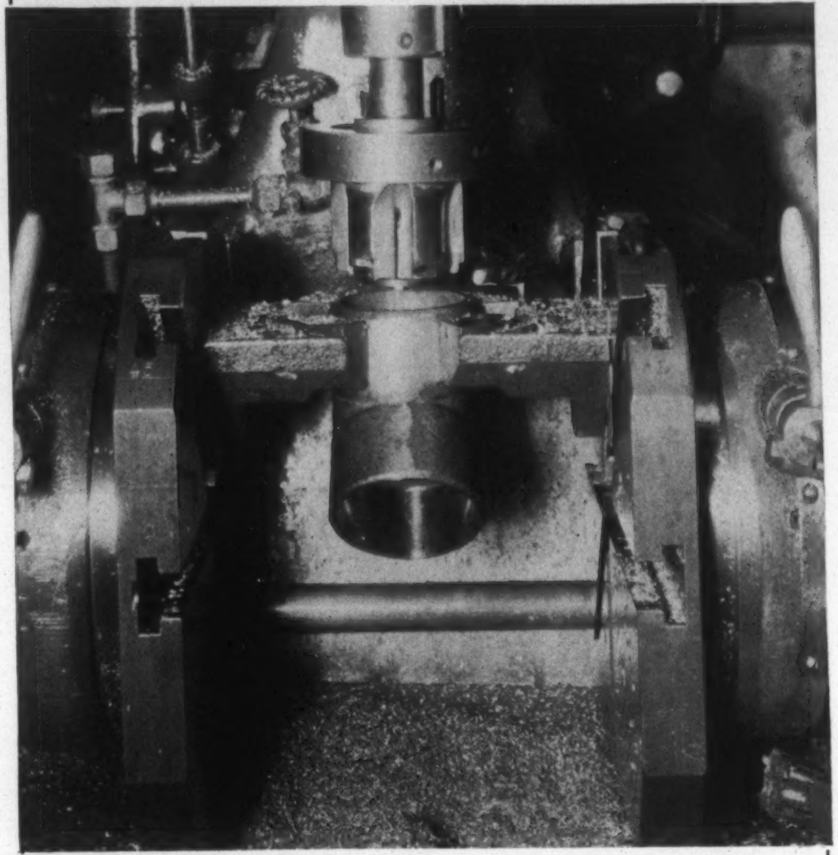
4c. Cold Working, including Shearing, Punching, Drawing & Stamping

Hot-Pressed Light-Metal Parts (Warmgepresste Leichtmetallteile) Reichenbach. *Aluminium,* Vol. 18, Mar. 1936, pages 100-102. Al and its alloys with Mn, Si, Mg-Mn, Mg-Si and Cu-Mg are very suitable for manufacturing parts by hot-pressing. A table shows the mechanical properties and test results; while Brinell hardness of cast and hard-pressed materials were about the same, tensile strength and elongation were much superior for the pressed parts, and the structure is more uniform and dense than in a cast piece. Ha (4c)

Effect of Annealing on Release of Internal Stress in Cold-drawn Rods. Kisuke Saito. *Kinzoku no Kenkyu,* Vol. 12, Dec. 1935, pages 551-558. In Japanese. The effects of annealing on the release of internal stress and the hardness change in cold-drawn rods were studied. 7 kinds of metals, i.e., Cu, brasses (70 : 30 and 60 : 40), Armco Fe and steels containing 0.3, 0.8 and 1.3% C were used for the present investigation. The release of internal stress was inferred from the change of length of the rod, measured in the direction of drawing under room temperature, to which the specimen was cooled down slowly in a furnace after the annealing at different temperatures for half an hour; the annealing was repeated at successively high temperatures. In general, the length of the rod contracts in the case of Cu and brasses in the whole range of annealing temperature, but in the case of iron and steels, it elongates in a certain range of temperature and afterwards contracts. The amount of the change of length of the rod in the former case is smaller than in the latter case. The temperatures, at which the internal stress is released, are about 300° for Cu, 370° for brasses and 650° for Fe and steels respectively, and the increased hardness due to cold-working is reduced to its original value in the vicinity of these temperatures. KT (4c)

Drawing of Stainless Steel (Etirage de l'acier inoxydable) L. Roy. *Métaux,* Vol. 10, Dec. 1935, pages 299-302. General discussion on forming of stainless steel sheets. GTM (4c)

Cut Manufacturing Costs . . . In Half



FIRTHITE on this operation is used to bore and face cast-brass pipe elbows. The cutter head has seven inserted-type blades —six that finish the bore to size, and one mounted in an adjustable sleeve, that faces and forms the edge—all FIRTHITE tipped. The cutter operates at 400 feet per minute, produces up to 5000 pieces between tool grinds and offers a total life of more than 80,000 pieces.

Quoting the Works Manager, "Our tool costs has been slashed to less than half by using FIRTHITE on more than 85 per cent of all operations in our plant. We could not get along without FIRTHITE because it has proved to be the most economical cutting material. If we had to go back to former tools, our manufacturing cost would be doubled and it would be quite difficult to obtain the accuracy and finish which are now so easy to get with FIRTHITE Sintered Carbide Tools."

FIRTHITE engineers are available for consultation.

Distribution of Internal Shearing Stress in Many Twisted Metallic Rods and Their Changes Due to Annealing. Tarô Uêda. *Kinzoku no Kenkyu,* Vol. 13, Jan. 1936, pages 1-19. In Japanese. Measurement of elastic after-effect was made on Armco Fe, C steels (0.2, 0.4, 0.6, 0.7, 0.9, 1.1, 1.3% C), Cu and Mg, to all of which twisting deformation was previously applied. In C steels a eutectoid steel having 0.89% C showed the highest elastic after-effect. The time required to attain an equilibrium condition of this sample was about 70 hours, but with other samples, was not longer than 40 hours. The distribution of internal shearing stress in the cross-section of specimens which attained the equilibrium condition was also measured. In the exterior of specimen bar the internal shearing stress acts in such a direction that the given twisting deformation might be advanced, while in the interior it acts in the direction of recovery. The twisting moment thus produced on the periphery of the center by these 2 kinds of internal stress bearing opposite sign is equivalent in magnitude but is in opposite direction, and hence they maintain mutually an equilibrium condition. Since internal stress was found to be distributed in the interior of sample bar which was given twisting deformation, the decrease of the stress due to annealing at various temperatures was studied. It was found that a large portion of the stress disappeared in the range of temperatures 300°-500° C. in the case of Fe and C steels, 100°-400° in the case of Cu, and 50°-200° in the case of Mg. The change of microstructure due to variation in temperature at a fixed position in Armco Fe which was given twisting deformation by the amount to 0.2 π/cm. was studied. In order to examine the changes in property due to variation in temperature, specific gravity and surface hardness (by a Vicker's hardness tester) of some metals were also measured. The results were found to agree satisfactorily with each other. As the internal stress decreases during annealing, it was studied by measuring the change of deformation of 15 kinds of metal heated under a fixed rate in vacuum. The change of deformation observed in this experiment was attributed to the recrystallization as well as to the growth of grains. Latent energy due to the presence of internal stress was also measured; it was about 0.2% of the applied energy in the case of 0.9% C steel, 0.12% in the case of 1.3% C steel, 0.18% in the case of Mg, and still less in the case of other metals.

Getting Results with Sintered Carbides. Frank W. Curtis. *Modern Machine Shop,* Vol. 8, May 1936, pages 48-60. Principles to be observed in the use of carbide tools, their shapes as dependent on material to be machined and manner of support are explained in detail.
Ha (4d)

Factors Influencing the Nature of the Cutting Speed-Tool Life Curve. O. W. Boston, W. W. Gilbert & C. E. Kraus. *Transactions American Society for Metals,* Vol. 24, Mar. 1936, pages 186-212. Paper and discussion from the Chicago Convention of the Society, 1935. Data presented show that the slope and vertical position of log cutting speed-log tool life curve will be changed by change of tool shape, change of brand of steel, analysis or treatment of material cut. Cutting fluids produce characteristic curves. Results differ between shallow thick cut and deep thin cut. Fluids cause the log curve to be steeper on shallow thick cut and flatter on deep thin cut. Data are presented on the merits of several cutting fluids.
WLC (4d)

Some Factors Affecting the Machinability of Steels and Other Alloys. *Metal Progress,* Vol. 29, Jan. 1936, pages 31-34. Discussion at meeting of Cleveland Chapter A.S.M. A low ductility and low strength tend to make machining easy. Low ductility (proper degree of dynamic brittleness) prevents the chip from clinging to the stock of balling up on the tool. Low strength makes for less power in separating the metal. A discontinuous structure makes for good machinability, a single phase matrix is improved by the presence of an insoluble constituent. MnS in screw stock, carbides in spheroidized tool steel and lead in brass are some of the examples discussed under this head.

5. HEAT TREATMENT

O. E. HARDER, SECTION EDITOR

Nitrate Salt Baths for the Heat Treatment of Duralumin and Dangers They Present (Bano de sales a base de nitraotos para el tratamiento termico del duraluminio y pelogros que presentan) Ernesti Schenkel. *Metalurgia y Construccion Mecanica,* Vol. 2, June 1936, page 10. Studies are presented which have been made to determine the origin of the dangers of explosion which were formerly common with the use of nitrate salt baths for heat treatment.
FRM (5)

■ 5a. Annealing ■

Effect of Heat Treatment Between A_1 and A_3 on the Structure and Notch-Toughness of Low-Carbon Steels (Einfluss von Wärmebehandlungen zwischen A_1 und A_3 auf Gefüge und Kerbschlagzähigkeit kohlenstoffarmen Flussstahls) E. Dobinsky & H. Hanemann. *Archiv für das Eisenhüttenwesen,* Vol. 9, Jan. 1936, pages 359-366. By annealing between A_1 and A_3 the notch bar impact resistance of low-carbon steel can be raised over that in the normalized condition. This results from a change in the form of the pearlite (tending toward spheroidization). There was no change in grain size.
SE (5a)

The Bright Annealing of Silver in Gas Furnaces. P. Hopkinson. *Metal Industry,* London, Vol. 47, Dec. 20, 1935, page 614. A brief description of a process recently installed by a Sheffield (England) firm whereby a furnace of the continuous process type, heated by town gas, produces Ag thoroughly annealed, bright and free from "fire." The annealed material is discharged down a chute sealed in the water of the quenching tank. The air-gas ratio, which is kept constant, heats beds of broken refractory to incandescence which, reflected to the arch of the furnace, heats the Ag by radiation. The furnace handles 2000 oz. Ag/hr. on a gas consumption of 280 ft.^{3}/hr. The furnace was designed by Messrs. British Furnaces, Ltd. of Chesterfield.
HBG (5a)

■ 5b. Hardening, Quenching & Drawing ■

Methods of Hardening Cast Iron by Heat Treatment. J. S. Vanick. *Metal Progress,* Vol. 29, Jan. 1936, pages 40-43. Cast Fe can be hardened in same way as steel and its hardening power depends upon composition and structure of the matrix and distribution of graphite. Fine graphite and freedom from carbide masses or clusters, a tendency to harden evenly and deeply as cast and easy machinability are desired. Best compositions to obtain this result are low Si Fe for they are initially finer grained and less inclined to graphitize. High test Fe of low total C (2.80%) is also suitable, here Si should be low. In this latter type alloy additions enhance the value of heat treatment. Ni is especially effective by retarding graphitization and making for better carbide distribution. Cr and Mo increase depth of hardening. Microstructure exclusive of graphite should be that of 0.60%-0.85% C steel, martensitic, sorbitic or troostitic, but clear of carbide masses or free ferrite. Soft Fe of high Si will graphitize further in heat treatments. In all heat treatment of cast Fe heating time should be held as low as possible on this account. Quenching should be done in oil from temperatures of 1450°-1550° F. varying with alloy present. Application of hardened cast Fe to cylinder liners is described where composition of approx. 0.65% Cr, 2.0% Ni, Si 2.0%, total C 3.25% is used. A 500 Brinell cylinder has 3 times the life of a cylinder 240 hard. Possibilities of nitriding and cyaniding cast Fe are discussed. Pack hardening is probably of questionable value.
WLC (5b)

Heat Treated Rails for Special Trackwork. Edwin W. Goodaire. *Metal Progress,* Vol. 29, Mar. 1936, pages 59-64, 92. Describes development of heat treating equipment and technique used in making special trackwork of quenched and drawn rails. Data given show remarkable uniformity of hardness throughout the section of treated rails, Brinell 321 at center of head to 375 at surface.

DUCTILE KANTHAL LONGER LIFE

Here illustrated are two sections of Kanthal Wire coiled on mandrils and stretched when cold. It answers the query, "Is Kanthal ductile."

Send for sample and make your own test.

Kanthal D is indicated where greater resistance and longer life is desired than is available with nickel chromium alloys.

Kanthal A and A-1 have safe operating temperatures 300° to 400° higher than nickel chromium. Kanthal wire is drawn exclusively in the United States in our own Wire Mills at Southport, Conn.

MISCO "Centricast" Furnace Conveyor Rolls

(Centrifugally Cast)

NO mechanical joints are used in the manufacture of Misco "Centricast" Furnace Conveyor Rolls. The end castings are *flash welded* to the centrifugally cast tube. Misco "Centricast" furnace rolls combine light weight with rugged strength. *Your inquiries are invited.* Michigan Steel Casting Company, 1981 Guoin Street, Detroit, Michigan.

Part of a recent shipment of 173 Misco *flash welded* "Centricast" Furnace Conveyor Rolls.

MISCO

Heat and Corrosion Resistant Alloys

Solve Your Air Supply Problems Like This

The next time you buy heat-treating equipment, ask your manufacturer to mount the Spencer Turbo-Compressor on the unit. The clean-cut and practical installation shown below is a typical example.

Only a Spencer can combine the required qualities of simplicity, small size, freedom from vibration and the reliability necessary for applications like this.

And throughout the years it has been the Spencer with its centrifugal design, light-weight impellers and wide clearances that has won the outstanding recognition of metal men in all branches of the industry.

Such installations not only look neat and businesslike but often enable entire departments to clean up their layouts and reorganize their production methods.

While on this subject, don't forget that Spencer Vacuum Cleaning Systems are being used more and more every year, particularly where dirt or dust are injurious to employees or the finished product.

May we look over your plant and suggest what might be saved by cleaning the Spencer way?

5c. Aging

Age-Hardening Alloys and Their Application. R. H. HARRINGTON. *General Electric Review,* Vol. 39, Mar. 1936, pages 124-127. Types of age-hardening reactions discussed are simple precipitation hardening and simple lattice-strain hardening. Other causes of age-hardening effects are: (1) gas reactions within a metal lattice, (2) single solid solution phase in a quenched alloy may upon reheating entirely transform into a compound or into 2 solution phases of which either one or both may be harder than the original, and (3) recrystallization of cold worked metals or alloys to a finer grain size or efficient precipitation of a new phase along the lattice planes of maximum slip or deformation. Methods of research used are (1) cut-and-try method of varying the compositions and heat treatment of alloys already known to be age-hardening and employing additive elements in new compositions, (2) studying prospective alloys by means of the available knowledge recorded in the binary and ternary equilibrium diagrams of the involved elements. Applications of age-hardening alloys discussed include tool materials, duralumin alloys, Cu-Be alloys and Cu-Be-Co alloys especially useful for resistance welding electrodes. CBJ (5c)

Aging of Nickel-Beryllium Alloys (Über die Vergütung von Nickel-Beryllium Legierungen) WALTHER GERLACH. *Naturwissenschaften,* Vol. 24, Apr. 3, 1936, page 218. The magnetic properties of a Ni-2% Be alloy after heating and quenching from 1200° C. are: coercive force, less than 1 oersted, remanence about 10%, Curie point, 80-100° C., I_∞, 200-220 cgs. After annealing at 500° C. for 3 hours the magnetization increases 50%. The coercive force rises to about 100 oersted and the Curie point to 260°-270° C. This behavior is explained as due to aging. The Be separates leaving a Be-poor solid solution with a higher Curie point. The distorted solid solution presents a high magnetic hardness. The alloy is quite stable after the aging treatment as further heating at 300° C. does not effect any change. HAS (5c)

5e. Carburizing

Investigation of the Material of Sewing Machine Parts. Part III. H. KISHIMOTO. *Kinzoku no Kenkyu,* Vol. 12, Nov. 1935, pages 514-521. In Japanese. Specimens having various thicknesses were carburized under several conditions by means of the gaseous cementation process and the change of their length due to quenching was measured. It was found that the change of length for a comparatively thick specimen is in general smaller than that for a thin one. For the specimens having same thickness and carburized to the same depth, the relation between the elongation and ratio of thickness for carburized and uncarburized layers is as follows; the elongation becomes larger as the ratio of thickness of the layers gets smaller and vice versa. For the specimens of thin plate which could be carburized into the interior, the elongation increases in direct proportion to the C content. The change of length for quenched specimens after being aged was also measured. HK (5e)

Sodium Cyanide—Its Application in the Heat Treating and Finishing of Iron and Steel. F. E. D. GRIGGS. *Canadian Chemistry & Metallurgy,* Vol. 20, Apr. 1936, pages 112, 114. A brief discussion of NaCN carburizing. Advantages claimed for cyanide casehardening are: (1) saving in labor, (2) accurate control of depth of case, (3) freedom from distortion, (4) elimination of exfoliations, (5) a clean bright finish, and (6) required equipment is inexpensive. Other uses for cyanide are mentioned. WHB (5e)

Soft Spots on Hardened Steel. H. H. BLEAKNEY. *Iron Age,* Vol. 136, Dec. 12, 1935, pages 32-33, 94, 96. Based on Ehn and McQuaid's work on case carburizing, and also on work of other investigators, discusses formation of soft spots in hardened steel. Successful hardening of steel depends on method used, and inherent hardenability of steel. Author suggests that non-metalic inclusions or carbide affect the critical cooling rate, and therefore soft spots are formed when normal hardening speeds are used. In carburizing, dirty steel should be avoided. A case of eutectoid is desirable as a precaution against the formation of soft spots. Where case of excess C is used, final quenching temperature should be high enough to effect complete solution of excess carbide. VSP (5e)

Continuous Carburizing of Screws with City Gas. JOHN A. COMSTOCK. *Metal Progress,* Vol. 29, Apr. 1936, pages 44-46. Describes equipment and carburizing procedure conducted in rotating retort where the work slowly rolls through heating and carburizing zones and falls into quench through gas filled chute. Undried city gas diluted with products of combustion is carburizing medium. Speed of retort and temperature are controls used on depth of case and the ratio of raw gas to products of combustion controls C concentration in case. WLC (5e)

5f. Nitriding

Nitriding Steels and Nitriding. C. S. CUTCHER. *Heat Treating & Forging,* Vol. 22, Apr. 1936, pages 178-181. Paper read before the Steel Treatment Society, Australia. Outlines development of nitriding, gives composition of steels most generally used, and describes fabrication, nitriding process, advantages of nitride case, and applications. MS (5f)

Nitriding of Austenitic Steels. BRYMOR JONES. *Metal Progress,* Vol. 29, Feb. 1936, pages 39, 72. See *Metals & Alloys,* Vol. 6, Sept. 1935, page MA 358R/7. WLC (5f)

6. FURNACES, REFRACTORIES AND FUELS . . .

M. H. MAWHINNEY, SECTION EDITOR . . .

Insulation of Open-Hearth Furnaces. Survey of Results Obtained and of Materials Used. EDWIN F. CONE. *Metals & Alloys,* Vol. 7, Apr. 1936, pages 109-118. Questionnaire to 30 steel ingot and casting producers shows insulation used partially or completely. Complete insulation of furnaces is reported variously as producing no benefits to 30% increase in life. Reports returned are practically unanimous in production of fuel savings by insulation, estimates ranging from 5-30%. Various refractories used for insulation are described. Temperature limit control apparatus is described and briefly discussed. WLC (6)

Quality Brass and Copper Demand Quality Fuel. WENDELL L. CROSS. *Industrial Gas,* Vol. 14, May 1936, pages 9-10. A gas-fired pot furnace for tinning and bright-annealing in an atmosphere of steam is described. To avoid water stains on the Cu a cracked gas with about 1% CO and an air-gas ratio of 4:1 is used for cooling atmosphere. Ha (6)

New Electric Process for Cyanide and Activated Baths. E. F. DAVIS. *Metals & Alloys,* Vol. 7, June 1936, pages 143-146. Describes resistance heated salt bath furnace. Temperature distribution in pot 37" x 27" x 20" varies less than 5° F. Due to heat being applied internally (resistance effect in salt) the pot life is greatly increased. The heat insulation is effectively applied to reduce radiation losses. Cost figures are comparable to those for gas fired salt baths. WLC (6)

Special Methods of Gas Firing to Avoid Scale and Soft Skin. WINFIELD FOSTER. *Metal Progress,* Vol. 29, Jan. 1936, pages 51-52. Describes temperature and fuel-air proportioning controls for gas fired forge furnaces in which a relatively high pressure is maintained. Decreases of 66% in decarburization and 75% in scaling with more uniform product and greater comfort of workmen have been made possible. WLC (6)

Gas Firing Improves Columbia Tool Steels. WINFIELD FOSTER. *American Gas Journal,* Vol. 144, Feb. 1936, pages 31-32. Installation of gas-firing equipment is described. Finished product is improved in quality and scale loss has decreased. CBJ (6)

Heat Transmission in Steel-reheating Furnaces. J. E. EBERHARDT & H. C. HOTTEL. *Transactions American Society of Mechanical Engineers,* Vol. 58, Apr. 1936, pages 185-193. Some empirical formulas for the design of reheating furnaces are derived from tests with 5 continuous furnaces of different types; the tests are described. 5 references. Ha (6)

Notes on Copper Refinery Furnace Firing and Refractories. H. C. ROBSON. *Metal Industry,* London, Vol. 47, Oct. 18, 1935, pages 395-397, 402; discussion Nov. 22, 1935, pages 507-511. Paper presented at meeting of Institution of Mining & Metallurgy, Oct. 17, 1935, is based upon work conducted for the purpose of effecting fuel and refractory economies at the furnaces of the Indian Copper Corp., Ltd. The plant had 2 refining furnaces, each of which was large enough to handle full production. One furnace used pulverized coal and the other was grate-fired, using lump coal. The second furnace was changed to use pulverized coal as this method was found to reduce fuel cost 55%. The advantages of pulverized coal firing over grate firing are listed. The burners used were redesigned to increase efficiency and waste heat was utilized to heat feedwater. High-grade fire clay bricks—containing 70% Al_2O_3—and magnesite bricks were tried as substitutes for more expensive silica lining containing 90% ground quartzite and 10% fire clay, but without success. Eventually larger sized bricks of the original material proved to be an economy as the number of joints was reduced. A change from a fixed roof to a detachable roof proved to be another economy. The advantages of this type of roof are cited. HBG (6)

The Employment of Blast Furnace Gas Industrial Furnaces with the Aid of Steel Recuperators. A. SCHACK. *Demag News,* Vol. 10C, Mar. 1936, pages C1-C8. The advantages to be obtained by preheating gas and air when using blast furnace gas, and the practical utilization of the principles are explained. A continuous ingot heating furnace for an hourly output of 25 tons, heating the cold ingots to 1250°-1350° C. is described in detail, and the thermal balance made up. The thermal efficiency for the air recuperator is 78%, that of the gas recuperator 67%. Ha (6)

Physical Aspects of Refractory Insulation. JOHN D. SULLIVAN. *Brick & Clay Record,* Vol. 88, Feb. 1936, pages 74-76. To decrease heat flow use: (1) a thick wall of dense brick, (2) a light-weight or porous brick, (3) a combination of dense and light brick, (4) a combination of dense brick and some loose or non-shaped insulation. Light-weight brick may be used (1) as a light-weight structural material and (2) as an insulating material. Light weight brick are porous and are not suited for use as containers for metals, glasses or slags. They may be used as back-up materials for walls of furnaces or for operations not involving liquid states. CBJ (6)

The Temperature Difference Method of Open-hearth Furnace Reversal. A. SMITHSON. *Metallurgia,* Vol. 13, Apr. 1936, pages 188-190. Discusses systems and and describes semi-automatic system based on temperature differences of thermocouples located just outside cold end of checker work. JLG (6)

P. B. Sillimanite for Hearth Tile

Our P. B. Sillimanite Hearth Tile are used extensively in heat-treating and annealing furnaces because of its high refractoriness, freedom from spalling and high mechanical strength when hot.

Many industrial furnace builders use this tile as standard equipment—its consistently high quality has been well established by years of satisfactory service.

Typical of P. B. Sillimanite manufactured by The Chas. Taylor Sons Company, this tile is not affected by oxidizing or reducing atmospheres, and there is no tendency to grow or warp while in service.

Perhaps it is the kind you need for lowering overhead cost and increasing profitable production. Consult our Engineering Department for a frank and fair expression of its adaptability to your problem.

"Shamva" Mullite Roof for size QV Moore Lectromelt

FOR EXTRA SERVICE ROOF YOUR ELECTRIC FURNACE WITH "SHAMVA" MULLITE

A roof of "Shamva" Mullite installed in your Electric Furnace will deliver from 3 to 5 times the service of a roof of silica or clay refractory.

This is due to the very low co-efficient of expansion of Mullite, and the consequent indifference to thermal shock—which practically eliminate spalling.

Not only does such a roof greatly increase the possible number of melts, but it also keeps them free of contamination from falling scale. The shapes fit perfectly and are easily installed.

"Shamva" Mullite Roofs are made for Moore Lectromelt, Herroult, Greene, Snyder and Booth Electric Furnaces.

SEND FOR CATALOG

Applications of Controlled Atmospheres to Heating. T. B. Bechtel. *Heat Treating & Forging,* Vol. 22, Jan. 1936, pages 39-42. **Practical Applications of Controlled Atmosphere Furnaces.** *Industrial Heating,* Vol. 3, Apr. 1936, pages 221-228. Conditions which make the use of controlled atmosphere in heat treating furnaces necessary are discussed and equipment and types of furnaces suitable for such control are described. Ha + MS (6)

Presents Detailed Data for Construction of Small Size Cupola. H. W. Kelly. *Foundry,* Vol. 64, Feb. 1936, pages 34, 84. Describes a small unit for melting alloyed mixtures of ferrous and non-ferrous metals for experimental purposes. VSP (6)

Increased Economy by Modern Heating Methods for the Hardening Shop (Gesteigerte Wirtschaftlichkeit durch moderne Feuerstätten der Härterei) Otto Lich. *Automobiltechnische Zeitschrift,* Vol. 39, Apr. 10, 1936, pages 183-186. Salt baths, heating furnaces, burners and general equipment for hardening processes, and for producing and controlling temperatures up to 1300° C. are reviewed and special features described. Ha (6)

Stevens Open Hearth Furnace. *Blast Furnace & Steel Plant,* Vol. 24, Feb. 1936, pages 157-159. Same as "Furnace Design and Operation," *Heat Treating & Forging,* Dec. 1935. See *Metals & Alloys,* Vol. 7, May 1936, page MA 234R/2. MS (6)

Waste-heat Boilers in Open-hearth Practice. *Iron & Steel Institute,* Special Report No. 10A, May 1936, 63 pages. Discussion, correspondence and committee's reply to Report No. 10. See *Metals & Alloys,* Vol. 6, Dec. 1935, page MA 494R/8. JLG (6)

Production and Uses of Insulating Firebrick—Advantages in Furnace Construction. *Metal Industry,* London, Vol. 47, Dec. 20, 1935, pages 608-610, 619. This type of firebrick is a new development in refractories. While well established in some industries its use is somewhat limited. Reference is made to the paper recently contributed to the Refractories Materials Section of the Ceramic Society by Dr. F. H. Norton, Assoc. Prof. of Ceramics at Mass. Inst. of Tech. Only within the last 5 years has the advantage of the use of insulation inside the furnace been recognized. This led to the development of insulating firebrick. The 4 general methods of producing the necessary porous structure are (1) formation of bubbles in the soft mix, (2) the addition of a porous material, e.g. infusorial earth, (3) the burning out of organic material in the mix, and (4) the sublimation of solid particles in the mix. The physical properties of some commercial bricks are discussed. These include weight, porosity, thermal conductivity, after shrinkage, hot and cold strengths and spalling tests. The advantages of this type of firebrick are low heat storage capacity, low thermal conductivity, a more uniformly heated product, greater efficiency of combustion and the sound-absorbing property of the brick. The chief limitations are lack of resistance to slag, low resistance to abrasion, low resistance to mechanical vibration and low resistance to spalling. Methods of use in furnace design are discussed. HBG (6)

Use Petroleum Coke to Raise Temperature of Iron in the Cupola. James A. Murphy. *Foundry,* Vol. 63, Dec. 1935, pages 35, 78. Having difficulty in obtaining heat above 2400° F., the author used petroleum coke with a fixed C of 86.50%. Results showed that metal temperature at the spout was never below 2700° F. and a few readings showed 2750° F. VSP (6)

Experiences on Automatic Temperature Controllers of Gas-Fired Industrial Furnaces (Erfahrungen mit selbstätigen Temperaturreglern an gasbeheizten Industrieöfen) H. O. Meyer. *Die Wärme,* Vol. 58, Dec. 14, 1935, pages 819-824. The 2 principal methods of controlling gas-fired furnaces are given, the controllers are described and special attention is devoted to the control of furnaces having a larger heat capacity. EF (6)

Development of the Continuous Vitreous Enamelling Furnace. W. Marshall. *Sheet Metal Industries,* Vol. 9, Dec. 1935, pages 774-776. A paper before the Institute of Vitreous Enamelers. A general discussion pointing out the advantages of the U-type furnace. AWM (6)

New Combination Color Pyrometer with Comparison Lamp (Ein neues kombiniertes Farbpyrometer mit Vergleichslampe) G. Naeser. *Archiv für das Eisenhüttenwesen,* Vol. 9, Apr. 1936, pages 483-485. Previously used optical pyrometers give uncertain results because of the uncertainty of the black body conditions of the temperature source. A combination color-brightness pyrometer is described which enables obtaining the true temperature of a continuous spectrum radiator within ± 10° C. Whether or not black body conditions exist can be ascertained by a single measurement. SE (6)

Infiltrated Air in Furnace Operation (Falschluft im Ofenbetrieb) H. Schwiedessen. *Archiv für das Eisenhüttenwesen,* Vol. 9, Jan. 1936, pages 319-326. Infiltrated air results from low pressure in the furnace chamber and loose places in the brick work. Infiltrated air lowers the temperature differential between the incoming and outgoing gases and raises the amount of gases going up the stack, causing lower output and higher fuel consumption. Proper use of chimney dampers, tight brick work, avoidance of superfluous doors and openings, and proper design of furnace chamber can lower the amount of infiltrated gases. The furnace can also be run with excess gas pressure, particularly after infiltration of air occurs. SE (6)

Box-type Furnace with Air Circulation for Heat Treatment of Coiled Strips of Light Metal (Der Schachtglühofen mit künstlicher Luftumwälzung zur Warmbehandlung von Bandringen aus Leichtmetall) O. Gengenbach. *Elektrowärme,* Vol. 5, Apr. 1936, pages 113-122. Examples of different types of furnaces, methods of control and heating in definite schedules are described and illustrated. Ha (6)

Graphite Resistor Radiation Furnaces. Henri George. *Metal Industry,* London, Vol. 47, Nov. 8, 1935, pages 469-470. See *Metals & Alloys,* Vol. 7, Apr. 1936, page MA 190L/4. HBG (6)

7. JOINING

7a. Soldering & Brazing

C. H. CHATFIELD, SECTION EDITOR

Soldering and Jointing. Aluminum and Copper to Aluminum. F. P. Morrough. *Electrician*, Vol. 116, Apr. 24, 1936, page 532. Use of Al in the electrical industry has made necessary methods for joining Al to Cu and to Al. Molten solder breaks down the oxide film of Cu and brass but is ineffective with the oxide film on Al. Surfaces to be soldered should be "tinned". 60% Sn 40% Zn solder gives satisfactory results, best solder for Al joints is 60% Zn and 40% Cd solder. CBJ (7a)

Recent Advances in Soldering and Brazing. C. L. G. Ashby. *Metal Industry*, London, Vol. 47, Aug. 16, 1935, pages 151-153. Points out that an essential property of soldering is that it alloy with the metals being joined. This is dependent upon the fluidity of the solder, its affinity for the alloys in question, and the efficiency of the flux used. Soldering and brazing are compared with welding and it is shown that the temperature at which the joining is done is, perhaps, the major difference. There is not, as yet, a generally suitable solder alloy for use at a temperature within the range of 350°-600° C. This is due to the exacting demands of modern requirements which are listed. Some Ag solders have been developed which meet some of the requirements. The old arbitrary mixtures of Ag and brass have been superseded by a series of alloys based on the ternary system of Ag-Cu-Zn, each of which is fitted to meet certain conditions. These alloys have been further modified by additions of other elements of which Mn, P, and Cd appear to yield the greatest benefits. At the lower end of the gap between "hard" and "soft" soldering greater difficulties are experienced due to the fact that these alloys form eutectiferous alloys with each other. However, alloys containing 2 or more of the metals Cd, Zn, Sn, Pb and Ag can be used successfully. Another major difficulty is the flux to be used. The 3-fold purpose of the flux is mentioned and examples given for both the low-melting as well as the higher-melting alloys. HBG (7a)

Brazing of Gray Cast Iron. G. van Alstine. *Industry & Welding*, Vol. 7, Dec. 1935, pages 15-17. The difficulties of bronze welding of gray cast Fe are discussed. Some practical hints are given. Preheating should not be above about 1300° F. The pieces should be cleaned thoroughly from all grease, scale and rust. Use of bronze or Mn-bronze rods with brazing flux is recommended, and cast Fe flux for difficult "tinning". Ha (7a)

Conservation of Tin. A. J. T. Eyles. *Sheet Metal Industries*, Vol. 9, Sept. 1935, page 563. Lower Sn content is not detrimental in many joining solders. Substitution of Cd for part of the tin is recommended. One with Pb 80%, Cd 10%, Sn 10% has about the tensile strength of 40-60 Sn-Pb solder and about twice the ductility. AWM (7a)

7b. Welding & Cutting

E. V. DAVID, SECTION EDITOR

Welded Structures from Scrap Material (Schweisskonstruktionen aus Schrottmaterial) E. C. Karch. *Autogene Metallbearbeitung*, Vol. 29, May 1, 1936, pages 137-138. Economies can be obtained by using material which usually is sold as scrap in welded constructions, which are often cheaper than castings and suit their purpose better. Ha (7b)

Further Studies on Internal Stresses in Ordinary Welded Seams (Weitere Untersuchungen über Eigenspannungen in einfachen Schweissnähten) F. Bollenrath. *Archiv für das Eisenhüttenwesen*, Vol. 9, Oct. 1935, pages 203-207. The contraction stresses in V-welds with bare and covered electrodes were determined by measuring the change in diameter of a drilled hole in the weld and the change in length of strips cut from the weld. Intermittent welding gave lower internal stresses than continuous welding. By proper subdivision of the seam (length of seam about 10 × thickness of plate) the stresses in the direction of the seam can be reduced to ⅓ the values in continuous welding; the transverse stresses remain the same. In thicker plates × seams gave lower stresses than V seams. SE (7b)

Status of Welding Technique in the Ruhr Mining Industry (Stand der Schweisstechnik im Ruhrbergbau) K. Baatz. *Glückauf*, Vol. 72, Jan. 18, 1936, pages 62-67. Observations and experiences in the use of welding in the repair of fractured machine parts, worn rails, boilers, etc. are reviewed. The necessity for having skilled welders is emphasized. Ha (7b)

The Welding of Pressure Vessels. S. F. Dorey. *Journal Institution of Petroleum Technologists*. Vol. 22, Apr. 1936, pages 211-223. The primary consideration in the welding of these vessels is the proper reduction of parent plate material. Main factors to observe are (1) differential freezing effect during welding; (2) electrolytic corrosion tendency between dissimilar metals; (3) physical properties of joint. The Committee on Welding in England has set the following requirements for plate material: C 0.1-0.2%, S 0.04% max., P 0.05% max., Mn 0.4-0.6%, Si 0.2% max. The steel should be acid or basic open hearth. Electrode requirements are: C 0.06-0.12%, Si 0.05%, Mn 0.4-0.5%, S and P 0.015% max.; the rods should be coated with a compound which produces a reducing gas shield to the weld, also a neutral slag; easy to apply; non-splattering; uniform deposit rate. The welding technique is discussed, manual vs. machine welding advantages, residual stress and strain relieving, and testing and inspection procedure. AAA (7b)

Relations Between Elasticity and Endurance Limit in Welds (Elastizitätsverhältnisse in Schweissverbindungen und deren Zugschwingungsfestigkeit) E. Diepschlag, A. Matting & G. Oldenburg. *Archiv für das Eisenhüttenwesen*, Vol. 9, Jan. 1936, pages 341-345. Tension-fatigue tests of arc and gas welds of structural steel indicated that the endurance limit was lower the greater the difference in elastic deformability between the base and weld metal. A high endurance limit of the weld was obtained when (1) the elastic deformability of the weld and base metal were nearly alike so that stress concentrations at changes in section were not high and (2) when the stresses were well distributed by inclining the seam in the direction of the tensional forces; a more gradual transition between the base and weld metal can also be obtained by deeper melting of the base metal. SE (7b)

Investigations into the Corrosion of Welded Steels in Humid, Warm Air (Untersuchungen über die Korrosion von geschweissten Stählen in feuchter warmer Luft) E. Diepschlag. *Autogene Metallbearbeitung*, Vol. 29, Apr. 15, 1936, pages 113-117. Comparative tests were made with Armco Fe and several (German) structural steels to find differences in the corrosion in warm, humid air when welded differently and later exposed to a current of steam at different temperatures. The results are shown in curves. It could be stated that the corrosion of welded samples under such conditions cannot be directly connected to the properties of the material, but that the method of welding and the nature of the welding rod can become of much greater importance and overshadow them. Ha (7b)

Modern Methods of Welding. C. H. Davy. *Chemistry & Industry*, Vol. 54, Dec. 6, 1935, pages 1054-1057; *Chemical Trade Journal & Chemical Engineer*, Vol. 97, Oct. 11, 1935, pages 305-306; Oct. 18, 1935, page 328. See *Metals & Alloys*, Vol. 7, Apr. 1936, page MA 190R/7. AAA + MS (7b)

Oxy-Acetylene Welding of Sheet Metals. A. J. T. Eyles. *Sheet Metal Industries*, Vol. 10, Feb. 1936, pages 172-174. General discussion of the welding technique for Al, Cu, brass, Mg alloys, and Zn and galvanized sheets. AWM (7b)

Developments in Welding Copper Alloys. I. T. Hook. *Iron Age*, Vol. 137, Feb. 20, 1936, pages 40-41. Discusses the welding of Cu alloy containers of all types to improve quality and economy in manufacture. The metal is largely Cu 96-98% with 1.5-4% Si, and the addition of one or more elements. Bronze welding has been much used the past year. Steam engine pistons or rings are coated with Mn bronze by oxy-acetylene. Be-Cu is finding many new applications. Use of Ambrac (20% Ni) and Supernickel (30% Ni) has increased for marine condensers. They are easily fusion welded. VSP (7b)

Advances Made in Welding of Aluminum. G. O. Hoglund. *Iron Age*, Vol. 137, Mar. 19, 1936, pages 46-47. Economies in joining Al by electric resistance spot, seam or butt welding have been utilized during 1935 for widely varying industrial applications. Equipment is now available in which the various steps are closely controlled. Commercial flash butt welding of Al for use on bicycle rims and automobile window trim was developed the past year. Advances in metallic arc welding of Al have been chiefly in expanding the field of application. Oxy-hydrogen torch is still the most widely used tool for Al welding. VSP (7b)

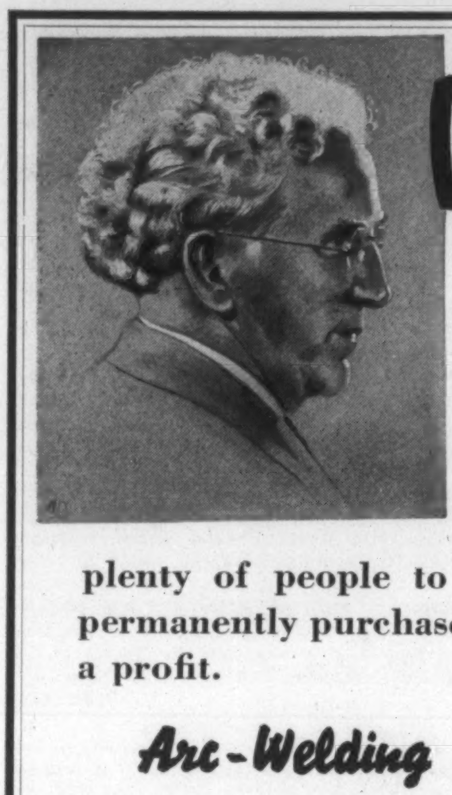
Tube Making in Australia. A. N. Hamilton. *Proceedings Australasian Institute of Mining & Metallurgy* No. 99, Sept. 30, 1935, pages 375-442, 463-464. Butt welding by the Bell process and by the Fretz-Moon continuous process is described in detail. AHE (7b)

Effect of Cold Work on the Welding Properties of Bare Electrodes (Der Einfluss der Kaltverformung auf die Schweisseigenschaften nackter Stahlelektroden) A. Kessner & H. Specht. *Archiv für das Eisenhüttenwesen*, Vol. 9, Nov. 1935, pages 231-239. How the welding properties of bare electrodes in the welding of structural steel St 37 and St 52 are affected by cold working and subsequent annealing was determined. Spattering, density of the weld, and the appearance of the bead, were unfavorably influenced by cold work. The dripping test frequently used for testing electrodes gave no correlation with the quality of the welds. The strength, elongation, and angle of bend of the welds, decreased with cold drawn electrodes and the welds gave a poor looking structure with inclusions and blow holes. The impact resistance increased, however. These effects of cold working were ascribed to the decrease in electrical and thermal conductivity of the electrodes. The rods get hotter during welding and melt faster, this being detrimental. SE (7b)

Welding and Cutting Technique at the Great Technical Fair in Leipzig in 1936 (Schweiss- und Schneidtechnik auf der Grossen Technischen Messe 1936 in Leipzig) H. Kemper. *Autogene Metallbearbeitung*, Vol. 29, Apr. 1, 1936, pages 97-108. A great number of welding, cutting, universal and special machines for gas and electric welding processes are described and illustrated, including burners, torches and equipment for surface hardening. Ha (7b)

Repairing the Oil Casings of Submarine Diesel Engines by Electric Welding. Maurice Lebrun. *Gas & Oil Power*, Vol. 31, Feb. 1936, page 52. Application of electric welding to repairing crankcases damaged by explosion is described. Time, labor, power, dimensions and strength of welds, and general difficulties and precautions are detailed. FPP (7b)

Welding in Bridge Work. A. R. Wilson. *Railway Engineering & Maintenance*, Vol. 32, Jan. 1936, pages 20-21. From paper presented before American Railway Bridge and Building Association Convention, October, 1935. Welding of bridge structures is historically and geographically reviewed. Welding bridge structures introduces unique problems, as compared to welding buildings, as more varied forms and sizes of structure, and hence more detailed design are involved. Advantages of welding over older methods of bridge construction and repair are cited and the advent of all-welded bridges for both highway and railroad is predicted. FPP (7b)



Whitey Sez:

Salesmanship is the power to persuade plenty of people to pleasurably and permanently purchase your product at a profit.

Arc-Welding Electrodes

Production of Diesel Locomotives. *Heat Treating & Forging,* Vol. 22, Apr. 1936, pages 174-177. **Modern Industrial Structures House Diesel-Electric Locomotive Plant.** *Steel,* Vol. 98, Apr. 13, 1936, pages 32-35. Description of plant of Electro-Motive Corporation at La Grange, Ill. Structural steel of buildings was erected by electric welding. There are several electric traveling cranes, the 200-ton crane being the largest unit of this kind ever welded. MS (7b)

Gas-fusion Welding in Steel Structures (Gasschmelzschweissung im Stahlbau) E. Bothmer. *Autogene Metallbearbeitung,* Vol. 29, Apr. 15, 1936, pages 119-120. The welding procedures used in the erection of a large hall of 30 x 48 m. with spans of 12 m. are described. Ha (7b)

Welded Plate Girder Bridges for Railways. O. Bondy. *Railway Gazette,* Vol. 64, Apr. 3, 1936, pages 652-654. Large welded bridges, increasingly common on railroads, impose new problems of design, workshop practice and particularly welding practice. Thermal distortion may be predicted and allowed for, and internal stresses reduced by use of rotary jigs to enable welding of plate girders in a horizontal position. Best electrode practice is to use small electrodes and to deposit thick welds in a number of layers. Coated electrodes are used for butt welds and bare electrodes for other joints. Latest developments and methods of evaluating quality, with special reference to German practice are discussed. FPP (7b)

Status of Electric Spot-welding for Aluminum and Its Alloys (Stand der elektrischen Punktschweissung für Aluminium und seine Legierungen) F. Bollenrath & W. Bungardt. *Aluminium,* Vol. 18, Apr. 1936, pages 125-133. The use of spot-welding of light metals is discussed from the point of view of their physical, chemical and structural properties. These require particular attention to current, form of electrodes, and pressure applied if a pure recrystallization weld is to be obtained. As comprehensive tests (which are described) have shown this is the desirable weld for strength and corrosion resistance. Ha (7b)

Cylinder Sleeve Welding. *Aluminium & the Non-Ferrous Review,* Vol. 1, Oct. 1935, pages 36-37. Procedure in repairing cracked cylinder block and sleeving the bores is described. Pure welding, bronze welding, and hard soldering were utilized. JCC (7b)

Proposed Uniform Test Procedure for the Qualification of Operators of Welding Equipment. *Welding Journal,* N. Y., Vol. 14, Dec. 1935, pages 25-26. Descriptive. WB (7b)

Welding Operations Aid in the Production of Machine Tools. F. B. Jacobs. *Welding Engineer,* Vol. 20, Dec. 1935, pages 30-33. Examples illustrate various applications. Ha (7b)

Welding Nickel-clad Steels. F. P. Huston & T. T. Watson. *Industry & Welding,* Vol. 7, Dec. 1935, pages 50-55. Methods used for welding with the metallic arc, C arc, acetylene and atomic H and preparation of work are described in detail. Ha (7b)

Electric Arc Welding and Its Applications VI. M. Maurice Lebrun. *Welding Journal,* British, Vol. 32, Nov. 1935, pages 326-328, 331. Continuation of discussion on electrodes and their characteristics as applied to welding of gray cast iron with mild steel, pure Ni, Ni-Cu (high Ni) welding rods; also with cast Fe rods after preheating. Rods for malleable Fe, Cu, bronze are briefly reviewed. WB (7b)

Welding in the Construction of the "Silver Jubilee" Train. *Welder,* Vol. 8, Dec. 1935, pages 773-777. Full description of design and welding is given. Ha (7b)

Gas Welding Applied to the Construction of Monuments (Die Autogenschweissung im Denkmalbau) B. Bibus. *Der Autogen-Schweisser,* Vol. 8, Sept. 1935, pages 97-98. Some characteristic examples are shown in which welding was advantageously applied to the assembling of complicated parts of monuments. WH (7b)

Assembling the New Steel Radio Tube by Electrical Resistance Welding. M. L. Eckman. *Welding Journal,* N. Y., Vol. 15, Feb. 1936, pages 10-12. Advantages for the metal tube are reviewed respecting electrical factors, production and ease of compact assembly in radio. The various steps of tube assembly are discussed and illustrated. WB (7b)

Resistance Welding. L. H. Frost. *Welding Engineer,* Vol. 21, Feb. 1936, pages 38-40; Mar. 1936, pages 32-33. Principles and practices involved, preparation of material and selection of electrodes are discussed in detail. Ha (7b)

Electrodes for Electric Resistance Welding (Les Electrodes pour Soudure Electrique par Résistance) J. Fassbinder. *La Technique Moderne,* Vol. 28, Feb. 15, 1936, pages 121-126. Cu is still much used for manufacturing electrodes. Pseudo-alloys of W and Cu ("Elkonite" and "Elmet") are also adopted for making tips of electrodes. Cu with additions up to 1% of elements entering into solution such as Co, Cd, Be is also used for making electrode tips. Some new products known as "Cuivrélect" and "Inuso" also give good results. Little is actually known about them. FR (7b)

Welding Hard Facings on Drilling Tools. J. Cuthill. *Journal Institution of Petroleum Technologists,* Vol. 22, Apr. 1936, pages 205-210; *Mining Journal,* Vol. 192, Feb. 15, 1936, page 122; Feb. 22, 1936, pages 155-156. The various hard facing materials fall in 4 classes: (1) Hard metal alloys, principally combinations of C, Cr, W, Mo, Ta, Co, and sometimes Fe (Stellite, Stoodite), (2) diamond substitutes, principally WC, to be embedded in cutting edges (Borium, Haystellite), (3) granular C substitutes, principally WC held in steel tubes (Tube Borium, Borod), and (4) WC powder for welding to steel with an electric arc (Blackor, Britor). Methods for their application to tools are described. AAA + AHE (7b)

A New Welding Process. *Gas & Oil Power,* Vol. 30, Sept. 1935, pages 211-212. Describes the Barimar-Sopromo oxy-acetylene coal gas welding process. Acetylene and coal gas are premixed and when burned with O provide a lower temperature welding flame than oxy-acetylene. Welds are purer because of decreased oxidation and, with cast Fe, avoidance of carburization; bubbling, heat-spreading and low-strength welds are eliminated. FPP (7b)

The Use of Welding in Transportation and Storage of Oil. A. C. Hartley & A. C. Vivian. *Journal Institution of Petroleum Technologists,* Vol. 22, Apr. 1936, pages 224-232. Welding effects great economies in pipe line construction, an approximate saving of 20% over screw-thread pipe. Welded lines enable higher working pressures with larger volume thru-put. The article gives complete description and data on pipe line construction in Iraq. AAA (7b)

Fusion Welding for Boiler Work. *Steam Engineer,* Vol. 5, Apr. 1936, pages 284-286. Arc welding is described. The properties of the weld metal, before and after deposition, are presented tabularly and photomicrographs of various parts of a weld are given. AHE (7b)

Welding of Rail Joints (Beitrag zur Schienenstoss-Schweissung) W. Miller. *Autogene Metallbearbeitung,* Vol. 29, Apr. 15, 1936, pages 120-122. Describes welding method used for joining rails of different heights of web which was made necessary in a railway tunnel. Ha (7b)

Long Welded Rails. *Railway Gazette,* Vol. 64, Mar. 6, 1936, pages 447-451. Reprint of paper presented by H. S. Clarke before Chicago Maintenance of Way Club. Primarily to increase travel safety the Del. and Hudson R. R. has installed continuous rails up to 6,970 ft. in length. Other disadvantages than accident hazard of jointed rails are discussed. Thermit pressure welding is used most although electric flash welding has been applied to a slight extent. Danger of long-track hot weather buckling may be obviated by welding the track in summer, as only inherent stress thereafter will be the increased tension in cold months, far below the elastic limit of rail steel. Two types of .35-.40 Mo and .04 max. P steels, differing slightly in C, Mn and Si contents are being welded. Details of construction are given. FPP (7b)

Eliminating the Rail Joint. *Railway Gazette,* Vol. 64, Mar. 6, 1936, pages 433-434. Description of advantages of and advances in use of long welded jointless rails on roads in Great Britain, France, and Germany is given. German technique stresses safety even with radical experiments. FPP (7b)

Welding in Locomotive Construction. *Railway Gazette,* Vol. 64, Feb. 28, 1936, pages 400-403. Illustrated description of electric welding of locomotive components, an operation that is gradually replacing the use of castings, riveted angle or flanged plates, is given. The use of positioning jigs and tack welding provides a higher degree of accuracy than is obtainable in steel castings of similar type and size. Welding of "smokebox saddle," "ashpan," cylinders, wheel spoke flaws, boiler joints, spring casings, etc. is described. Requirements to be satisfied before change to electric welding include: equivalence or superiority of quality of new unit compared to old cast or riveted work, minimum of machining, minimum weight consistent with requirements, economic advantage. Advantages claimed are elimination of costly patterns, continuous production of the welded unit and possibility of immediate local production eliminating excessive stock inventories. FPP (7b)

Welded Pipe Structure (Kleines Beispiel für die Praxis) H. Kreyenberg. *Autogene Metallbearbeitung,* Vol. 29, Apr. 15, 1936, pages 122-123. A structure for lifting 5000 kg. entirely welded together from pipes is described. Ha (7b)

The Training of Electric Welders. A. G. Poole & R. T. Rolfe. *Journal, Institution of Petroleum Technologists,* Vol. 22, Apr. 1936, pages 233-246. A semi-technical lecture course for apprentice welders, profusely illustrated with drawings of various types of welds, explanation of the welding technique, numerous photographs, micrographs, X-ray and other illustrations showing good vs. bad welds. Individual welder evaluation charts are given. AAA (7b)

Oxy-acetylene Welding. L. C. Percival. *Aluminium & Non-ferrous Review,* Vol. 1, Jan. 1936, pages 161-167; Feb. 1936, pages 202-207. Read before Swansea Local Section of Institute of Metals. A general account of the procedure in oxy-acetylene welding Al and its alloys, Mg alloys, brasses, and Cu; in bronze-welding cast Fe, Cu and steel; in hard-facing; in joining with Cu-P alloys, and in welding Zn-base die castings. JCC (7b)

New Importance of Welding in Construction. W. Spraragen. *Civil Engineering,* Vol. 6, Mar. 1936, pages 151-155. In designing welded structures, consideration must be given to such factors as residual stresses, stress concentrations, and the reduction of the amount of welding to a minimum. Examples of recent applications to pipe and gas-holder construction, buildings, and bridges are quoted. JCC (7b)

Improved Welded Structures by Combining Acetylene Welding with Acetylene Cutting Technique (Verbesserte Schweisskonstruktionen durch Verbindung der Azetylenschweiss- mit der Azetylenscneidtechnik) J. Sehring. *Autogene Metallbearbeitung,* Vol. 29, Mar. 1, 1936, pages 68-69. Some unusual fabricated structures, otherwise usually cast, are described. Ha (7b)

Resistance of Welded Machine Structures to Vibration. R. Tweetside. *Modern Machine Shop,* Vol. 8, Apr. 1936, pages 44-50. Besides the recognized advantages of welded structures, especially as machinery bases due to freedom from limitations of pattern, lighter weight and flexibility of construction, the vibrations caused by electric or reciprocating machinery can be much better overcome by suitably ribbing or stiffening the structure without the increase of weight as in cast structures. Examples are described. Ha (7b)

Modern Developments in Welding. C. G. Bainbridge. *Welding Journal,* British, Vol. 33, Mar. 1936, pages 81-84. General discussion of maintenance and repair. Practical problems in repair of castings and application of hard-facing are reviewed. WB (7b)

Arc Welding in Argon Gas. G. E. Doan & Wm. C. Schulte. *Welding Journal,* N. Y., Vol. 15, Jan. 1936, pages 23-27. See *Metals & Alloys,* Vol. 7, May 1936, page MA 241L/2. WB (7b)

Aircraft Requires Welding in Many Parts. Carl de Ganahl. *Metal Progress,* Vol. 29, Feb. 1936, pages 61-63. Describes fusion welding of 1% Cr, 0.25% Mo, 0.30% C steel and 18-8 stainless in aircraft. Spot welding is very satisfactory for 18-8 but not for Cr-Mo steel on account of air hardening effects. Addition of Ti and Cb to 18-8 prevents welding decay. WLC (7b)

Welded Pressure Vessels and Containers. C. H. Davy. *Welding Journal,* British, Vol. 33, Feb. 1936, pages 42-44. Discussion of papers presented at Symposium on Welding on this subject. WB (7b)

Resistance Welding in Refrigerator Manufacture. M. L. Eckman. *Machinery,* N. Y., Vol. 42, May 1936, pages 590-593. Newly developed methods and equipment used for flash- and seam-welding of thin sheets are described. Ha (7b)

Welding Sheet Aluminium. A. J. T. Eyles. *Aluminium & the Non-Ferrous Review,* Vol. 1, Apr. 1936, pages 340-342. The technique of welding sheet Al and Al alloy with the oxy-acetylene blowpipe is briefly described. JCC (7b)

High Pressure Piping. J. A. Freiday. Presented at 36th Annual Convention, *International Acetylene Association,* Vol. 12-15, 1935, 6 pages (available in mimeographed form from the offices of the Association, 30 East 42nd Street, New York, N. Y.); *Welding Journal,* N. Y., Vol. 15, Mar. 1936, pages 2-5. Erection and oxyacetylene welding of 8400′ long, 12¾″ O.D., ⅜″ wall, lap welded steel pipe line for high-pressure, high temperature out-of-door steam service between plants of U. S. Industrial Alcohol Co. and U. S. Industrial Chemical Co., Baltimore, Md. See also *Metals & Alloys,* Vol. 7, May 1936, page MA 242L/7. EVD + WB (7b)

Atomic Hydrogen Welding. A. L. Guest. *Metal Treatment,* Vol. 2, Spring 1936, pages 17-23. Atomic H arc welding equipment is described, and its operation and applications discussed. An exceedingly hot concentrated flame is obtained by blowing H through an arc between W electrodes. The most important application is for welding mild sheet steel, in which clean, sound, ductile welds can be made at high speeds. Curves showing welding speed and consumptions of current, W, and H when welding sheets of various thickness are given. Automatic machines are used for welding radiator elements. Atomic H welding is also used for constructing vacuum equipment, in which slag inclusions must be eliminated, and for joining special metals such as stainless steels, Nichromes, Ni, Monel metal, some brasses, Al and its alloys. JCC (7b)

Autogenous Cutting in Repairs (Autogenes Schneiden im Instandsetzungsbetrieb) H. H. Grix. *Autogene Metallbearbeitung,* Vol. 29, May 15, 1936, pages 154-155. Examples of unusual repairs and procedure of repairing by oxy-acetylene process with consumption of O and C_2H_2 are described. Ha (7b)

New Method for Welding Together Ferrous Metals by Application of Heat and Pressure. Leonard C. Grimshaw. *Engineering,* Vol. 141, Apr. 3, 1936, pages 383-386. **Bonding Ferrous Metals by Heat and Pressure.** *Steel,* Vol. 98, Feb. 24, 1936, pages 49, 51-54. H. S. RAWDON, SECTION EDITOR

8d. Electroplating

American Standards for Nickel Plating of Steel (Amerikanische Normung der Vernickelung von Stahl) *Nickel Berichte,* Vol. 6, Apr. 1936, pages 57-59. Fully discusses the tentative standards of Ni plating of steel of the A.S.T.M. and the American Electroplaters' Society with which the Master Electroplaters' Institute has concurred. The specifications also include life testing of platings under atmospheric service. EF (8d)

Development of Nickel Plating at High Current Densities in France (Entwicklung der Vernickelung bei grossen Stromdichten in Frankreich) *Metallwaren Industrie & Galvano Technik,* Vol. 33, No. 20, 1935, pages 435-437. Sufficient corrosion protection is afforded if the thickness of the coating is increased to 10 μ and 25 μ for Cu and Fe respectively. An accelerated Ni process (6 and 12 min. respectively) has been developed by applying current densities of 7-10 amps./dm.^{2} The hot plating solutions are stirred and in addition to Ni-sulphate, contain Ni chloride to facilitate the solution of the anodes, boric acid to prevent rapid changes of the acid content of the electrolyte, and Ni nitrate to minimize the adhesion of H-bubbles. Eleven different operations are required for this process which, however, works automatically. The porosity of the coating is tested by K-ferro-cyanide and the bond is checked by simple bending tests. EF (8d)

Nickel and Chromium Plating. Progress and Present Situation (Nickelage et chromage. Progrès et situation actuelle) M. Ballay. *Revue de Métallurgie,* Vol. 32, Oct. 1935, pages 494-500. See *Metals & Alloys,* Vol. 7, Apr. 1936, page MA 195L/6. JDG (8d)

Further Principles of Electrochemistry Applied to Electrodeposition. VIII. Buffering the Plating Solutions. Samuel Field. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 47, Oct. 11, 1935, pages 378-379. Author differentiates between strong and weak electrolytes as those that dissociate freely or only to a small degree in moderate dilution. Conductance is dependent upon the number of ions present in acids and on their rates of migration, e.g. Na acetate, when mixed with HCl, tends to resist H-ion concentration, i.e. it acts as a buffer. Some advantages, attributed to the presence of buffering agents in electrodeposition, are cited and certain reactions at the cathode and anode, in their absence are indicated. HBG (8d)

RODINE

MAKES PICKLING EFFICIENT

- UNIVERSAL ADOPTION. Rodine is cutting costs in 95 per cent of the country's pickling rooms.
- SAVES ACID AND METAL. Rodine more than pays for itself. By its use, economies of 30 to 60 cents per ton of metal pickled, are frequently gained.
- PREVENTS OVERPICKLING. Rodine eliminates pitting of the metal, minimizes acid brittleness, reduces rusting of pickled stock.
- SIMPLE TO USE. And by Rodine's use, the pickling operation is easily controlled and consistent in results.

CHEMICALS
ACP
PROCESSES

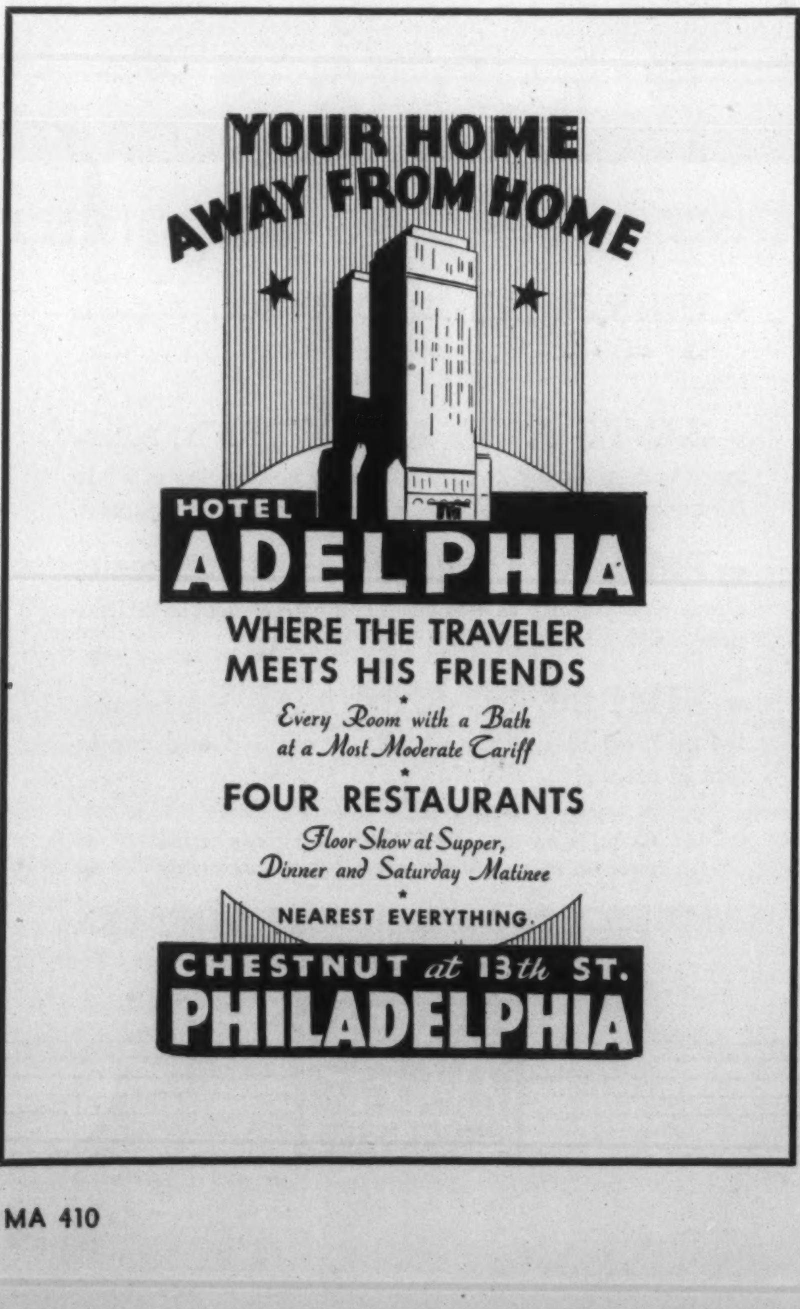
The Production of Non-Adhesive Deposits. E. A. Ollard. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 47, Nov. 22, 1935, pages 519-521. Usually in electrodeposition, as in electroplating, a high degree of adhesion is necessary. However, in electroforming and electrotyping, success depends upon the ready separation of the deposited metal from the base. The author tabulates and examines the processes of the latter type now existing. These are grouped as (1) the use of a metal base to which the deposit does not adhere, (2) protection of the metal base by wax or some other mechanically applied layer, (3) the formation of chemical films on base metal by treatment with reagents, (4) the formation of thin layers of other metals by chemical or electrochemical means, (5) combination of (3) and (4), (6) adsorbed colloid layers. The advantages and disadvantages of each group are indicated and specific applications are described. Group (3), which is deemed most important, is discussed in greatest detail. Methods of forming the film and the solutions used are described. HBG (8d)

Gilding and Silvering Large Metallic Surfaces. Yu. V. Baimakov. *Metallurg,* Feb. 1936, pages 3-8. In Russian. Au plating and Ag plating of articles measuring 3 x 2 meters did not present any unusual difficulties. They were plated in usual baths after a proper cleaning. Plating was conducted intermittently by removing articles from the bath and wire brushing them. (8d)

Contribution to the Experimental Study of the Influence of the Support or Cathode on the Structure of Electrolytic Deposits Obtained in Aqueous Solution. Albert M. Portevin & Michel Cymboliste. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1211-1218, discussion page 1218. Factors affecting the structure of electrodeposits are discussed. Crystalline continuity between basis metal and electrodeposit depends upon the contact between the electrolyte and the cathode and the rate of inception of crystalline centers. If this is large, in comparison to the number of the crystals of the cathode, the effect of the surface is nil, but if it is small, the number of the crystals of the cathode per unit of surface determines the crystal size of the deposit. 26 references. PRK (8d)

Bright Nickel Deposits (Glanznickelniederschläge) Eugen Werner. *Oberflächentechnik,* Vol. 13, Feb. 18, 1936, pages 40-42. Very bright, hard and dense Ni deposits are obtained with a current density of 1.5 amp./dm.^{2} They are preferably used for very irregular shapes which are also Cr plated. Such deposit cannot be made on Fe unless the surface has been previously highly polished. The additions to a bath for brightness are: agar-agar, dextrine, Turkish red, but at the same time correct conditions of the negative ion distribution and their amount in relation to the positive ions, current density and pH concentration must prevail. Practical conditions are discussed at length. Ha (8d)

Determination of the Phase Structure of Metallic Protective Coatings by Anodic Dissolution. A. Glazunov. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1262-1268. Discussion page 1286. Technique is described for obtaining the thickness of the whole coating and of intermediate layers, and the phases that make up the intermediate layer and thereby, indicate the method used to coat the base metal provided the basis metal is galvanically protected by the coating. 8 references. PRK (8d)



Electrolytic Rhodium Plating; a Promising New Method for Surface Refinement (Galvanische Rhodinierung; ein aussichtsreiches neues Verfahren der Oberflächenveredelung) *Oberflächentechnik,* Vol. 13, Mar. 3, 1936, pages 53-55. With the discovery of a new source of Rh in the Canadian Ni ores, production has increased to about 500 kg. Rh/yr., the present price being 4.50 RM for 1 g. as compared with 3.0-3.50 RM for Pt. Its advantage, even over Ag and Au plating, consists in its high chemical resistance; it is practically not attacked by aqua regia, lyes and salt solutions, and does not tarnish in S-containing atmosphere. Rh reflects the visible light, from 4000 to 7000 A.U. very uniformly, about 79%, while Ag reflects about 92% and Cr only 60-75%. Rh has a very white color and hardness considerably greater than that of Au, Ag, and Ni. It is used for plating jewelry. Rh plating is simpler than Cr plating. The cathode efficiency is 90%, the H development is, therefore, small; no injurious vapors are formed. Pt anodes 100 x 50 mm. and 0.04 mm. thick, in glass tanks are used. The bath operates at 20°-25° C. with a current density of 0.3-0.5 amp./dm.^{2}, at 2-2.5 volts at the start which rises to 3-4 volts towards the finish. The bath contains 2.5 g. Rh/l. and has excellent throwing power. A good, permanent deposit can be made in 3-6 min.; ½ g. Rh is deposited in 3 min. on 1 m.^{2} area. A Rh deposit cannot be removed by chemical or electrolytic methods, it must be polished off; great care in the preparation of the surface to be plated must, therefore, be taken to avoid waste. Electrolytic degreasing in a solution of 300 g. NaOH, 175 g. Na silicate and 15 g. NH_3 in 5 l. at 3-5 amp./dm.^{2} for a few minutes is recommended. Ag and Ag alloys, Ni, Cu, brass, Ni-Ag alloys, Au and the Pt metals can be plated with Rh directly; Cr, Fe, Zn, Sn and their alloys require the use of a suitable intermediary layer. Soldered pieces which are to be Rh plated should be soldered with Ag since Sn solder gives spots in the Rh bath. Detailed information on bath and procedure is lacking. Ha (8d)

Electrodeposition of Tungsten. *Steel,* Vol. 98, Mar. 9, 1936, page 40. Possibilities of electrodeposited W alloys are pointed out by summarizing briefly their properties. Some uses are suggested. MS (8d)

Pitting of Nickel Plate and How to Overcome It. *Steel,* Vol. 98, Mar. 23, 1936, pages 49-50. Easiest and best method of preventing pitting of Ni plate is to filter solution when freshly prepared and also at frequent intervals during its use. It is also important that pH of bath is not permitted to become so low (acid) that large quantities of H_2 are evolved. Agitation of work rod helps to dislodge H_2 bubbles. Addition of 1 pt. of 3% H_2O_2 to every 200 gal. of solution helps to prevent pitting. MS (8d)

Cadmium Plating. W. P. Barrows & K. D. Williams. *Journal American Society of Naval Engineers,* Vol. 48, Feb. 1936, pages 59-67. Typical plating baths of low and high Cd concentration are given and operating conditions indicated. If Cd plated parts are stored without provision for air circulation, a black discoloration occurs by decomposition of salts left on deposit from incomplete rinsing. Cd also corrodes to form a white powder in closed electrical systems at above normal temperatures by the acid gases given off by electrical insulation. Zn plate is free from both of these effects. Test results are summarized comparing the protective effect of Zn and Cd plated on cold rolled S. A. E. 1010 steel for outdoor atmospheric corrosion in various types of atmosphere. In industrial atmospheres Cd has ¾ the protective life of Zn and 90 Zn : 10 Cd alloy deposits have slightly longer life than either Cd or Zn. Other conclusions, 14 in all, are given. Tests for determining thicknesses of Cd and Zn plate are described. It is believed that rising price of Cd, due to extensive use in automotive bearings will increase the use of Zn for protection of ferrous metals. The protective value of Cd and Zn is about equal in most cases for equal thicknesses except where combustion products are present in atmosphere. The value of Zn for preventing attack on Al at a junction with Fe is considered as being equal to Cd plating on the Fe. WB (8d)

The Testing of Electrodeposited Coatings. L. C. Bannister. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 46, June 28, 1935, pages 701-704. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 134L/10. HBG (8d)

Electrodeposition of Zinc and Cadmium on Aluminum and Aluminium Alloys. B. K. Braund & H. Sutton. *Transactions Faraday Society,* Vol. 31, Dec. 1935, pages 1595-1611. Extensive tests were carried out on Zn and Cd plating of Al. The method of electrolytic cleaning that gave the most promising result was anodic cleaning in ammonia solutions. In general, electrodeposits were satisfactory only on plate material. Solutions of Na zincate reacted with Al alloys and deposited an adherent Zn deposit to form an excellent under-coating for further deposition of Zn and Zn could be deposited from sulphate baths of lower pH value on surfaces prepared in this manner. Methods of measuring current distribution in a zinc sulphate plating bath are discussed. 12 references. PRK (8d)

Theory and Practice of Chromium Plating; the Theory of the Mechanism of Chromium Deposition from Aqueous Chromic Acid Solutions (Theorie und Praxis der Verchromung. Zur Theorie des Mechanismus der Chromausscheidung aus wässerigen Chromsäurelösungen) III and IV. N. D. Birükoff & S. P. Makariewa. *Korrosion und Metallschutz,* Vol. 11, Dec. 1935, pages 265-278. Reviews and specifies the effect of physical and chemical factors on Cr deposition, and describes the different ways of formation of a protective layer, increase of Cr_3 concentration and presence of other cations. The principal basic fact in the electrolysis is that one molecule of reduced chromic oxide corresponds to one atom of deposited metal. In the reduction of CrO_3, Cr_2O_3 is first formed and then CrO. In electrolysis of chromic acid in presence of H_2SO_4, the chromic oxide originating at the cathode forms with H_2SO_4 and H_2CrO_4 a soluble salt, $Cr_{2m}(CrO)_{3m-n}(SO_4)_n$, which at higher H_2SO_4 concentration is transformed into $Cr_2(SO_4)_3$. This salt is reduced to chromous oxide which forms the intermediary protective layer and is partly oxidized by chromic oxide and partly reduced to metal. The chromic acid is reduced in the Cr deposition, not cathodically but chemically, so that it does not come into contact with the cathode. H_2SO_4 plays a very important part in the reactions as it forms soluble compounds with chromous oxide. The total reduction, $Cr^{VI} \rightarrow Cr^{III}$ must be proportional to the H_2SO_4 concentration. The complicated conditions are explained in detail, and in particular the importance of the current density. 18 references. Ha (8d)

8e. Metallic Coatings other than Electroplating

Tinning Copper Wire (Kupferdrahtzinnerei) CH. BERNHOEFT. *Zeitschrift für Metallkunde*, Vol. 27, Nov. 1935, pages 264-266. Cu wire which is to be insulated with rubber is first tinned to prevent the reaction of S with the Cu during vulcanization. The imperfect protection sometimes afforded by the Sn coating has been traced to mechanical imperfections in the Sn layer and to impurities in the Sn such as Cu. Contamination of the Sn bath with Cu as well as pin holes and flaws in the deposited layer may be caused by the acid used to clean the wire being carried into the bath. The best practice now calls for a thorough cleaning and drying of the wire before tinning. Of great importance also is the thickness of the Sn coating which may be controlled by adjusting the temperature of the bath, the length of dipping period, and the speed of travel of the wire. Tabular data showing the results obtained under various sets of conditions are presented. FNR (8e)

The Hot-tinning of Copper: the Attack of the Basis Metal and Its Effects. EDWARD J. DANIELS. *Journal Institute of Metals*, Vol. 58, Feb. 1936, pages 117-125 (Advance Copy No. 728). A study was made of the nature and extent of attack of Cu by Sn and solder during hot dipping. It was found that the alloy layer is invariably duplex, and consists of Cu_3Sn and Cu_6Sn_5. This layer breaks up under solvent attack by the Sn or solder and is removed from the basis metal almost as fast as it is formed. Contamination of the bath and coating from this cause increases rapidly with increase in temperature. The smoothness of Sn coatings is influenced greatly by the degree of the contamination and the quality of the basis metal. JLG (8e)

The Development and Control of Spangles on Galvanized Iron. Part 2, W. G. IMHOFF. *Metal Cleaning & Finishing*, Vol. 7, Mar. 1935, pages 121-126. Discussion of effect of steel on spangles. Analysis of steel of good galvanizing properties is given as C .10, Mn .31, S .037, P .07, Si .03, and an inferior galvanizing steel, as C .07, Mn .34, S .043, P .07, Si .016. The inferior steel having lower C is said to be oxidized and therefore a poor base for galvanizing. High Si and high Cu decrease adherence of the galvanized coating. Some causes of small spangles are presence of Mn oxide, slag and Fe oxide (in cast Fe), Al oxide, and segregations. Wrought Fe always galvanizes with small granular spangles. GBH (8e)

Metallizing—Its Scope and Limitations. J. W. HISHON. *Metallizer*, Vol. 5, Jan. 1936, pages 2-5, 15. A resume is given of the history, mechanism and fields of usefulness of metal spraying. The claim is made that metallizing is superior to welding for building up machine elements, since no preheating is required and no warping, distortion or internal stress is imparted. However, it does not add strength and repairing of fractures is outside its scope although some cracks may be repaired by spraying on the pressure side. Tensile strength of a metal is reduced, brittleness, hardness and compressive strength increased by metal spraying. Density is reduced about 10% due to porosity of sprayed metal. Zn, Te-Pb and "chemically treated Al" are recommended as sprayed coatings to protect against corrosion by water, steam, and brine. The deposit efficiency in best metal spraying practice varies from 60% with Pb to 95% with Ni. BWG (8e)

Electric Tinning and Galvanizing Furnaces (Ueber Elektro-Verzinn- und Verzinkungsöfen) H. FINNERN. *Elektrowärme*, Vol. 6, Jan. 1936, pages 27-30. Factors which determine the heat consumption, heat distribution and mechanical operation of tinning and galvanizing furnaces are discussed; operating data for 4 electric tinning installations for a production of 16 to 600 kg. per hr. are given. Ha (8e)

Striations in Tin Coatings on Copper. BRUCE CHALMERS & W. D. JONES. *Transactions Faraday Society*, Vol. 31, Sept. 1935, pages 1299-1303. When Cu is tinned by hot dipping, striations on the Sn coating appear, the appearance of which, under proper illumination, suggests a eutectic. Examination indicates that the pattern is due to alternate areas of Sn with smooth and with mottled or cellular surfaces. The effect is not due to etching. The regular reflections are definitely identified with a reflection from Sn and not from CuSn. The eutectic pattern is most readily produced if the Cu is fairly smooth, thoroughly degreased and adequately fluxed. Temperature changes of the Sn bath are without effect. The rate of crystallization governs the spacing of the striations. The pattern does not depend upon movement of the Sn while still molten. The pattern is not sensitive to normal changes in the Cu content of the Sn bath. The Cu content of the Sn coating was found to be 0.39%. The coating is largely eutectic in structure but contains hypo-eutectic areas. The suggested explanation is that periodic release of latent heat when solidification takes place after supercooling controls the direction of heat flow and also the orientation of the CuSn crystallites in the eutectic. PRK (8e)

The Mellozing Metal-Spraying Process. *Engineering*, Vol. 140, Dec. 27, 1935, page 704. Process developed by Mellowes and Co., Ltd., Sheffield. The metal to be sprayed is melted in a gas-fired crucible and then poured into a container within the metal-spraying pistol. A Bunsen-type burner keeps the metal liquid during the spraying process. The compressed air used for spraying is pre-heated. The thickness of the metal coating is 0.004" with one application and from 8 to 10 ft.^{2} of flat surface can be coated per min. Zn coating is very satisfactory as to corrosion resistance and a pure Sn coating is used for articles coming into contact with foodstuffs. Al-Si alloy is used when heat-resistance is needed. LFM (8e)

Stainless Coatings by an Improved Chromizing Process. *Iron Age*, Vol. 137, Mar. 12, 1936, page 35. Describes a chromizing process developed by Cooper Products, Inc., Cleveland, claimed to be an improvement over previous methods. Originally chromizing was done in H. Improvements consist in the use of ordinary commercial furnaces, chromizing billets or other semi-finished products, and rolling them into strip, sheets, wire, etc. As applied to mild steel, process produces a casing of ferro chrome, 25 to 30% Cr, claimed to have all the desirable properties of stainless steel. Determination of Stresses in a Welded Seam by Means of Photo-elasticity (Sobre la determinacion de tensiones en un cordon de soldadura por la foto-elasticidad) J. BECH ARGELES. *Metalurgia y Construccion Mecanica*, Vol. 2, June 1935, page 6. The author presents a method for calculating the stresses in a weld seam. By means of photographs he shows the application of photo-elasticity in such a determination. FRM (9b)

Notched Bar Testing. S. L. HOYT. *Metals & Alloys*, Vol. 7, Jan. 1936, pages 5-7; Feb. 1936, pages 39-43; Apr. 1936, pages 102-106; May 1936, pages 140-142. Differentiates between notched and impact effects. The notched bar test measures a technological behavior of the material not an inherent material constant. Amount of notch effect to produce brittle behavior varies. Variables of test fall into 2 groups, those relating to geometry of bar and external conditions of test. Square bar seems best shape with 10 mm. a satisfactory size. Smaller radius of notch means lower energy absorption though tougher steels are less sensitive to this effect than brittler steels. Depth of notch is also of greater effect upon brittler steels. Increased striking velocity and lower temperature increase the sensitivity to notched effect more in brittler than in tougher steels. 2 types of fracture are noted in the test: fibrous, in which considerable deformation has taken place around the notch with high energy absorption and cleavage fractures, which are straight across normal to the axis of bar without deformation and with low energy. Increased severity of notch, improper (or overheating) heat treatment and low temperatures tend to produce cleavage fractures. Describes impact test with varying width of specimen (½ to 3 times the thickness) and increased sensitivity of test is gained by increased width of specimen. The utility of notched bar test rests upon its ability to detect unserviceable material. Test can be used to control a number of causes of brittle condition only a few of which can be controlled by other means. 11 such causes are mentioned. 20 references. WLC (9b)

9c. Fatigue Testing

H. F. MOORE, SECTION EDITOR

The abstracts appearing under this heading are prepared in cooperation with the A.S.T.M. Research Committee on Fatigue of Metals.

Endurance Tensile Tests and Endurance Bending Tests with Steel Bars with Flame-cut Faces (Ueber Dauerzugversuche und Dauerbiegeversuche an Stahlstäben mit brenngeschnittenen Flächen) OTTO GRAF. *Autogene Metallbearbeitung*, Vol. 29, Feb. 15, 1936, pages 49-57. Structural elements which have been cut by flame are often required to be machined or smoothed over on the edges (e.g. in the specifications of the German State Railways; American Welding Society). It was investigated how far this is justified, and from the very exhaustive experiments it was found that the strength of flame-cut pieces under often repeated tensile or bending stress was appreciably increased by planing or grinding of the flame-cut faces if the piece was prismatic without holes and machined on all sides. The degree of increase depended on the surface quality. Holes reduced the increase by machining; fracture started at the wall of the hole. Badly, irregularly cut pieces had somewhat lower endurance bending values than neatly, cleanly cut pieces. The annealing of flame-cut pieces increased the endurance resistance under often repeated loads very considerably. In general it was found that flame-cut bars showed endurance tensile and bending strengths which are fully sufficient for many purposes so that they can be used without further machining, especially when the range of variation of load is small and the magnitude of steady load is large. 13 references. Fatigue Testing of Metals (Les essais de fatigue des métaux) ROGER CAZAUD. *Revue de Métallurgie*, Vol. 33, Mar. 1936, pages 164-177. Summary of published data on fatigue testing. Among others the test specimen used by the Services Techniques de l'Aeronautique is described. 20 references. JDG (9c)

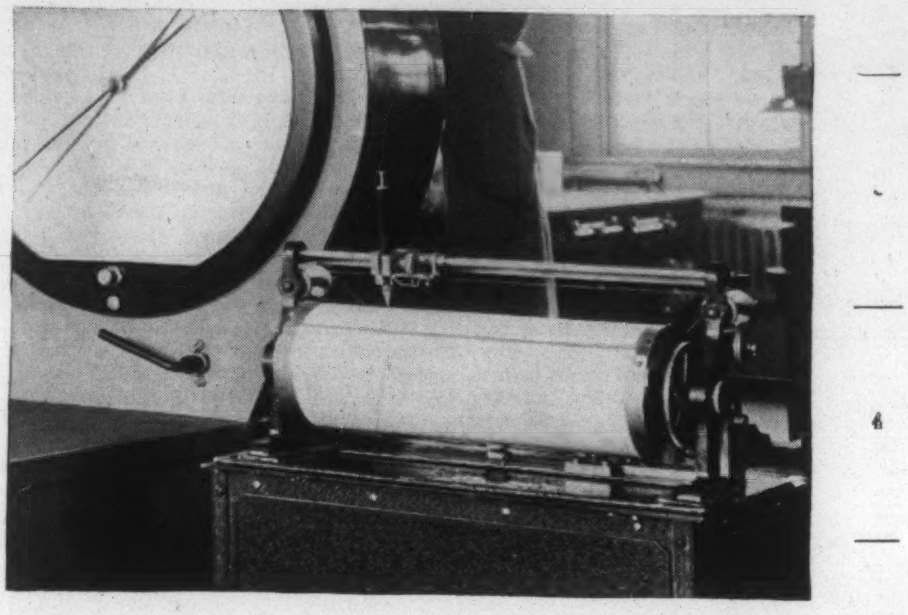
Influence of Concavity in Specimens of Reduced Section on the Endurance Limit in Bending (Einfluss von Hohlkehlen an abgesetzten Wellen auf die Biegewechselfestigkeit) E. LEHR & R. MAILÄNDER. *Archiv für das Eisenhüttenwesen*, Vol. 9, July 1935, pages 31-35. As part of a comprehensive investigation by the Verein deutscher Eisenhüttenleute on the mechanical properties of various C and alloy structural steels the effect of size and shape of fatigue specimens was studied. Three steels, a 0.28% C steel, a 0.32% C, 4.1% Ni, 1.2% Cr steel, and a nitrided steel containing 0.31% C, 2.6% Cr, 0.3% V and 0.3% Mo were tested and the sensitivity to notching determined in various sized specimens whose sections were reduced by means of fillets of differing radii of curvature. In general the larger specimens of both C and alloy steels gave lower endurance values than the smaller specimens and were more sensitive to "notching," as were also the harder steels. See also *Metals & Alloys*, Vol. 6, Dec. 1935, page 501L/10. SE (9c)

Leadership
in TESTING
methods and equipment



The Southwark-Templin Stress Strain Recorder is an instrument for automatic production by electro-mechanical means of full sized stress-strain curves at high magnification at normal testing speed. It has brought about an entirely new approach to materials testing practice.

It has incidentally increased the usefulness of the testing machine for the study of materials in the plastic range, useful in determining susceptibility to development of stretcher-strain in sheet metals used in deep drawing. It has aided in the study of characteristics of ferrous and non-ferrous alloys in different stages of working and heat treating, including elevated temperature tests.

More than that—it has made the testing machine a more vital element in industrial purchasing, manufacturing and sales activities today, because its easily secured, indisputable records, blue printed in as many copies as necessary, are the literal autographs of the materials tested. They may be kept as permanent records of each routine test. They may be supplied with materials sold, in lieu of a test report. They may be used to accompany a proposal in business solicitations. They may be submitted by a purchaser to a supplier accompanying rejected materials.

Typical users of Southwark Stress-Strain Recorders for such purposes are: Union Carbide and Carbon, U. S. Steel Research Laboratories, American Sheet and Tin Plate, Republic Steel, Pittsburgh Crucible, Allegheny Steel, International Nickel, Bethlehem Steel, Carpenter Steel, Midvale, Carnegie Steel, American Steel and Wire, Revere Copper and Brass, Aluminum Company, Barber Asphalt, Ohio Insulator, Corning Glass, U. S. Rubber, Westinghouse Electric, National Cash Register, and others including a long list of U. S. Government Agencies. Bulletin No. 94 describes Southwark Stress-Strain Recorders in detail. A Study of the Fatigue Characteristics of Three Aluminium Specimens Each Containing from Four to Six Large Crystals. H. J. Gough & G. Forrest. *Journal Institute of Metals,* Vol. 58, Jan. 1936, pages 17-40 (Advance Copy No. 722). Specimens were subjected to alternating torsional fatigue. Each was tested at a constant range of applied torque. One specimen remained unbroken and the other 2 fractured. The observed changes in microstructure were related to the crystalline structure as revealed by X-rays and to the applied stressing system. Slip-band distribution of each specimen obeyed very closely the maximum resolved shear stress law, calculated for each crystal as if it alone occupied the entire specimen. Influence of boundaries on slip-band distribution was very slight. Cracking occurred in regions subjected to high values of resolved shear stress. These regions were often in close proximity to a boundary, but results indicated that influence of boundaries was very slight. It was established that fatigue cracking is not initiated at a boundary and that the general course of a crack does not tend to follow a boundary. The fatigue histories of the specimens revealed a fatigue limit, on the basis of 10^8 stress cycles, of about 1 ton/in.^{2} resolved shear stress, which differs but little from that of a single crystal of Al. (Note by H.F.M. It is evident that the fatigue strength of a single crystal or that of a specimen with only a few crystals is much lower than that of a multi-grained specimen of a given metal. This points to the desirability of studying effect of grain size in the range between the ordinary piece of metal, with grains either microscopic in size or barely visible to the unaided eye, and these specimens with only a few crystalline grains. This should not be taken as a criticism of the patient and necessary work of Gough and Forrest). JLG (9c)

Damping Capacity, A Factor in Fatigue. G. R. Brophy. *Transactions American Society for Metals,* Vol. 24, Mar. 1936, pages 154-185. See *Metals & Alloys,* Vol. 6, Dec. 1935, page MA 502L/8. WLC (9c)

Internal Stresses and Their Effect on the Fatigue Resistance of Spring Steels. M. L. Becker & C. E. Phillips. *Iron & Steel Institute,* May 1936, Advance Copy No. 4, 16 pages. The work is part of an extended investigation carried out by the National Physical Laboratory on the effect of surface condition on fatigue resistance of spring steels. Methods of improving fatigue resistance of these steels is a part of the program. Preliminary stress measurements were carried out on a Si-Mn steel, a 0.6% C steel, and a 5% Ni steel case hardened. Quenching from tempering temperatures produced compressive stresses near the surface. Fatigue tests were made on Cr-V and Cr steels to determine the influence of such stresses on fatigue. A few tests were carried out to determine the influence of scragging (permanent deflection by controlled overloading) on the fatigue resistance of spring plates. Fatigue resistance of spring plates can be improved by "temper stressing", that is by quenching in water from the tempering temperature. This improvement is probably due to the presence of compressive stresses near the surface, which cause a reduction in the tensile stress on the tension side of the plates particularly at the roots of surface irregularities. The scragging of springs is beneficial to their fatigue resistance and this again appears to be due to residual compressive stresses in the tension surface. JLG (9c)

Effects of Solutions on the Endurance of Low Carbon Steel Under Repeated Torsion at 482° F. (250° C.) W. C. Schroeder & E. P. Partridge. *Transactions American Society of Mechanical Engineers,* Vol. 58, Apr. 1936, pages 223-231. The steel in a boiler is subject to static stresses and repeated stresses. The latter were investigated at 482° F. It was found that water caused failure more rapidly than air, and NaOH more rapidly than water. NaCl and Na_2SO_4 in water solution had about the same effect as water. Na_2CO_3 and tri-sodium phosphate in water acted the same as NaOH. Addition of Na_2CO_3 or Na_2SO_4 as excess solid to NaOH did not prevent the effect of the latter in repeated torsion tests. Addition of either Na or K chromate or $NaNO_3$ to NaOH solutions prevented the action of NaOH and the endurance of the specimen under test conditions could be brought up to a value at least as high as that for water alone. No relation could be established between endurance of the specimen and surface corrosion or pitting. Ha (9c)

Damage and Overstress in the Fatigue of Ferrous Metals. H. W. Russell & W. A. Welcker, Jr. *American Society for Testing Materials. Preprint* June 1936, 18 pages. Fatigue studies were made on some 12 ferrous metals including specimens of wrought Fe and of cast Fe. The "probable damage line" method developed by French was used and tests were made on both polished and notched specimens. The possibilities and limitations of this method are discussed, and determinations were made of the limits within which no damage was suffered by the metals, as shown by its ability to run subsequently at the virgin endurance limit of the metal for an indefinitely large number of cycles of stress. Some metals showed very low resistance to overstress, while certain notched specimens of wrought Fe were remarkably resistant to overstress, the probable damage line almost coinciding with the S-N diagram. No clear cut relations were found between damage-line test results and the results of other physical tests. However, some insight is given into the mechanism of notch formation and notch propagation. HFM (9c)

The Effect of the Addition of Lead on the Endurance Limit of a Certain Tin-base Bearing Alloy. John N. Kenyon. *American Society for Testing Materials, Preprint* June 1936, 4 pages. Using rotating-beam fatigue tests at 1750 and 3500 r.p.m. the addition of 4% Pb was found to improve slightly the endurance properties of an alloy of 80% Sn, 15% Sb and 5% Cu. After the alloy has been in service a long time a peculiar type of bearing failure sometimes occurs, and some explanation of this is offered. HFM (9c)

Report of the Research Committee on Fatigue of Metals. *American Society for Testing Materials, Preprint* June 1936, 4 pages. A progress report of the cooperative study of X-ray diffraction as a means of detecting incipient fatigue failure is presented as an appendix to this report. X-ray diffraction diagrams give some evidence of the beginning of plastic slip and possibly of the early stages of "creep", but so far have not given any clear cut evidence of the early stages of fatigue cracking. Various developments in fatigue of metals during the past year are very briefly noted, and attention is called to a difference between European and American laboratories in the technique of plotting S-N diagrams. New fatigue testing machines noted included the Haigh-Robertson fatigue machine for testing wire, the Gough machine for simultaneous bending and torsion, and a large fatigue machine of 200,000 lb. capacity built by W. M. Wilson at the University of Illinois. Several high values of endurance ratio (endurance limit: tensile strength) were reported, including one value of 0.8 for cast Fe. HFM (9c)

J. S. MARSH, SECTION EDITOR

Formation of Stable Tungsten Carbide WC in Tungsten Steel. Gisho Kojima. *Kinzoku no Kenkyu,* Vol. 13, Apr. 1936, pages 127-141. In Japanese. η -phase in W steel is fairly stable in low C steel, but in high C steel it readily changes to stable WC on annealing at high temperature. WC is almost insoluble in austenite at temperatures not far above the critical range and consequently the dissolved C in the austenite decreases by annealing. The influence of annealing and added elements such as Ni, Cr, Mn, Si, and Co, on the formation of the stable carbide WC were investigated by measuring Rockwell hardness of quenched W steels. (1.25% C, 10.95% W and 0.82% C, 8.21% W) after annealing at several temperatures for several lengths of time. The most favorable annealing temperature for the formation of the stable carbide is 900°, but by heating to about 1000° for a few minutes the steel can be restored to its original state. The formation of the stable carbide by annealing is markedly retarded by the addition of less than 2% Ni, Cr, Mn, or Si, but on the contrary Co or more than 2% Mn promote its formation. The change of transformation point due to the formation of the stable carbide was also studied by the differential dilatometer. It rises slightly after annealing. KT (10)

Judging Cleanness of Steel by Deep Etching (Beurteilung der Stahlreinheit nach Tiefätzung) E. Houdremont & H. Schrader. *Archiv für das Eisenhüttenwesen,* Vol. 9, Dec. 1935, pages 273-275. To judge the inclusion content of steel by deep etching the sample should be quenched and drawn to eliminate obscuring effects of grain boundary etching. Deep etching then gives indications of P segregation in the longitudinal direction and of sulphides in the transverse direction. On the whole the evaluation of the inclusion content of a steel by deep etching should be checked by other methods. SE (10)

Effect of Mechanical Deformation on Transformation Rate of Polymorphous Metals (Der Einfluss mechanischer Deformation auf die Umwandlungsgeschwindigkeit polymorpher Metalle) E. Cohen, A. T. Cohen-de Meester & A. K. W. A. van Lieshout. *Proceedings Royal Academy of Sciences of Amsterdam,* Vol. 38, No. 4, 1935, pages 377-387. See "Rate of Polymorphous Transformations, III," *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 142L/1. EF (10)

The Metallic State (Consideraciones sobre el Estado Metálico) É. Jimeno. *Metalurgia y Construccion Mecanica,* Vol. 2, Apr. 1936, pages 11-15. The properties of metals as dependent on atomic and molecular arrangement in the structure, differences between crystalline and vitreous phases, plastic properties, and chemical properties as represented in the periodic system are explained. 10 references. On Alpha Martensite in Carbon Steels. Zenji Nishiyama. *Kinzoku no Kenkyu,* Vol. 13, Feb. 1936, pages 37-40. In Japanese. Tetragonal or α martensite was previously proved by the author to be an interstitial solid solution of C in Fe, based on the fact that the axial ratio c/a of the tetragonal martensite increases with the C content. The radius of the sphere of action of Fe and C atoms was introduced into the calculation of lattice parameter and it was found that the calculated and previously observed values were in fair agreement. KT (10)

Grain Size and Grain Shape in Cast Metals (Korngrösse und Kornform in gegossenen Metallen) R. Mitsche. *Berg- und Hüttenmännisches Jahrbuch,* Vol. 84, Mar. 27, 1936, pages 4-13. Processes in production of metallic bodies by melting under different conditions were investigated. Lowest pouring temperatures produce irregular fine grain; increasing casting temperatures produce needle crystals, highest casting temperatures irregular coarse grain. The cooling velocity decreases with increasing temperatures and plays an important part in the formation of the structure; the undesirable needle crystallization can be avoided by casting tests with pure Al and Cu. 23 references. Ha (10)

Tests on the Diffusion of Carbon, Silicon, and Manganese in Solid and Molten Iron (Versuche über die Diffusion von Kohlenstoff, Silizium und Mangan in festem und flüssigem Eisen) M. Paschke & A. Hauttmann. *Archiv für das Eisenhüttenwesen,* Vol. 9, Dec. 1935, pages 305-309. Reproducible results were obtained for the diffusion of C in Fe at temperatures 900°-1250° C. Less reproducible results were obtained for Mn in Fe and the diffusion of Mn in Fe was considerably lower than for C in Fe. Only very approximate values for the diffusion of Si in Fe were obtained. SE (10)

Strength of Alumina Skin and Its Influence on Surface Tension of Molten Al (La Résistance Mécanique de la Peau d' Alumine et son Influence sur la Tension Superficielle du Métal Fondu) Albert Portevin & Paul Bastien. *Comptes Rendus,* Vol. 202, Mar. 23, 1936, pages 1072-1074. Al metal with a skin of Al_2O_3 has a surface tension of 840 dynes/cm.^{2}, while the non-oxidized metal surface has a value of only 420 dynes/cm.^{2} The Al_2O_3 skin has a tensile strength of 2 kg./mm.^{2}, which the authors believe accounts for the higher surface tension effect. FHC (10)

Two-stage Transformation in Iron and Steel. Kanzi Tamaru. *Kinzoku no Kenkyu,* Vol. 13, Apr. 1936, pages 156-160. In Japanese. The so-called two-stage transformations of A_1 and A_3 of Fe and steel were investigated by differential thermal and X-ray analysis. When the annealed specimen was analyzed thermally in a N_2 atmosphere, no heat change other than that due to the normal transformation was observed. When the specimen was heated in H_2 at 900°-1100° for over one hr., small amounts of abnormal heat absorption and evolution were observed, the former at 680° in heating and the latter at 890° in cooling in addition to A_1, A_2 and A_3. When the specimen was heated at 1150° for 4 hr. in high vacuum, H_2 was liberated, and such abnormality was obliterated. X-ray analysis showed that specimens treated in H_2 give broader diffraction lines than those untreated. From these facts author concluded that absorption of H by Fe causes stress in the Fe lattice. When the Fe was cooled from high temperature, a change took place among Fe atoms just before the A_3 transformation, consequently H_2 was liberated. This corresponds to the small abnormal heat evolution at 890° on cooling. The small heat absorption at 680° is considered to be the reverse phenomenon. KT (10)

Diffraction of Slow Electrons on Single Crystals of Zinc (Beugung langsamer Elektronen an Zinkeinkristallen) S. G. Kalaschnikow & I. A. Jakowlew. *Physikalische Zeitschrift der Sowjetunion,* Vol. 9, No. 1, 1936, pages 13-26. In German. The effect of temperature on the diffraction pattern was quantitatively studied and the results are compared with Debye's theory of X-rays. Electron velocities of 6-140 volts were used. The maxima observed are connected with the space lattice of Zn. EF (10)

X-ray Investigations of the Aluminum-lithium Diagram and Structure of the Intermetallic Compound AlLi (Röntgenographische Untersuchungen des Zustandsdiagramms der Aluminium-Lithium-Legierung und die Struktur der AlLi-Verbindung) G. Komovsky & A. Maximow. *Zeitschrift für Kristallographie,* Vol. 92, Dec. 1935, pages 275-283. Al alloys containing up to 20.5% Li were investigated by X-rays. Two phases, α and β, were established. No parameter change of Al due to addition of Li was observed. The solubility of Li in Al drops from 3.5% at 598° C. to 2.2% according to Assmann (*Zeitschrift für Metallkunde,* Vol. 18, 1926). The β phase was found to be the intermetallic compound AlLi which is cubic, has an edge length of 6.37 A.U. and 16 atoms in the unit cell. EF (10)

Nucleus Formation during Recrystallization. II. Nature of Incubation Period (Über die Keimbildung bei der Rekristallisation. II. Die Natur der Inkubationsperiode) M. Kornfeld. *Physikalische Zeitschrift der Sowjetunion,* Vol. 8, No. 5, 1935, pages 533-535. In German. 2 different interpretations of the nature of the incubation period in recrystallizing cold worked metals are discussed critically. It is shown which explanation agrees best with experimental evidence. (See also *Metals & Alloys,* Vol. 6, Apr. 1935, page MA 164R/5; June 1935, page MA 240R/1; Dec. 1935, page MA 504R/3). EF (10)

Kinetics of Recrystallization in Tin, Cadmium and Iron (Kinetik der Rekristallisation bei Zinn, Cadmium und Eisen) M. Kornfeld & F. Sawizki. *Physikalische Zeitschrift der Sowjetunion,* Vol. 8, No. 5, 1935, pages 528-532. In German. Genesis and growth of new crystals in cold worked Sn, Cd, and Fe is analogous to that in Al; i.e., an incubation period delays the formation of crystal nuclei and the latter grow at a constant rate, as found by Karnop & Sachs (*Zeitschrift für Physik,* Vol. 60, 1930, page 646). Recovery takes place before microscopic recrystallization. EF (10)

Theory of the Ordering Processes and of Diffusion in Solid Solutions of Copper and Gold. The Transformation Kinetics in Alloys. Fourth Communication (Theorie der Ordnungsprozesse und der Diffusion in Mischkristallen von Kupfer-Gold. Die Ordnungsumwandlungen in Legierungen. IV. Mitteilung) W. S. Gorsky. *Physikalische Zeitschrift der Sowjetunion,* Vol. 8, No. 4, 1935, pages 443-456. In German. A Cu-Au alloy with 50 at. % Au has an ordered tetragonal lattice below 300° C. The axial ratio a/c depends on temperature, due to degree of order. The kinetics of the process has also been studied at constant temperature, showing that a/c approaches a stable state as an asymptotic function. A theoretical approach to this process of increasing and decreasing order of the lattice is attempted whereby 3 different mechanisms are discussed critically; namely, diffusion of atoms via intermediary lattice positions, shifting of vacant lattice positions, and direct exchange of atoms. None of the hypotheses is in complete agreement with experimental evidence of the author and of Joost (*Zeitschrift für physikalische Chemie,* Vol. 16, Sec. B, 1932, page 123). EF (10)

Influence of Nickel on Solubility Limits of α-Phase of Cu-Al Alloys (Der Einfluss des Nickels auf die Löslichkeitsgrenzen der α-Phase der Cu-Al-Legierungen) V. Gridnew & G. Kurdjumow. *Metallwirtschaft,* Vol. 15, Mar. 6, 1936, pages 229-231; Mar. 13, 1936, pages 256-259. The effect of Ni upon the Cu-rich corner of the Cu-Al diagram was studied by X-rays, microscopic examination, and dilatometric measurement. 2% Ni raises the β-eutectoid from 570° to 605° C. and narrows the α field from 9.8 to 8.6 weight % Al, but no decrease of solid solubility with temperature was found. 4% Ni had no further effect on the eutectoid temperature or high temperature solubility of Al in the α phase. However, a slight decrease of solid solubility with temperature occurs. GD (10)

On the Possibility of Applying the Thomas-Fermi Method to the Problem of Metallic Cohesion. E. L. Feinberg. *Physikalische Zeitschrift der Sowjetunion,* Vol. 8, No. 4, 1935, pages 416-424. In English. Points out that the energy of the crystal calculated on the basis of the Thomas-Fermi method, when expressed as a function of the interatomic distance has no minima, which confirms the independent numerical calculations of Slater and Krutter. This means that the Thomas-Fermi method cannot explain the stability of the crystal lattice. EF (10)

Effect of Oxygen and Nitrogen on the Appearance of Veining in Ferrite (Einfluss des Sauerstoffs und Stickstoffs auf das Auftreten der Aederung im Ferrit) W. Eilender & H. Cornelius. *Archiv für das Eisenhüttenwesen,* Vol. 9, Nov. 1935, pages 263-264. In a series of very pure irons of varying N_2 and O_2 content there was no relation between degree of veining in ferrite and the content of these elements. It was concluded that α-veining resulted from stresses of γ-α transformation. The impurities played only a minor rôle. SE (10)

Should We Modify Our Interpretation of the Fe-Fe_3C Eutectoid Diagram? (L'Interpretation du Diagramme Eutectoide Fe-Fe_3C, Doit-Elle être Modifiée?) P. Dejean. *Journal de Physique et le Radium,* Series 7, Vol. 6, Dec. 1935, pages 525-531; discussion pages 532-536. The experimentally derived diagrams previously presented by Seigle do not seem to have been established under conditions sufficiently reliable to warrant modification of the classic theory of transformation in Fe and steel; the samples used were too small and cooling rates too rapid. More careful investigation shows that (1) the α-γ transformation of pure Fe is not spread, as Seigle claims, between the A_1 and A_3 points but occurs completely at the A_3 point, and (2) pearlite does not vary in composition to the extent maintained by Seigle, but is of reasonably constant composition, and its formation at the Ar_1 point is in complete conformance with the law of eutectoid formation. FPP (10)

Metallographic Applications of Electronic Rays and Their Physical Basis (Le applicazioni metallografiche dei raggi elettronici e le loro basi fisiche) R. Piontelli. *La Metallurgia Italiana,* Vol. 27, Dec. 1935, pages 817-825. First of a series of articles on electron rays. The theory of wave mechanics is briefly reviewed, and the electron microscope and its use are described. AWC (10)

A Classification of the Crystal Structures with Defect Lattices. Lester W. Stock. *Zeitschrift für Kristallographie,* Vol. 93, Mar. 1936, pages 285-311. In English. The "structure theory" requires that each set of equivalent positions be occupied and filled by chemically like particles. Recent crystal structure determinations have shown that for many substances this requirement is not fulfilled ("defect lattice") except for those designated in the paper as ideal solids. Defect lattices show all transitions from an ideal solid in which each particle forms a rigid lattice of its own to a dispersed state in which the lattice of one particle sort is completely destroyed. Structures with defect lattices have been classified on the basis of the manner in which one of these lattices depart from the "structure theory." The lattice of one or more particle sort is either (I) complete or (II) incomplete. One particle sort occupies (A) one set of equivalent positions (B) more than one set of the same coordination number or (C) positions of various coordination number, either (1) alone or (2) in common with other particles. A deformed lattice is classed as the first example of a defect lattice. The various types of lattice disturbances ("Fehlerordnungen") responsible for the electric conductivity and self-diffusion of solids have all been found by X-ray analysis. The positions of the larger symmetrical openings in a cubic body- and face-centered cell are tabulated. EF (10)

System Iron-cobalt-cobalt silicide-iron silicide (Das System Eisen-Kobalt-Kobaltsilizid-Eisensilizid) R. Vogel & K. Rosenthal. *Archiv für das Eisenhüttenwesen,* Vol. 9, Dec. 1935, pages 293-298. The ternary system Fe-Co-Si was studied thermally and microscopically in the region Fe-Co-Co Si-Fe Si and worked out with the aid of 6 sections through the Si end. The compounds Fe Si and Co Si form a continuous series of solid solutions. A ternary compound Fe Co Si is formed. SE (10)

System Iron-aluminum-carbon (Das System Eisen-Aluminium-Kohlenstoff) R. Vogel & H. Mäder. *Archiv für das Eisenhüttenwesen,* Vol. 9, Jan. 1936, pages 333-340. The Fe end of the Fe-Al-C system was studied by means of thermal curves and the microstructure. 6 primary phases forming on cooling were determined as follows: α, γ, ϵ, and δ three component solid solutions; graphite; and the compound Al_4C_3. Sections through the ternary system up to about 30% Al and 2.7% C are shown. SE (10)

System Iron-cementite-manganese carbide-manganese (Das System Eisen-Zementit-Mangankarbid-Mangan) R. Vogel & W. Döring. *Archiv für das Eisenhüttenwesen,* Vol. 9, Nov. 1935, pages 247-252. Diagrams of the systems Mn-Mn_3C and Fe-Fe_3C-Mn_3C-Mn were determined by thermal analyses and microscopic examinations. Mn and Mn_3C do not form continuous solid solutions with a liquidus maximum; instead a transition takes place between 1.5 to 2.9% C. and at higher C contents there is a temperature minimum. A transformation of Mn_3C at 1050° was observed. For the 3-phase system Mn-Fe_3C-Fe up to 60% Mn the diagram resembled that of Fe-Fe_3C; with higher Mn contents the relations were more complicated. SE (10)

Nitrogen Absorption During Grinding of Soft Iron (Stickstoffaufnahme beim Schleifen von weichem Eisen) H. J. Wiester. *Archiv für das Eisenhüttenwesen,* Vol. 9, Apr. 1936, pages 525-527. Microanalyses indicated that the ground surfaces of soft Fe may absorb N_2. The martensitic surface appearance which sometimes forms after grinding may be due to N_2 absorption. Apparently the heating during grinding activates the surface so that it can pick up N_2 from the air. SE (10)

Ideal and Real Crystal. Discussion (Ideal- und Realkristall, Diskussionsbeiträge) *Zeitschrift für Kristallographie,* Vol. 90, Mar. 1936, pages 161-228. Discussion of A. Goetz, W. Kleber, H. E. Buckley & D. Balarew on a previous paper by H. E. Buckley on the "**Mosaic Structure in Crystals,**" pages 161-166. (See also *Metals & Alloys,* Vol. 6, 1935, page MA 117 L/1) Discussion of A. Goetz, E. Orowan & M. J. Buerger on previous paper by M. J. Buerger on "**The Non-existence of a Regular Secondary Structure in Crystals,**" pages 167-173. (See also *Metals & Alloys,* Vol. 6, 1935, page MA 164 L/1) Discussion of D. Balarew, E. Orowan on the previous paper by D. Balarew on "**The Inner Absorption in Salt Crystals,**" pages 173-186. Discussion of A. Goetz on paper by A. H. Jay "**The Thermal Expansion of Silver, Quartz and Bismuth by X-Rays,**" pages 186-187. (See also *Metals & Alloys,* Vol. 6, 1935, page 122 R/8) Discussion of A. H. Fay on previous paper by A. Goetz on "**Group Phenomena in Metal Crystals,**" pages 187-188. (See also *Metals & Alloys,* Vol. 6, 1935, page MA 204 R/6) Discussion of E. Orowan on paper by G. I. Taylor "**A Theory of the Plasticity of Crystals,**" pages 188-191. (See also *Metals & Alloys,* Vol. 6, 1935, page MA 117 L/2) Discussion of D. Balarew, E. Orowan & A. Smekal on paper by A. Smekal "**Contribution to the Theory of Real Crystals,**" pages 191-216, (See also *Metals & Alloys,* Vol. 6, 1935, page MA 296 R/8) Discussion of L. Royer, D. Balarew & G. Kalb on previous paper by G. Kalb "**Vicinal Phenomena and Their Significance for the Symmetry of the Growth of Crystals belonging to Different Crystal Systems,**" pages 216-220. General Discussion to the problem "**Ideal and Real Crystal**" by M. Straumanis, P. Niggli & A. Smekal, pages 220-228.—It is impossible to give an adequate summary of the information, views, hypotheses, experiments, etc. referred to in these discussions. The original text must be consulted. About half of the discussions are in English and the other half in German. EF (10)

The State of the Rare Earth Elements in a Metal Lattice. V. I. Drozzina & R. I. Jaanus. *Physikalische Zeitschrift der Sowjetunion,* Vol. 9, No. 1, pages 72-80. In English. A study has been made of the relation between temperature and magnetic susceptibility of Ce and Pr. Magnetic moment and Curie temperature of Ce are $p = 11.4\ M_W$ and $\Theta = 6°$ K. respectively. The corresponding values for Pr are $p = 16.0\ M_W$ and $\Theta = 2°$ K. A comparison between the magnetic moments found experimentally and those theoretically derived shows that these elements are in the same state when incorporated in metal lattice as in trivalent chemical combinations. EF (10)

New X-ray Camera for Low Temperatures (Eine neue Röntgenkamera für tiefe Temperaturen). Barbara Ruhemann. *Physikalische Zeitschrift der Sowjetunion,* Vol. 7, No. 5/6, 1935, pages 572-582. A new structural principle is incorporated in the vacuum camera described. The sample, but not the film, is placed in a vacuum. Two designs of the camera, suited for different purposes, are discussed and illustrated. A small refrigerating machine, which can be placed easily on any vacuum camera instead of a Dewar vessel, is suited for attaining any temperature down to that of liquid hydrogen and to hold the temperature at ± 0.1°C. during the exposure of several hours. EF (10)

Spectral Emissivities, Resistivity and Thermal Expansion of Tungsten-molybdenum Alloys. P. N. Bossart. *Physics,* Vol. 7, Feb. 1936, pages 50-54. The spectral emissivities of 3 W-Mo alloys were measured directly by optical pyrometry. These were about 120% at 1300° K. to 110% at 2200° K. of the values which may be calculated from the rule of mixtures. For one alloy this result was compared to a similarly determined ratio of measured to calculated resistivities. By Drude's law the square root of the resistivity ratio should be the corresponding emissivity ratio. For temperatures from 1300° K. to 2100° K. the square root of the resistivity ratio was practically constant at 1.215 checking the emissivity ratio of 1.19 at 1300° K. only. The emissivities of W and Mo were measured. For the alloy 46.5 atomic % W both the resistivity-temperature and the thermal expansion-temperature relations were determined. The resistivity relation is compared with those of the constituents and seems to bear out the theory of Bragg and Williams that the extra increase of resistivities at high temperature is due to increased atomic disorder. Atomic Arrangement in Metals and Alloys. W. L. Bragg. *Journal Institute of Metals,* Vol. 56, No. 2, 1935, pages 275-299; *Metal Industry,* London, Vol. 46, May 17, 1935, page 527. **Metals and Alloys.** *Chemical Trade Journal & Chemical Engineer,* Vol. 96, May 10, 1935, page 360. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 75R/5. HBG + MS (10)

Equilibrium Diagram Cu-Sn Alloys (Sur le Diagramme de Solidification des Alliages Cuivre—Étain) W. Broniewski, J. T. Jablonski & St. Maj. *Comptes Rendus,* Vol. 202, Jan. 27, 1936, pages 305-307. Thermal analysis confirmed Cu_4Sn, Cu_3Sn, and Cu_3Sn_2. FHC (10)

Equilibrium Diagram of Cu-Zn Alloys (Sur le Diagramme de Solidification des Alliages Cuivre-Zinc) Witold Broniewski, J. T. Jablonski & St. Maj. *Comptes Rendus,* Vol. 202, Feb. 5, 1936, pages 411-414. Prolonged annealing and improved methods of thermal analysis confirm the existence of the following compounds: CuZn, $CuZn_2$, $CuZn_6$. FHC (10)

Structure of Some Copper Alloys (Sur la structure de quelques alliages du cuivre) W. Broniewski. *Revue de Métallurgie,* Vol. 32, Dec. 1935, pages 649-657. Critical survey of equilibrium diagrams of Cu-Ni, Cu-Ag, Cu-Al, Cu-Zn, Cu-Sn, Cu-Au systems. 40 references. JDG (10)

Kinetic Differences Between Cast and Deformed Material (Kinetische Unterschiede zwischen gegossenem und vorverformtem Material) H. Bumm & U. Dehlinger. *Metallwirtschaft,* Vol. 15, Jan. 24, 1936, pages 89-90. Characteristics which differentiate cast from recrystallized metals are shown by a metallographic study of precipitation of Ag from Cu solid solution containing 6% Ag. Single crystals are formed from the melt and homogenized after making a ball impression in the sample. The area about the impression recrystallizes and precipitation treatments show much more rapid action in this zone. Agglomeration of the Ag precipitate is also more rapid in this area. Differences are attributed to increase of mosaic structure in the recrystallized state. GD (10)

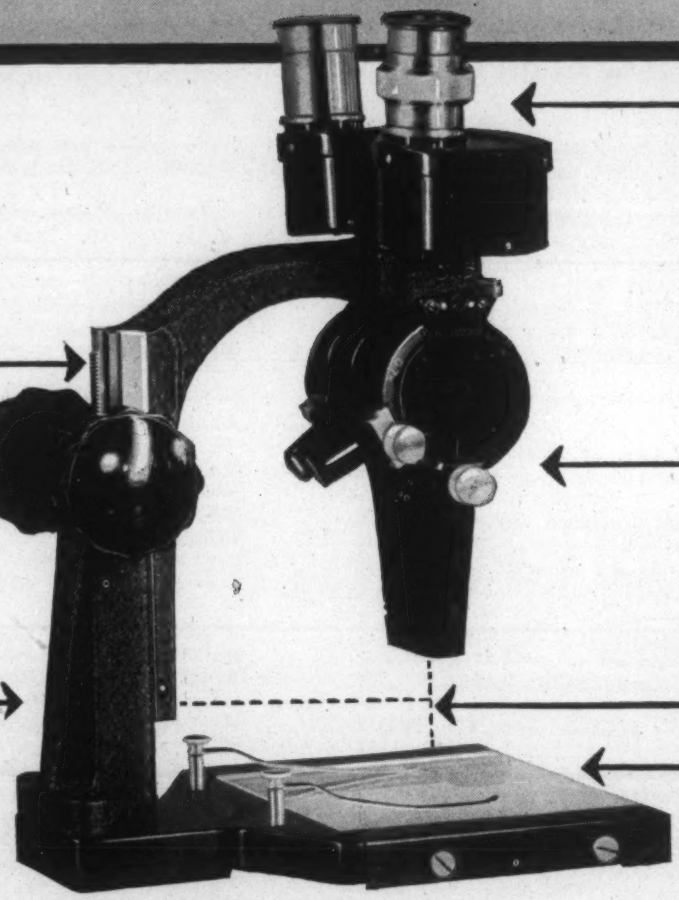
Plastic Deformation and Hardness of Pb (Déformation Plastique et Dureté du Plomb) Marcel Ballay. *Comptes Rendus,* Vol. 202, Jan. 20, 1936, pages 222-224. Severely cold worked Pb of 99.984% purity was held at room temperature for 17 days and the penetration hardness compared with the same cold worked Pb held 1 hr. at 250° C. After 5 mins. application of the load, the Pb annealed at 250° C. appeared slightly harder than the Pb held at room temperature for 17 days. FHC (10)

Problem of Gas in Metals (Le Problème des Gaz dans les Métaux) G. Chaudron. *Usine,* Vol. 35, Jan. 30, 1936, page 37. The various forms in which gases can be retained by metals are classified: (1) Gases retained by adsorption, which decrease with temperature, this is noticeable only for CO. (2) Gases retained mechanically as inclusions, due either to sudden change of solubility of the gas because of temperature difference or of addition of metal (e.g. Mn in Al), or of reaction in the metal, e.g. solidification, reaction of C with FeO. (3) Gases retained in combination, e.g. Fe nitride in isolated pearls. The conditions under which these 3 forms occur are discussed and illustrated. Ha (10)

The Mechanism of Precipitation (Über den Verlauf Ausscheidungen) U. Dehlinger. *Zeitschrift für Metallkunde,* Vol. 27, Sept. 1935, pages 209-212. With discussion. Transformation and precipitation processes may be divided into 2 classes: (a) in which the transition from the initial to the final lattice is sudden and complete, and (b) in which the change of lattice type is gradual. The precipitation of Ag from Cu in cast single crystals and polycrystals is of the (b) type, but if the alloy has been worked and recrystallized the process is of the (a) type. Experiments have shown that particles of Ag in the cast material do not act as centers for reaction. The author proposes that such randomly distributed aggregates redissolve in favor of more effective nuclei, which form at the boundaries of mosaic blocks. The wider spacing of the mosaic in cast metal thus accounts for the slower rate of precipitation. The first material precipitated thus forms a skin over the mosaic blocks, which agglomerate on further annealing. This conception affords an explanation of the 3 hardness maxima found experimentally. The precipitation of Ag is autocatalytic in recrystallized samples, but the exact kinetics of this process is not clear. GD (10)

Nitrogen Content and Abnormality of Sintered Carbonyl Steel (Stickstoffgehalt und Gefügeanormalität der Sinterkarbonylstähle) H. Cornelius & H. Esser. *Archiv für das Eisenhüttenwesen,* Vol. 9, Jan. 1936, pages 367-368. Sintered carbonyl Fe was found to contain as much as 0.02% N_2. This N_2, however, did not appear to be the cause of the abnormal structure. SE (10)

INCREASING THE *Usefulness* OF AN OLD FAVORITE



An extra long rack and pinion gives complete and positive adjustment.

Large Bakelite focusing buttons permit more delicate focusing adjustment.

Stand is heavier and more rugged throughout.

Individual focusing tube to compensate for variation in user's eyes.

Revolving drum nosepiece tried and proved in actual service.

Distance from Optical Axis to arm is 3½".

Glass Stage mounted flush with metal supports to give larger working area.

In addition to the new features illustrated above, the new B & L Wide Field Binocular Microscope retains the exceptionally wide field—the pronounced three dimensional effect—and the erect and unreversed image—that have made it such a useful instrument for metallurgists, laboratory workers and shop foremen.

Its new features still further increase its desirability for examining roll laps, pipe, seams, scale, surface pitting, segregation and many other characteristics. Its range of magnification from 7X to 150X is completely adequate for most needs. The perfection of the Bausch & Lomb objectives and optics makes its use a continual pleasure. Its price is so reasonable that one or more of these instruments should be in every laboratory. The latest literature will be sent promptly on request. Send the coupon to Bausch & Lomb Optical Co., 634 St. Paul Street, Rochester, N. Y.

Contribution of Metallography to Mechanical Engineering (Il Contributo della Metallografia alla Meccanica) G. GUZZONI. *Industria Meccanica,* Vol. 18, Jan. 1936, pages 6-8. Appraisal is made of important progress in mechanical engineering due to more intimate knowledge of properties of metals gained by metallography, and exemplified by an improved cast Fe produced by Ford.
Ha (10)

Aluminum-boron System (Beitrag zur Kenntnis des Systems Aluminium-Bor) W. HOFMANN & W. JÄNICHE. *Zeitschrift für Metallkunde,* Vol. 28, Jan. 1936, pages 1-5. Constitution of Al-B alloys up to 4% B was studied by microscopic, X-ray diffraction, and polarization-microscopic methods, wherefrom a diagram differing widely from that of Haenni (Revue de Métallurgie, Vol. 23, 1926, page 343) was derived. Compounds AlB_2 and AlB_{12} were identified. Both appear as thin hexagonal plates in the microstructure. AlB_{12} undergoes a peritectic reaction with the liquid (estimated composition 4% B) at about 1350° C. to form AlB_2 and liquid. The liquidus curve drops sharply from AlB_2-AlB_{12} peritectic to a reaction (peritectic or eutectic) at a temperature near the melting point of pure Al and at a composition between 0 and 0.2% B. No solid solubility of B in Al could be detected by lattice measurements of an alloy quenched from 600° C. The compound AlB_2 is hexagonal with one molecule per unit cell. Al atoms occur at 0, 0, 0 and B atoms at ⅓, ⅔, ½, ⅔, ⅓, ½. The lattice dimensions are $a = 3.00$ A.U. and $c = 3.24$ A.U. A third (hexagonal?) phase of unknown composition was observed growing upon and taking its orientation from the AlB_2 plates. 13 references.

The Thickness of the Amorphous Layer on Polished Metals. H. G. HOPKINS. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1095-1101. Using Au with the surface ground smooth by light rubbing on 000 emery paper and final grinding of 4 minutes on 0000 emery paper—2 minutes in each of 2 directions at right angles—15 minutes polishing on clean chamois leather was sufficient to induce the polished layer. The surface structure of the specimen was investigated by electron diffraction after the manner of G. P. Thomson. The surface was removed by sputtering under standardized conditions to determine the depth of the polished layer. The thickness of the Beilby layer was found to be about 30 A.U. over much of the surface. There was a general increase in crystal size below the polished surface. 14 references.

Study of Certain Aluminium-chromium Alloys. SOJI HORI. *Research Reports of the Sumitomo Metal Industries,* Vol. 2, Dec. 15, 1935, pages 351-372. In Japanese. Equilibrium diagram of Al-Cr system in the range 0-50% Cr was determined by thermal and microscopic analyses. 3 peritectic reactions were ascertained to take place at 1018°, 803° and 660° C., through which Al_2Cr, Al_4Cr, and a solid solution are formed, respectively. The limit of solid solubility of Cr in Al at 640° was determined to be 0.67-0.80%, and the value is constant as the temperature falls down to 470°. Rolled sheets of the alloys, containing up to 1.6% Cr. were subjected to mechanical and corrosion tests after heat treatments. The tensile strength increases slightly as Cr content increases. The alloy containing about 0.7% Cr showed remarkably high tensile strength on annealing. The phenomenon was assumed to be due to its higher recrystallization temperature. The alternate wet and dry corrosion test was carried out by use of artificial sea water for a month. The annealed alloy containing about 0.7% Cr was found to resist corrosion more than the annealed pure Al.
TS (10)

Roentgenographic and Electrical Investigations of the Cu-Au System (Röntgenographische und elektrische Untersuchungen des Cu-Au Systems) C. H. JOHANSSON & J. O. LINDE. *Annalen der Physik,* Series 5, Vol. 25, Jan. 1936, pages 1-48. In the 50% range, an ordered phase with 40 atoms in the elementary cell was found; the distribution of the atoms is rhombic. This phase CuAu II is obtained after tempering the alloy for a long time in the ranges of concentration of 36-47 and 53-65% Au at 200°-400° C., tempering under the same conditions in the concentration range 47-53% Au produces the previously known tetragonal phase CuAu I. Quenching this phase from 410°-420° C. changes it to CuAu II. The reasons for this transformation are discussed and ascribed to lattice deformation of not ordered phases. Concentrations of 65-80 at. % show cubic structure. The electric resistances have been determined for the whole system CuAu under different heat treatments. 44 references.
Ha (10)

The Constitution of the Tin-rich Antimony-tin Alloys. D. HANSON & W. T. PELL-WALPOLE. *Journal Institute of Metals,* Vol. 58, Feb. 1936, pages 79-90 (Advance Copy No. 725); *Technical Publications, International Tin Research & Development Council,* Series A, No. 31, 1936, 12 pages. Previous work on the Sn-Sb system is reviewed. Constitution of alloys up to 14% Sb was investigated by thermal and microscopal analyses, and electrical resistivity measurements. The portion of the liquidus investigated consists of 2 branches, the first corresponding to the separation of the Sn-rich α phase and the second of the cuboid δ phase. A peritectic occurs at 246° C. between δ and the liquid containing 9% Sb to form α containing 10.5% Sb. The solidus of the Sn-rich phase was determined by thermal and microscopical methods. The solubility of Sb in Sn decreases from 10.5% at 246° C. to 4% at 190° C. and to 3.5% at 100° C. The form of the solubility curve suggests that the mechanical properties of these alloys which form the base of the Sn-rich bearing metals might be sensitive to heat treatment. Their response to heat treatment is being investigated. JLG (10)

Copper-nickel-iron System (Das System Kupfer-Nickel-Eisen) W. KÖSTER & W. DANNÖHL. *Zeitschrift für Metallkunde,* Vol. 27, Sept. 1935, pages 220-226. Ternary diagram is developed from published data and new measurements of the magnetic susceptibility, electric conductivity, and thermal properties of the system. Electrolytic Cu and Ni and Armco Fe were used, the principal impurities being small amounts of C, Si, and Mn. The alloys showing the γ to α Fe transformation lie within the line drawn from the 28% Ni point on the Fe-Ni side to the Cu corner. The miscibility gap of the Fe-Cu system is diminished by additions of Ni being closed at 1220° C. by 27% Ni and at 25° by 82%. The nodal directions in the miscibility gaps and the decomposition limits are determined from Curie points and conductivity measurements.

11. PROPERTIES OF METALS AND ALLOYS

Review of Physical Principles of Metal Plasticity (Ein Ueberblick über die physikalischen Grundlagen der Metallplastizität) H. SCHLECHTWEG. *Technische Mitteilungen Krupp,* Vol. 4, Mar. 1936, pages 29-38. The problem of the mechanism of polycrystalline materials and their behavior under stress has been treated from 3 points of view: (1) by neglecting the structure, the material is considered as a continuum; this permits developing theories useful in application of metals by the engineer. (2) The mechanistic behavior of the monocrystal is considered and explained by classical physics, and (3) the modern atomistic theory is applied to explain, with the help of quantum mechanics, the behavior of metals. Examples are treated under the 3rd point of view explaining creep, plasticity, formation of alloys, and movement of heat in the crystal lattice, and an attempt is made to calculate the properties of a multi-crystal from those of a monocrystal. The theory of G. J. Taylor for the propagation of a plastic gliding is explained. 60 references.

The Solubility of Lanthanum in Mercury from 0° C. to 50° C. W. GEORGE PARKS & JOSEPH L. CAMPANELLA. *Journal of Physical Chemistry,* Vol. 40, Mar. 1936, pages 337-342. La amalgams were prepared by direct heating of the metal with Hg and by the electroysis of $LaBr_3.H_2O$ in absolute ethyl alcohol. The solubility of La in Hg is reported at 0°, 12.5°, 25°, 37.5° and 50° C. In the temperature range from 0° to 50° C. the solubility is expressed by the equation.

$$\log N_2 = \frac{-1020}{T} - 0.4575$$

A brief discussion of the problem affecting the determination of the solubility of sparingly soluble metals is given. The low solubility of La in Hg indicates that La has a rather high internal pressure, approximately the same as that of Bi. From the general behavior of La amalgam it is assumed to be unsuited for precise e.m.f. work without considerable difficulty. 27 references.

Experiments on Supraconductive Tantalum. K. MENDELSSOHN & J. R. MOORE. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Vol. 21, Mar. 1936, pages 532-544. The importance of magnetic threshold values in supraconductors, i.e. the magnetic field strength just sufficient to destroy supraconductivity, with regard to the thermodynamical behavior of the metal is explained. The threshold curves and magnetic penetration curves coincide for most metals with low melting points, but in Ta a discrepancy exists which is explained by thermodynamical behavior of small supraconductive regions. 11 references.

Nickel—Chromium Heat Resisting Alloys—Properties and Production Methods. A. M. C. MURPHY. *Metal Industry,* London, Vol. 47, Oct. 18, 1935, pages 387-390, 402. Discusses alloys of Ni, Cr, and Fe used in resistance materials. The 80 Ni-20 Cr received major consideration and its properties are compared with those of the cheaper alloy 65 Ni, 20 Fe, 15 Cr. Production of the 80/20 material is considered one of the most difficult metallurgical tasks of the present time. Careful attention is necessary from the charging of the melting furnace through to the last pass of the wire. Melting, casting, forging, hot-rolling, wire-drawing and annealing are considered. The article is illustrated by binary and ternary diagrams, tables and micrographs.

The Absolute Measurement of the Viscosity of Liquid Tin. A. J. LEWIS. *Proceedings, Physical Society,* Vol. 48, Jan. 1936, pages 102-110. Includes discussion. The viscosity of molten Sn between 235° and 330° C. in an atmosphere of H was determined by observing the time taken for a known volume to flow through a vertical capillary tube under a known pressure difference. Values ranged from 0.0195 poises at 235° C. to 0.0160 poises at 330° C. These agree well with the measurements made by Stott with a rotating disc and by Sauerwald and Töpler by the capillary flow method.

Aluminum Alloys—Patent List (Aluminium-Legierungen, Patentsammlung) A. Grützner & G. Apel. Supplement to section on aluminum in Gmelin's Handbuch der anorganischen Chemie. Part 2. Verlag Chemie, Berlin, 1936. Boards, 7 x 10 inches, pages 343-868. Price 54 RM.

Similar to part 1, issued earlier in 1936 and reviewed in *Metals & Alloys*, Vol. 7, May 1936, page MA 256R/9. This completes the listing of all patents on Al alloys in the chief industrial countries up to May 1935. A feature of this volume is a list of trade names or numbers by which commercial alloys are designated by various makers and the composition of the alloys compiled by A. von Zeerleder. This occupies 14 pages and resembles Campbell's A.S.T.M. list. This list is an extremely useful one. H. W. Gillett (11a) -B-

Aluminum Handbook (Aluminium Taschenbuch) 6th Edition. Aluminium-Zentrale G.m.b.H., Berlin, 1936. Paper, 4½ x 6½ inches, 377 pages. Price 4 RM.

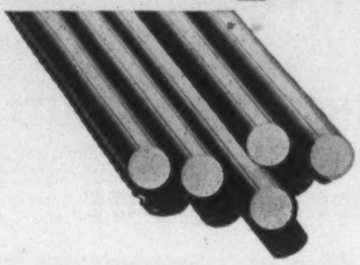
Aluminium Taschenbuch, which is now in the sixth edition, is a handbook published for the information of German users of Al. This volume represents a 50% increase in pages over the previous edition. It covers a wide variety of subjects, such as historical and statistical data on Al, the composition and properties of commercial Al alloys, the physical testing and chemical identification of Al alloys, data on casting, cold working and heat treatment, methods of machining and joining, surface treatment and chemical properties. It includes an extensive section on the use of Al in the electrical industry, and a variety of tables of general interest to chemists and engineers. The reader of German should find this Handbook very useful, for example, in finding the approximate chemical composition of Al alloys known only by their commercial names. The tables of properties of Al alloys are quite extensive and detailed. While the treatment of the subjects is generally limited by the size of the book, it contains a surprising amount of information, most of which appears to be up-to-date and well selected. J. D. Edwards (11a) -B-

Magnesium and Ultra Light Alloys (Le Magnésium et les Alliages Ultra-Légers) Paul Bastien. *La Technique Moderne*, Vol. 27, Nov. 1, 1935, pages 702-708. First section studies chief sources of supply. Industrial method for obtaining and purifying Mg are reviewed. Second section is devoted to following subjects: (A) Physical and chemical properties of Mg. (B) Various types of ultra light alloys actually used. Pure commercial Mg gives as cast: Tensile 10-12 kg./mm.^{2}, elongation (on 100 mm.) 6%; as drawn wire: Tensile 18-22 kg./mm.^{2}, elongation (on 100 mm.) 8-12%. Equilibrium diagrams of binary systems: Mg-Zn, Mg-Al, Mg-Cu and ternary alloys: Mg-Al-Zn and Mg-Al-Cu are given and discussed. Commercial alloys are: (1) Mg-Al alloys containing 4-6% Al which are known as Dow-Metal and give as cast in sand: Tensile 15-17 kg./mm.^{2}, elongation (on 100 mm.) 4-5%, Brinell 45; as cast in metal mold: Tensile 16-18 kg./mm.^{2}, elongation (on 100 mm.) 5-8%, Brinell 55; as drawn wire: Tensile 27-29 kg./mm.^{2}, elongation (on 100 mm.) 15-18%, Brinell 50. (2) Mg-Zn and Mg-Al-Zn which are known as Elektron alloys and are much used in aircraft engineering. (3) Mg-Cu and Mg-Al-Cu alloys which comprise 2 classes, the first with Al + Cu less than 6% which are somewhat similar to the above but with a thermal conductivity slightly higher, the second with Al + Cu more than 8% and less than 15% which have a high thermal conductivity making them particularly suitable for piston manufacture. Cu reduces corrosion resistance of Mg. In Mg alloys containing more than 8% and less than 15% Cu + Al, those containing 8-12% Cu with little Al are forgeable whereas those containing 8-12% Al with little Cu are not forgeable. Thermal expansion of Mg is given as 25.8 x 10^{-6} (c.g.s. units) and that of common alloys as 24-28 x 10^{-6} depending on the composition. FR (11a)

Aluminum-Magnesium Alloys (Alliages aluminium-magnésium) Pierre Vachet. *Revue de Métallurgie*, Vol. 32, Dec. 1935, pages 614-626. Accurate space lattice determinations showed that annealing for 16 hours retains in solution about 8% Mg. Drawing quenched alloys precipitates the excess of Mg above 8% in 2 hrs. at 200° C., but 24 hours are required to bring it down to 4.5%. Only alloys in solid solubility range were investigated, though low rate of diffusion almost always results in β phase precipitation. Dilatometric investigation indicated a practical similarity between curves obtained with alloys containing more than 11% Mg and no Mn and 9% Mg with 0.5% Mn both in quenched and annealed state. Under these limits there are observed two anomalies which cannot be explained, unless they are allotropic transformation of β phase. For alloys containing less than 8% Mg quenching and annealing treatments produced the same properties. Heating cold worked metal between 150° and 450° C. softened it in 5 minutes. When Mg is above 8% precipitation of β phase after treatments reduces ductility of the alloys. Aging following quenching from 450° C. does not occur when Mg is below 8%. With Mg above this content aging does not take place at room temperature or at 75° C., is slow at 150° C., but reasonably fast at 200° C. Alloys age proportionally to the Mg content. Impact values are unusually high for light alloys, 6-9 kg.-m/cm.^{2}, and they are improved by quenching. Fatigue testing gave fatigue limit of about 12 kg./mm.^{2} for 12% Mg alloy. Salt spray corrosion resistance of the alloys is good and is improved by treatments retaining β phase in solution. Mn addition does not have any effect on corrosion resistance. Sand cast Al-Mg alloys have tensile strength of 16-20 kg./mm.^{2}; their elongation drops from 13% for a 3% Mg alloy to zero for 12% Mg alloy. Quenching them in oil at 425° C. gradually increases tensile strength from 16 to 32 kg./mm.^{2}. Their elongation passes through a minimum at 8% Mg content and reaches 15-20% for a 12% Mg alloy. Addition of 0.5% Mn increases tensile strength by 2-3 kg., the effect being more pronounced with higher Mg content. A 0.5 Mn, 12% Mg and 87% Al alloy has the best casting properties of the series and after quenching has a tensile strength of 33 kg./mm.^{2} with an elongation of 12%. These properties can be obtained when the molten metal is protected from oxidation and nitriding by a flux such as carnalite and from the action of the moisture in the sand. In the latter case addition to sand of boric acid is quite beneficial. For heat treating a heating for 24 hours at 425° C. and quenching in oil is recommended. JDG (11a)

Elastic Secondary Effects in Arranged Copper-Gold Alloys. Elastic Hysteresis of the First Order (Die elastische Nachwirkung in geordneter Kupfer-Gold Legierung. Elastische Nachwirkung erster Art) W. S. Gorsky. *Physikalische Zeitschrift der Sowjetunion*, Vol. 8, No. 5, 1935, pages 562-571. In German. The object of this investigation was to check on the previously advanced theory of the author by determining the elastic hysteresis in the arranged Au-Cu lattice. In polycrystalline material a hysteresis of 60-100% of the elastic deformation could be found as of the effects was close to the predicted ones. The speed of this process increases with rising temperatures. EF (11a)

Headquarters for



Alloy Steels

Immediate Stock Shipment

The newer, finer, money saving alloy steels are immediately available from Ryerson stocks. All major S.A.E. specifications, Tool Steels, Stainless and Heat Resisting Steels are carried in a full range of sizes. All other steel and allied products—the most complete stocks in the country are also carried to meet your requirements. Whether you need a few pounds or a carload, your order will have our personal attention and will be shipped at once.

Write for the Ryerson Stock List—Key to Immediate Steel.

Joseph T. Ryerson & Son, Inc., Chicago, Milwaukee, St. Louis, Cincinnati, Detroit, Cleveland, Buffalo, Philadelphia, Jersey City, Boston.

RYERSON

ULTRA-CUT STEEL

Fabricated from ¾" round Ultra-Cut with 16 double threads and ⅛" lead. Meets a machining problem better than SAE1112.

Specify this *High Speed Screw Stock of Industry* for your automatic screw machine department—and let it prove its economy by increasing your production. Ask for ULTRA-CUT FOLDER No. 3-M.

Will see you at the American Metal Exposition, Cleveland, Ohio, October 19 to 23. Space F-20.

HARVEY, ILL. *Sales Offices in all Principal Cities* BUFFALO, N.Y.

OFHC
REG. U.S. PAT. OFF.

OXYGEN-FREE HIGH CONDUCTIVITY

A Superior Copper
for All Purposes

OFHC Copper conforms to the A.S.T.M. Specification for electrolytic copper wirebars, cakes, etc., B5-27 with regard to metal content and resistivity, and is free from cuprous oxide.

OFHC Copper is characterized by its freedom from casting defects and its bar-for-bar uniformity. Its freedom from oxygen results in great ductility and toughness as evidenced by its high reduction of area and resistance to impact.

OFHC Copper withstands more working in hard condition when tensile strength is greatest, making it especially suited for products subjected to severe fabricating or service conditions.

Copies of a schedule of weights and dimensions of **OFHC** wirebars, cakes and billets, and a booklet containing technical information will be gladly furnished upon request.

Standards for Lead, Zinc, Tin and Light Metal Die Casting Alloys (Normblattentwürfe für Blei-, Zink-, Zinn- und Leichtmetall-Spritzgusslegierungen) Deutscher Normenausschuss, Fachnormenausschuss für Nichteisen-Metalle. *Zeitschrift für Metallkunde,* Vol. 27, Oct. 1935, pages 245-248. In the form of tables the standard compositions, limits of impurities, mechanical properties, casting data, standard test requirements, and typical uses of the German die casting alloys of Pb, Zn, Sn, Al and Mg are given. FNR (11a)

Duralumin and Related Alloys Properties and Heat Treatment Procedure. HAROLD SILMAN. *Metal Industry,* London, Vol. 47, Aug. 30, 1935, pages 199-201. The discovery of duralumin, its early history and development are briefly outlined. The mechanism of age-hardening is discussed. The 3 stages in which duralumin alloys are treated are summarized as: (1) solution heat treatment, whereby the soluble constituents are brought into solid solution; (2) rapid quenching, for the purpose of retaining these constituents in a metastable, supersaturated solution; and (3) aging, during which the dissolved compounds are gradually precipitated. The hardness of the alloy is dependent upon the state of division of the precipitated particles. Certain precautions relative to temperature control and treatment of the nitrate-bath, used in solution heat treament, are included. The composition of "standard" duralumin is given as 4% Cu, 0.5% Mg, 0.5% Mn, together with the Fe and Si normally present in commercial Al. The effects of variation of the Cu-content, of additions of Si, Mn, and Mg are indicated. The methods of heat treatment used for these modified duralumin alloys, the characteristics of these alloys and commercial applications are briefly discussed. Mention is made of the "Y" alloy, consisting of Al plus 4% Cu, 2% Ni, and 1.5% Mg, its advantages, method of heat treatment and commercial applications. HBG (11a)

The Free Energies and Vapor Pressures of the Alkali Metals. A. R. GORDON. *Journal of Physical Chemistry,* Vol. 4, Feb. 1936, pages 100-102. The free energies of the diatomic alkali vapors are calculated from spectroscopic data and the equilibrium constants for dissociation into the monoatomic form are computed. With the aid of these constants, equations are deduced from the observed vapor pressures obtained by various investigators which give the partial pressure of atoms and molecules in the saturated vapors for temperatures up to the normal boiling point. In the case of Na and K, the entropy of the solid metal is computed from the vapor pressure equation and is compared with that predicted by the third law of thermodynamics. EF (11a)

Precipitation-hardenable Bronzes of a Copper-nickel-tin Base (Ueber aushärtbare Bronzen auf Kupfer-Nickel-Zinn-Grundlage) E. FETZ. *Giesserei,* Vol. 22, Dec. 6, 1935, pages 604-611. See *Metals & Alloys,* Vol. 7, Apr. 1936, page MA 201L/5. Ha (11a)

Characteristics of Nickel-Silver Alloys—Working Properties and Applications. *Metal Industry,* London, Vol. 48, Jan. 3, 1936, pages 3-4. Adhesion of Two Metal Surfaces in Vacuum and the Lowering of Adhesiveness by Certain Gases (Ueber das Haften zweier Metallflächen aneinander im Vakuum und die Herabsetzung des Haftens durch gewisse Gase) R. HOLM & B. KIRSCHSTEIN. *Wissenschaftliche Veröffentlichungen aus den Siemens-Werken,* Vol. 15, Dec. 31, 1935, pages 122-127. A measuring method was developed by which the adhesion between 2 metal surfaces could be measured in terms of the angle by which the specimen must be inclined before sliding starts. In some cases even a vertical position did not cause sliding; this was called sticking, in opposition to adhering when sliding takes place. Ni-Ni, Pt-Pt, Ni-Pt and graphite-Ni were used. In a vacuum and chemically inert gases (N_2 and Ar), the annealed metals stick strongly together. In presence of O, H and vapors of benzene, toluol and alcohol, sliding takes place; the respective angles were determined. The reason for sliding is seen in the formation of a film on the metal, in the absence of which sticking may take place. Ha (11a)

Theory of Elastic Secondary Effects in Solid Solutions of Random Atom Distribution. Elastic Secondary Effects of Second Order (Theorie der elastischen Nachwirkung in ungeordneten Mischkristallen. Elastische Nachwirkung zweiter Art) W. S. GORSKY. *Physikalische Zeitschrift der Sowjetunion,* Vol. 8, No. 4, 1935, pages 457-471. In German. It is shown that the existing theories interpreting elastic hysteresis on the basis of uneven plastic deformation are not completely satisfactory. A new theory is advanced ascribing the hysteresis phenomena in solid solutions to a combined effect of diffusion and uneven stresses. The 2 cases of solid solutions, i.e. "penetration solution" and "subtraction solution" are investigated. It is shown that the elastic hysteresis can be increased up to 50% of the elastic deformation. Evaluating the rate of this process, it is demonstrated that secondary effect becomes extremely slow in single crystals with thicknesses of from 10^{-2} to 10^{-4} mm. An attempt is made to interpret the hysteresis in polycrystalline metals and alloys on the basis of diffusion. EF (11a)

Mechanical Properties of Tin Base Alloys (Propriétés mécaniques des alliages à base d'étain) D. J. MACNAUGHTAN & B. P. HAIGH. *Revue de Métallurgie,* Vol. 33, Jan. 1936, pages 7-13; *Technical Publications of the International Tin Research & Development Council,* Series A, No. 26, 1935, 12 pages; *Metal Industry,* London, Vol. 47, Nov. 1, 1935, pages 441-444, 448. This paper was presented to the International Congress of Mining, Metallurgy and Applied Geology Oct. 24, 1935. The authors state that while in some circumstances the low mechanical strength and high ductility of tin are an advantage, in other cases, as in pewter, pipes that must withstand pressure, solder and bearing metals, reenforcement by some other method is necessary. In the preliminary work on bearing metals undertaken for the International Tin Research and Development Council, a study has been made of the mechanics of the combination of layers of soft white metal on rigid liners. The work began by a study of the physical properties of various Sn-alloys for the purpose of selecting the most promising materials to be tested later in conjunction with suitable backing material. The methods of testing used are discussed. They include tension and compression testing, hardness, fatigue tests, and creep at elevated temperatures. The influence of time in "creep" and "self-annealing" is of major importance in the practical use of white metal alloys. In the study of the white metals, in direct contrast to the methods usually used in testing other metals, a technique was developed in which creep and self-annealing are revealed in their full importance. The results obtained in a systematic study of the effect of additions of different alloying elements on the mechanical properties of tin are considered. 5 references. JDG + HBG (11a)

Plastic Deformation and Age-Hardening of Duralumin. P. L. TEED. *Engineering,* Vol. 141, Mar. 20, 1936, pages 320-321. See *Metals & Alloys,* Vol. 7, Apr. 1936, page MA 202R/10. VSP (11a)

V. V. KENDALL, SECTION EDITOR

Cooperative Study of a Stable 18 Cr 8 Ni Steel Without Stabilizing Additions. Progress Report. *Transactions American Society of Mechanical Engineers,* Vol. 58, Feb. 1936, pages 115-116. A few preliminary figures of the test still in progress with this austenitic steel are given. No appreciable loss of ductility nor impairment of physical properties was found regardless of the time or temperature of heating, or whether the specimen was stressed or not. The discrepancy of this result with that on some other material is commented on. Ha (11b)

Heat Conductivity of Pure Iron and Commercial Steels (Die Wärmeleitfähigkeit von reinem Eisen und technischen Stählen) F. BOLLENRATH & W. BUNGARDT. *Archiv für das Eisenhüttenwesen,* Vol. 9, Nov. 1935, pages 253-262. A correlated abstract of the existing data on heat conductivity for pure Fe and C and alloy steels. Good average values can be given for the heat conductivity of plain C steels at room temperature. The data on the alloy steels are fragmentary and inconsistent and show only qualitatively the effects of the different alloying elements. Values of heat conductivity of several commercial type steels are given. 38 references. SE (11b)

Tough Cast Iron, Properties and Production in the Cupola Furnace (Fonte resistante, Proprietes et Fabrication au Cubilot) GUY HENON. *Usine,* Vol. 45, Feb. 13, 1936, page 27. The composition of this remelted cast Fe is 2.8-3.2% C, 0.6-0.8% Mn, less than 0.3% P and less than 0.008% S; it has a high modulus of elasticity, takes a fine polish after machining, has high wear resistance and dense structure with absence of physical defects. The Si content must be adjusted according to the thickness of the pieces to be cast:

average thickness in mm.	average Si content in %
6-10	1.80
10-15	1.65
15-25	1.50
25-35	1.35
35-45	1.20

The charge should be made up in such manner that the material does not acquire any hereditary properties; this is realized by using 25% each of scrap of same manufacture, fine-structure cast Fe of determined composition, slugs half steel and half hematite, and ordinary hematite castings. Ha (11b)

12. EFFECT OF TEMPERATURE ON METALS AND ALLOYS

L. JORDAN, SECTION EDITOR

The abstracts in this section are prepared in co-operation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

Volatilization Velocity of Metals in a Gas Atmosphere (Die Verdampfungsgeschwindigkeit der Metalle in einer Gasatmosphäre) J. M. A. VAN LIEMPT. *Receuil Travaux Chimiques des Pays-Bas,* Vol. 55, Jan. 15, 1936, pages 1-6. For metal wire the following formula expressing the volatilization speed in a gaseous atmosphere has been derived

$$\frac{V}{V_r} = 1 - \frac{2}{\pi} \text{arc sin} \left(\frac{1}{1 + \frac{3.4}{r.d_g.d_m.p\ 10^{19}}} \right)$$

wherein V = volatilization speed in gas atmosphere, V_r same in vacuum, r = half of wire diameter in cm., d_g = diameter of gas atom in cm., d_m = diameter of metal atom in cm., p = gas pressure in cm Hg at 20° C. The formula is in satisfactory agreement with experimental results. At higher pressures, divergencies occur which are easily interpreted. EF (12)

Non-Ferrous Metals in Relation to Prolonged Stress—A Review of Recent Researches. *Metal Industry,* London, Vol. 47, Sept. 6, 1935, pages 223-227. Tronton & Rankine, Phillips & Andrade are considered as pioneers in the study of "creep" on non-ferrous alloys. The work of Andrade was the most comprehensive and resulted in important conclusions. Flow of metals was found to be (1) instantaneous deformation, (2) temporary, progressing as the cube root of time, or (3) permanent, characterized by steady increments of length per unit flowing length. This was designated as "viscous" but would now be called "creep." More recent investigators have shown the early generalization to be inadequate. Rosenhain & Ewen found 2 types of deformation, viz. movement by crystalline slip leading to transcrystalline fractures and grain boundary movement leading to intercrystalline fractures. Marked differences in behavior were shown in creep tests for rolled and cast material. Hot and cold rolling, temperature of testing, method of fabrication, period of aging, as well as the composition of the alloys studied, appeared to be governing factors in creep testing. The importance of ductility is indicated. The work of various investigators on Pb, single crystals of Pb, of Al-alloys, of age-hardening alloys and Sn-bronzes are discussed. Creep is compared with Brinell hardness tests. 35 references. HBG (12)

2 **Hall Effect in Nickel on Passing the Curie Point (Halleffekt in Nickel beim Oberschreiten des Curiepunktes)** I. K. KIKOIN. *Physikalische Zeitschrift der Sowjetunion,* Vol. 9, No. 1, 1936, pages 1-2. In German. The temperature relation of the Hall effect in Ni is investigated up to the temperature of the Curie point. Simultaneous measurement of the magnetization on the same sample yielded the "true Hall coefficient R_1" whose absolute magnitude and relation to temperature is given. Comparison with results of other investigations extending beyond the Curie point showed no marked break point at the Curie temperature. A tentative explanation is offered and tests on Ni-Cu alloys are announced. EF (12)

3 **Materials for Steam Pipes Used at High Temperatures (Werkstoffe für Dampfleitungen mit hoher Temperatur)** WILHELM PAUL. *Die Wärme,* Vol. 58, Dec. 21, 1935, pages 839-843. Strength, elongation, and creep resistance of 3 C, Mo, Mo-Cu and Cr-Mo steels at 20°-550° C. (600° C.) are tabulated. Effect of addition of 0.5% of C, Ni, Si, W, Co, Mn, Cr, Cu, Ti, V, Mo to 0.1% C steel on physical properties at 400° and 500° C. and additional costs in RM/ton are graphically shown. Creep resistance curves of 0.1% C-0.5% Mn steel with and without variously proportioned additions of Mn, Si, Cu, Mo, Cr (analyses given) are compared with the German standard structural steel St 37. EF (12)

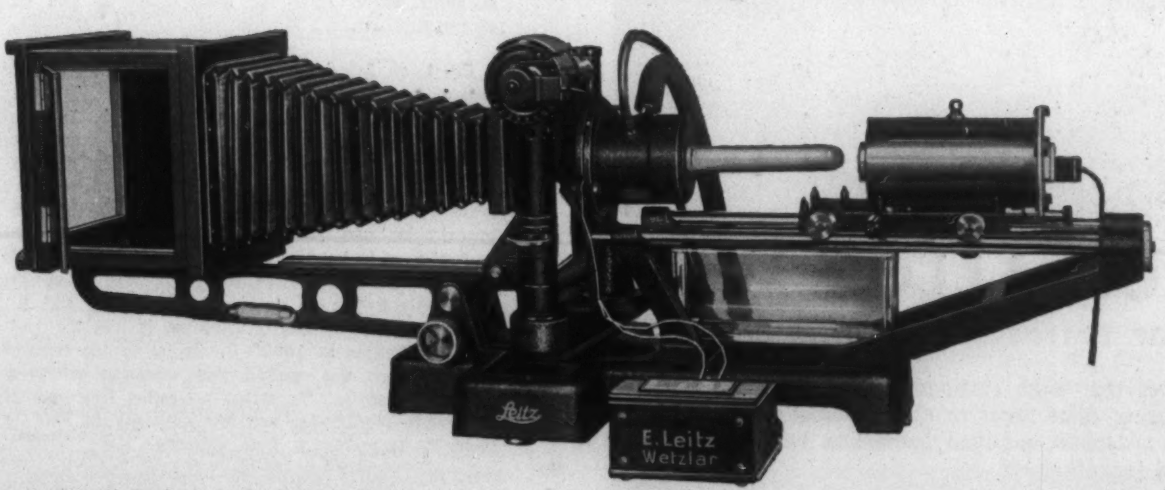
4 **Seizing of Threaded Joints at Elevated Temperatures (Das Festfressen von Schraubenverbindungen bei höheren Temperaturen)** H. VOLLBRECHT. *Archiv für das Eisenhüttenwesen,* Vol. 9, Feb. 1936, pages 397-404. The seizing of threaded joints of various C, Cr-Mo, austenitic Cr-Ni, and nitrided Cr-Al-Mo steels on heating to 500° C. was studied. As oxidation occurred the frictional values increased. In threaded joints the tendency to seizing diminished, the smaller the difference in surface hardness between the nut and bolt and the thinner the oxide layer. When the oxide layer was less than 150 μμ thick no seizing occurred. Surface pressure had no effect on seizing. SE (12)

5 **Mechanical Testing at Elevated Temperatures (Les essais mécaniques à chaud)** JEAN GALIBOURG. *Revue de Métallurgie,* Vol. 33, Mar. 1936, pages 157-163. Description of methods used at present. 21 references. JDG (12)

Determines

EXPANSION-TEMPERATURE CURVES

Automatically AND IN DETAIL



The Leitz Dilatometer does three things accurately and automatically. It takes the metal specimen through any desired temperature range. It records the expansion curve. It spots the critical points.

On the plate is recorded the history of that particular metal specimen as it changed with changing temperatures.

If you want accuracy combined with utility in making thermal analyses of metals and other determinations, you should use the Leitz Dilatometer.

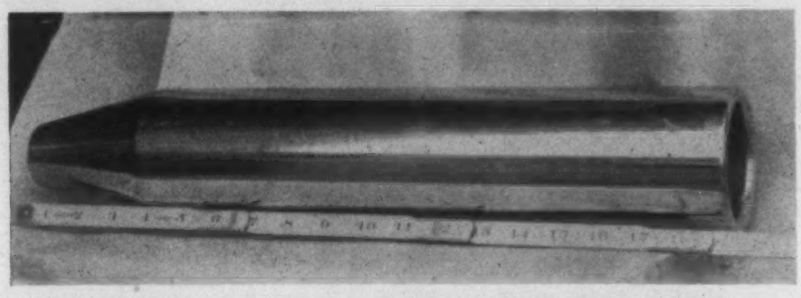
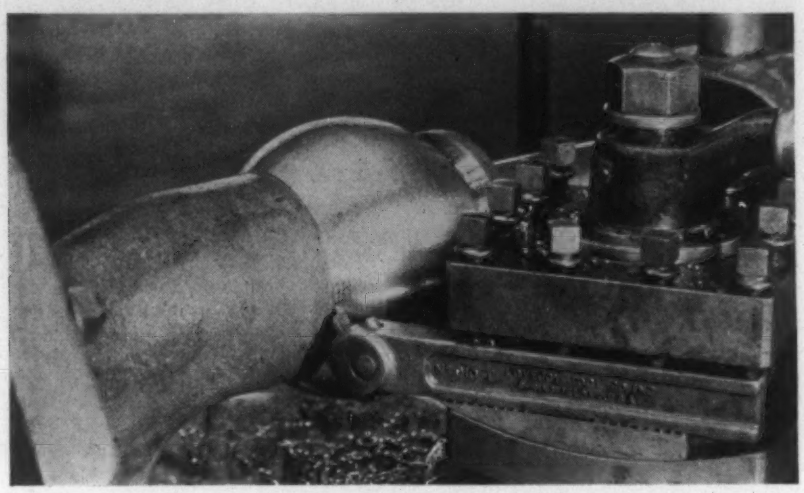
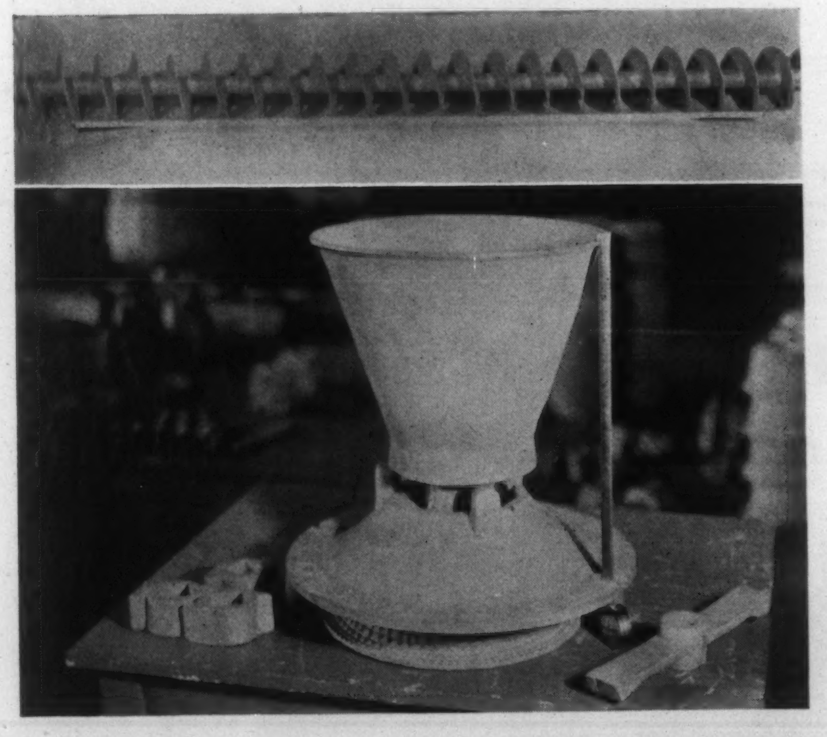
FINISHED CASTINGS





or

ROUGH CASTINGS



in DURCO ALLOY STEEL

for corrosion service

Both the finished and the rough castings shown above are made of Durco corrosion-resisting Alloy Steel to the customer's specifications. The top piece is a tapped, polished immersion burner; the next, machining a ball-and-socket joint.

The screw conveyor, and the hopper and grinder were made in the rough to be finished by the buyer.

Whichever you want, we shall be glad to have your inquiry for corrosion-resisting equipment.

13. CORROSION AND WEAR

V. V. KENDALL, SECTION EDITOR

Cylinder Wear Measured from Photomicrographs of the Lubricating Oil. N. A. Everett. *Diesel Power,* Vol. 13, July 1935, pages 454-455. Report on series of tests, at Pennsylvania State College, for observing the behavior of various lubricating oils when used in automobile engines under operating conditions. Photomicrographic examination of the used lubricating oil was found to be suitable for estimating the nature and amount of sand, C, metallic Fe and Fe oxide picked up by the oil during operation. Method is exceptionally suitable for identifying contaminating Al, babbitt, Cu, etc. particles, although present experiments are concerned chiefly with Fe. Photomicrographs are included. FPP (13)

Effective Corrosion Protection by Eloxal Films on Copper-containing Aluminum Alloys (Wirksamer Korrosionsschutz durch Eloxalschichten auf kupferhaltigen Aluminiumlegierungen) Alexander Jenny. *Aluminium,* Vol. 18, Mar. 1936, pages 97-99. In a controversy, the view expressed by R. Sterner-Reiner (*Aluminium,* Vol. 17, July 1935, pages 370-374) that Cu-containing Al alloys cannot be made more resistant against corrosion by the eloxal process is refuted by the author who shows by several examples that by a correct anodic and subsequent treatment a considerable increase in corrosion resistance, particularly against seawater, can be obtained in Cu-containing Al alloys as in all others. Ha (13)

Corrosion Tests (Ensayos de Corrosión) J. Lisbona. *Metalurgia y Construccion Mecanica,* Vol. 2, Apr. 1936, pages 7-8. Methods to determine corrosion resistance of a material, the preparation of specimens, and the evaluation of the test results are briefly described. Ha + FRM (13)

Behavior of Ordinary and of Special Steels in Galvanizing Baths (Sul comportamento degli acciai comuni e speciali nei bagni di zincatura) I. Musatti & A. LaFalce. *La Metallurgia Italiana,* Vol. 28, Jan. 1936, pages 1-17. The corrosion of various types of steel by molten Zn at temperatures of 460°-520° C. has been measured. Corrosion is little affected by addition of C up to 0.2-0.3%, but increases rapidly with higher C, becoming very strong for 0.5% or more C. Si affects corrosion more markedly, 0.2% increasing corrosion 3 times, and 0.87% Si increases corrosion 25-30 times that of Si-free steel. Mn, in amounts normally present, 0.03-0.3%, has practically no influence. Cr has very little influence, 0.56% causing an increase of about 50% in corrosion over a similar Cr-free steel. Ni (about 5%) improves the resistance so as to practically counterbalance the effect of Cr. The resistance of stainless steel and Cr-Ni steel (18-8) to corrosion is about equal to that of low C steel. S, up to 0.080%, and P, up to 0.055% do not affect corrosion appreciably. Increased temperature increases corrosion in all cases, temperatures of 480° C. or more causing a marked increase; the corrosion of 18-8 steel at 520° C. is 3 times that at 460° C. AWC (13)

Modern Theories of Corrosion. Part I. Water Line Corrosion. J. E. O. Mayne. *Journal of the Chemical Society,* Mar. 1936, pages 366-368. Although the distribution of corrosion on steel plates immersed in N/10 KCl has been investigated by Evans and others, and explained by the electro-chemical theory, no satisfactory solution has been given on water line corrosion. The author, by means of suitable laboratory experiments, suggests that water line corrosion is due to the potential existing at the surface of the solution. It was found that corrosion is depressed by the presence of C_2H_5OH in the corroding solution. Technically, corrosion is due to the negative adsorption of the solute at the surface of the solvent. AAA (13)

Excessive Ring Wear. Elton Sterrett. *Diesel Power,* Vol. 14, Apr. 1936, pages 223-225. A case of one sided ring wear, causing noisy engine operation during starting-up periods, is described. Condition was attributed to uneven, heavy C deposit which was thereafter obviated by removing 2" of metal, thus allowing oil-laden air to enter the upper space in two eddying streams instead of one concentrated jet. FPP (13)

Effect of Alloying Elements on the Oxidation of Iron (Einfluss von Legierungszusatzen auf das Zundern des Eisens) E. Scheil & K. Kiwit. *Archiv für das Eisenhüttenwesen,* Vol. 9, Feb. 1936, pages 405-416. The effect of alloying elements on oxidation of various alloy steels at 900°, 1000°, 1100° and 1200° C. was studied. During oxidation distinct oxide layers are formed. The elements more noble than Fe as well as those less noble tend to concentrate between the Fe and oxide layer. Al, Cr, and Si which decidedly raise the resistance to oxidation and Ti, Be, and V which have a smaller effect all tend to form protective oxide layers. The contents of S, B, Mo, W, P, As, and Sb were raised between the Fe and oxide layer; Mn was an exception in this. The addition of more noble metals to steel such as Cu, Ni, and Pt, did not increase the oxidation resistance. Pt indeed decreased it. In the system Fe-Cr-Ni, no alloys resistant to oxidation at 1000° C. similar to the corrosion resistant alloys were found. The conclusion was reached that oxidation entails a movement of the Fe atoms rather than of O_2. To attain protection from oxidation, the material should have a low rate of diffusion and low solubility in FeO, or else form a protective layer about Fe to prevent it from diffusing. SE (13)

Determining Solubility of Steels in Acids (Bestimmung der Säurelöslichkeit von Stählen) R. Walzel & F. Neuwirth. *Archiv für das Eisenhüttenwesen,* Vol. 9, Mar. 1936, pages 451-457. The effect of specimen form, composition of solvent, time, presence of reducing agents, saturation, etc., on the rate of solution of various steels in cold or moderately warm acids was determined. The results were not reproducible. Better reproducibility was obtained with boiling acids. No relationship was found between the natural corrodibility of steels and their rate of solution in acids. SE (13)

Taking Up Wear on Bridge Pins. *Railway Engineering & Maintenance,* Vol. 32, Apr. 1936, pages 235-236. Novel method of eliminating play in pin holes, with means of providing adjustment on both tension and compression devices is described. Method has been successfully applied on a through truss bridge over the Clinch River. FPP (13)

14. APPLICATION OF METALS AND ALLOYS

Nickel and Its Alloys in Petroleum Refining (Das Nickel und seine Legierungen in der Petroleum raffinerie) R. W. Müller. *Werkstoffe & Korrosion,* Vol. 11, Mar. 25, 1936, pages 9-13. The necessity for using high-grade materials in refining industries is explained and the use of Monel metal, Cu-Ni alloys with less than 50% Ni, Inconel (Cr-Ni alloy with about 14% Cr), Ni plated steel, alloy steel with low Ni content and cast Ni steel, and gray Fe with Ni additions (Ni-resist) is reviewed with description of the different parts and fields in operating processes where the materials are best suited. Some operating results are given, and mechanical properties of the materials considered. Ha (14)

Metallurgy in Aircraft Engine Construction. R. C. Moore. *Canadian Chemistry & Metallurgy,* Vol. 20, Mar. 1936, pages 81-82. Higher compression ratios, higher engine speeds and the use of high-grade tetraethyl gasoline have all contributed to increased h.p. The weight/h.p. ratio has been reduced to 1.33/h.p. The composition of the average radial aircraft engine today is approx. 50% steel and 50% Al and Mg alloys with a small percentage of bronze. Selection of steel for various parts and the control testing are briefly touched upon. The magnetic method of examination is one of the most valuable yet applied to aircraft engine parts. WHB (14)

G. L. CRAIG, SECTION EDITOR

Studies on Bearings with a New Type of High Pressure Lubrication (Untersuchungen an Gleitlagern mit einer neuartigen Schmierung bei sehr hohen Drucken) G. Welter & W. Brasch. *Metallwirtschaft,* Vol. 15, Mar. 6, 1936, pages 227-229. Experiments show that when bearings are lubricated under a pressure of 100-200 atmospheres the starting and running frictions are both greatly reduced, making possible the use of new Al and Zn bearing alloys which do not contain Sn. GD (14a)

Stress Calculations for Thin Aluminum Alloy Sections. S. A. Kilpatrick & O. J. Schaefer. *Product Engineering,* Vol. 7, Apr. 1936, pages 129-133. A method of calculating stresses in thin Al parts, particularly in aircrafts, is explained, taking into account the peculiarities of the material and special sections and fabricated structures used in aircraft. Ha (14a)

Use of Aluminum in the Alcohol Industry (Verwendung von Aluminium in der Spiritusindustrie) Lühder. *Aluminium,* Vol. 3, Feb. 1936, pages 62-63. Al apparatus has been used successfully in alcohol distillation where bronze had failed. Ha (14a)

Treatment of Water Supplies. Hermann Bach. *Chemical Trade Journal & Chemical Engineer,* Vol. 95, Sept. 14, 1934, page 184. See "Magnesium Metal for Treating Water," *Metals & Alloys,* Vol. 5, July 1934, page MA 369. MS (14a)

New Steel Sheet House in the Low-Cost Field. *Iron Age,* Vol. 136, Dec. 26, 1935, pages 17D-17E. Describes sheet steel house manufactured by National House, Inc. Structure is assembled from standardized parts of cold rolled Cu bearing black sheets. Outside wall panels are made of No. 14 gage black sheets of standard width of 2 and 4 ft., and 9 ft. high. Interior of walls are steel, sprayed with 2 coats of rust proof paint. They are made with 4, 5 or 6 rooms, and range in price from $3,000 to $6,000. VSP (14a)

Deformation, Heat Treatment, Solubility (Verformung, Wärmebehandlung, Löslichkeit) First Report of the Committee of Non-ferrous Metals. *Korrosion & Metallschutz,* Vol. 12, Jan.-Feb. 1936, pages 2-28. The very exhaustive investigation deals with non-ferrous metals only. Their solubility is determined by their constitution and the manner of pretreatment. The solubility of cold-worked, monophasic Cu-Zn and Cu-Ni alloys follows the solubility law of Heyn. Various kinds of heat treatment and degrees of deformation had no effect on the solubility. The non-ferrous metals do not show any pronounced change of solubility in the whole range of cold working (up to close to ultimate strength). Electric conductivity and electrochemical potential of solution can be used to judge the solubility of monophasic Cu-Zn alloys. Tables show the test results and comparative results with Fe and steel, curves, micrographs are given. 118 references. Ha (14a)

Aluminum in the Shop Equipment Industries. *Machinery,* N. Y., Vol. 42, Feb. 1936, pages 389-391. Present uses of Al in machine tools (housings, supports, portable tools), in paints and possible further extension of the uses are reviewed. Ha (14a)

Bronzes for Chemical Plant. *Chemical Trade Journal & Chemical Engineer,* Vol. 95, Oct. 12, 1934, page 262. From *Nickel Bulletin.* Addition of 0.5-2% Ni to bronzes improves mechanical properties, refines grain, increases soundness of castings, and prevents segregation of Pb in Pb bronzes. Examples of its use in castings are heat exchangers, tube plates for condensers for chemical work, and pressure vessels. MS (14a)

Nickel Plated Steel Sheets in the Manufacture of Soap (Nickelplattierte Stahlbleche für die Seifenherstellung) *Nickel Berichte,* Vol. 6, Mar. 1936, pages 37-39. Fe boilers used in soap industry exhibited severe corrosion defects at the interface air/liquid and their life could be materially extended by employing Ni-clad steel for the upper half of the boiler. The ratio of the corrosion resistance in 30-50% NaOH at 82° C. of Ni: Monel metal: steel: cast Fe = 400 : 200 : 11 : 5.5. Besides boilers and tubes structural members of the roof have been made of Ni-plated steel. It is stated that the corrosion products of Fe lead to discoloration and impair the odor of soap. The utilization of Monel metal, Ni and Ni-plated steel for various members of equipment used in soap manufacture is discussed. EF (14a)

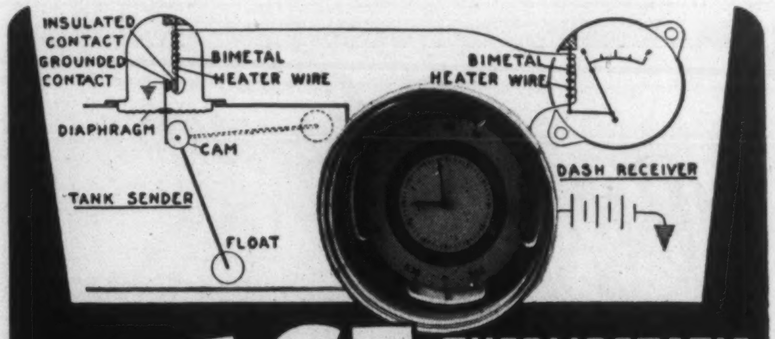
Non-ferrous Alloys Available for the Use of Industry. *Aluminium & Non-Ferrous Review,* Vol. 1, Jan. 1936, pages 135-138; Feb. 1936, pages 198-201; Mar. 1936, pages 241-242. Details of characteristics and uses of proprietary Al alloys produced by Northern Aluminium Co., British and Dominions Ferraloy Ltd., Aluminium Union Ltd., and Birmingham Aluminium Casting Co. Ltd. and of the Manganese Bronze and Brass Co.'s high tensile bronzes and brasses. JCC (14a)

Aluminum for Conduits for Beverages (Aluminium für Getränkeleitungen) *Aluminium,* Vol. 18, Feb. 1936, page 54. The German Labor Department has permitted Al pipes and conduits in addition to Sn and glass for all kinds of beverages, especially for beer. Ha (14a)

New Industrial Uses for Silver. Lawrence Addicks. *Mining & Metallurgical Society of America Bulletin* No. 236, Vol. 29, Jan. 1936, pages 5-21. Use of Ag for bactericidal purposes is discussed at length. Ag as a corrosion-resisting metal, Ag in alloys, and Ag commutators are described briefly. AHE (14a)

Bearing Metals for Internal Combustion Engines. II. H. N. Bassett. *Gas & Oil Power,* Vol. 30, Jan. 1935, pages 20-21. Impurities exert a powerful effect on the structure and physical properties of bearing metal alloys for internal combustion engines. Pb, the most common impurity, decreases ductility, increases susceptibility to high temperature fracture under load, and in certain combinations with Cu and Sb, may develop "wiping" of the Pb-Sn eutectic at high rubbing speeds and high shock loads between 250° and 400° F. Ni, an unusual impurity, reduces the hardness and lowers resistance to crushing. Zn at low temperatures is without effect but raises the yield point considerably at 100° C. Al is very dangerous because of the pronounced liquation induced by its presence, and the replacement of cubic crystals with undesirable globular structure. Bi lowers compressive flow-point at temperatures above atmospheric. Bronzes also are used for internal combustion engine bearings, a wide variety of compositions being available. Methods of casting are described, and the entirely beneficial effect of P, both as deoxidizer and alloying element, is discussed. FPP (14a)

Magnesium in Aeronautic Constructions (Le Magnésium dans les Constructions aéronautiques) R. de Fleury. *Usine,* Vol. 45, Feb. 27, 1936, page 29; Mar. 5, 1936, pages 34-35. Under this title, a comprehensive review of properties, manufacture and use of Al-Cu-Mg, Mg-Cu-Si, Mg-Mn alloys, of methods of studying complex alloys, melting practices, kind of molding sands used for castings, forgings of Mg and fatigue resistance is made. The fatigue resistance of pure Mg is given as 7 kg./mm.², for alloys with 3-15% Al 11-12 kg./mm.², alloys with 3% Cu and 3-12% Al 10-13 kg./mm.² Applications, especially in landing gears, are described. Ha (14a)



CHACE THERMOSTATIC BIMETAL
used in KS TELEGAGE

TO INDICATE AMOUNT OF GAS IN AUTO TANK

Above diagram indicates empty gasoline tank. As tank is filled, float raises and cam action forces contact against "Sender" bimetal. This pressure causes electric current to generate heat, bending Chace Thermostatic Bimetal element. Current carried through to "Receiver" bimetal element, bends it and causes indicating needle to record gasoline level on dash of auto. Many of the automatic controls to be found on today's automobiles employ Chace Theromostatic Bimetal as the dependable active element.

Experiences on High Pressure Boiler Plates (Erfahrungen mit Hochdruckdampfanlagen) Otto Schöne. *Die Wärme,* Vol. 58, Nov. 23, 1935, pages 765-774. Part of the paper is devoted to experiences on the use of high temperature service steels above 400° C. and on the weldability of these steels. Diagrams show the hardness distribution around a weld of a Cr-Ni-Mo steel joined by 2 different welding methods.
EF (14b)

Wire Ropes and Pulley Stress. Richard Saxton. *Mechanical Handling,* Vol. 23, Feb. 1936, pages 35-36. Excessive wear of strand ropes can usually be traced to unsuitable grooves in the pulley face, leading to crushing, or the choice of too small a pulley diameter. The section of rope making contact with the pulley when the load is first applied is particularly susceptible to damage by overloading, and should be cut out at frequent intervals. Recommended pulley diameters for various sizes of ropes are tabulated.
JCC (14b)

Better Bridges Require Less Maintenance. C. E. Webb. *Railway Engineering & Maintenance,* Vol. 32, Jan. 1936, pages 27-28. The advances in steel bridge practices resulting from better materials, improved methods and modern equipment are reviewed. Refinements in detailing have resulted in longer life and lower maintenance costs. Welding has as yet made small progress in the construction of new R.R. bridges but is proving useful in the repair and strengthening of old structures. Experience shows that bridge replacements are required usually because of inadequate details rather than of overstress in the main members.
FPP (14b)

Stainless Steel Rope for Rigging. R. L. Hopkins. *Marine News,* Vol. 22, Jan. 1936, pages 20-21. Stainless steel does not affect compass readings, being non-magnetic. Other advantages cited; construction of rope strands discussed; reduced diameter due to use of higher strength steel results in less wind resistance.

Seamless Tubes for Steam (Les Tubes sans Soudure pour Tuyauteries de Vapeur) Laurent. *Science et Industrie, Métaux et Machines,* Vol. 19, Dec. 1935, pages 444-446. Deals with selection of steel and process of tube manufacture (Mannesmann and Stiefel processes). Sizes of tubes are also discussed.
FR (14b)

A Review of Structural Steelwork Developments. C. J. Kavanagh. *Iron & Coal Trades Review,* Vol. 132, Jan. 17, 1936, pages 127-128. The growing importance of welding and high-tensile steels in constructional work is discussed; some recent British applications are briefly described.
Ha (14b)

Consumer Goods—An Expanding Market for Iron and Steel. Neil E. MacMillan. *Iron Age,* Vol. 137, Jan. 2, 1936, pages 78-79. Considers such domestic equipment as electric refrigerators, washing machines, stoves, radios, vacuum cleaners, toys and play ground equipment, oil burners and stokers and radiators.
VSP (14b)

Stainless-Steel Venturi-Flume Meters. *Engineering,* Vol. 141, Mar. 6, 1936, pages 259-260. Believed to be the first time that non-corrodible steel has been used for facing the whole surface of a venturi-flume meter. Steel used was "staybrite" in descaled condition. Apart from durability due to immunity from corrosion, the steel lining will preserve the original contour of metering throat.
VSP (14b)

Bonded Metals. *Engineer,* Vol. 161, Feb. 28, 1936, page 230. A brief notice about a process developed by Spear and Jackson, Limited, of Sheffield by which any 2 metals with melting points above 1200° C. can be bonded together. After bonding the 2 metals can be worked and heat treated together. No particulars are given of the bonding process. It can be used for facing cutters with high-speed steel or for plating mild steel with a thin layer of stainless steel.
LFM (14b)

Nickel-Clad Steel. *Nickel Bulletin,* Vol. 9, Feb. 1936, pages 25-28. Ni is hot-rolled onto the steel slabs, procedure is briefly described. The material is used for tanks, containers of caustic alkalies, water storage, e.g. hot water storage in laundries, and for the sulphonating equipment in the leather industry.
Ha (14b)

Steels Used for Die-casting Dies. *Machinery,* N. Y., Vol. 42, Feb. 1936, pages 369-371. The particular requirements of steels for this purpose are machineability, stability in heat treatment, resistance to heat checking and to deformation, to cleavage cracking on sudden heating or cooling (toughness), to the erosive actions of molten metal, cleanliness and uniformity. A list of 8 types of alloy steels is given with their chemical composition, and the Brinell hardness which they must possess for use as materials for die-casting of Sn, Pb, Zn, Mg, Al and Cu.
Ha (14b)

Special Steels in American Bridges. *Engineer,* Vol. 161, Mar. 6, 1936, page 255. In recent years there has been a decided trend toward a higher Mn and lower Si content. Ni steel with about 3.25% Ni has been used in a number of bridges. In the Golden Gate bridge there appears a decrease in C from 0.345-0.27%; a decrease in Si from 0.27-0.25%, and an increase in Mn from 0.77-1.25%. Series of studies of alloy steels for bridges with Cu, Cr, Mn, Ni, Mo, Si and V, may result in changes in design.
VSP (14b)

The Selection of Mould Steel. J. C. Alexander. *Machinery,* London, Vol. 47, Jan. 16, 1936, pages 469-470. Brief, general discussion of high C-high Cr, low W and Cr, Mn-Cr, Ni-Cr, C-tool, stainless and mild and soft iron for molds. Characteristics desired are easy machineability, freedom from distortion during thermal treatment, low hardening temperature, intense surface hardness and internal toughness, capacity to take and retain mirror polish, abrasion resistance, nonadherence to molded product, capacity to respond to rapid thermal treatment and stainlessness.
WB (14b)

Stainless Steel in Locomotive Engineering. *Railway Gazette,* Vol. 64, Mar. 20, 1936, pages 567-568. Two types of stainless steels used in R.R. locomotive and car construction are classified as (1) martensitic, 13% Cr and .30% C and (2) austenitic, usually 18 Cr, 8 Ni. Martensitic stainless steels are used for valves or seatings of boiler fittings and other parts subjected to erosion. Precautions against seizing, galvanic corrosion and loss of ductility are cited. Austenitic steel is used largely in passenger cars for ornamental purposes, in kitchen and lavatory fixtures, and in a few notable cases for the entire body of articulated trains. Machining aids are listed.
FPP (14b)

Novel Concrete Pumps (Neuartige Betonpumpen) *Nickel Berichte,* Vol. 6, Apr. 1936, pages 59-60. Stresses the difficulties encountered in the recent design of concrete pumps. Centrifugally cast Fe alloyed with Ni, Cr and Mo and hardened to 500 Brinell was employed to combat wear of the cylinders. The pistons consisted of cast Fe with 3.2% C, 1.75% Si, 0.7% Mn and 2.5% Ni. The hardness is 350 Brinell. A drawing shows the various materials utilized in the construction of the concrete pump.
EF (14b)

Automatic Valves (Selbstgesteuerte Ventile) *Nickel Berichte,* Vol. 6, Feb. 1936, pages 23-24. The main feature of this valve is that it is operated by the expansion of 2 steel rods (27% Ni, 5% Mo) inside a Ni-Cr heater coil. EF (14b)

Steels for Marine Purposes. *Journal of Commerce, Shipbuilding & Engineering Edition,* Jan. 9, 1936, pages 1, 3. A review of recent steel developments of interest to the marine industry deals with the corrosion resisting steels containing Cu and Mo; the stainless, heat-resisting steels containing 25% Cr, 20% Ni; the nitriding of stainless steels; the centrifugal casting of stainless steel; the use of Ni-Cr-Mn steels for pressure vessels; Ni wrought Fe; and a low C, Ni-Mn steel of great mechanical strength and high elastic limit. Consideration is also given to steel treatments and processes including hard-facing processes, metallizing, and bright annealing.

RICHARD RIMBACH, SECTION EDITOR

Current Activities of the Metallurgical Division of the U. S. Bureau of Mines. R. S. DEAN. *Mining Congress Journal*, Vol. 22, Apr. 1936, pages 20, 37. The following are among the problems studied at present at the U. S. Bureau of Mines: Production of carbon-free ferro chrome; electrolytic production of Mn; explosive shattering of minerals, at pressures up to 4000 lbs.; the use of flotation and high-frequency jigs in the treatment of Au and Ag ores; treatment of high grade Pb concentrates to convert the galena into metallic Pb; recovery of S from smelter gases; the effect of the CaO-MgO ratio in blast furnace slags in the desulphurization of the Fe. BHS (15)

Present State of the Electro Metallurgical Industries, with Particular Attention to Norwegian Conditions (En Oversigt Elektrometallurgiens Nuvaerende Stilling, Med Spesielt Henblikk paa Norske Forhold) ANTON GRÖNNINGSAETER. *Teknisk Ukeblad*, Vol. 83, Mar. 5, 1936, pages 108-114. Address before Norwegian Engineering Societies on Feb. 21, 1936. Discusses the various electrometallurgical processes, from the refining of precious metals to the electric production of Fe, steel, and ferro alloys. Of particular interest to Norway are the electrolytic refining of Ni, with about 10% of the world production refined at Kristiansand, and the electrolytic Zn process, the Eitrheim plant having an annual output of 45,000 metric tons of this metal. Al is produced in Norway at a rate of about 30,000 tons annually. Important industries are also the production of ferro alloys, particularly ferro silicon and ferro manganese. Elastic pig iron is made at two plants. The Norwegian Hole furnace has lately been introduced in Italy, where 5 furnaces are now in operation, and an installation will soon be completed at Domnarivet, Sweden. Production of alloy steel in induction furnaces is also making good progress. The development of the Soderberg electrode, possibly the most important achievement in electric smelting during the last decade, has made possible the construction of the large carbide and ferro alloy furnaces now in use, and it has also led to very important improvements in the Al industry. BHS (15)

Electrical Developments in the Steel Industry. H. A. WINNE. *Blast Furnace & Steel Plant*, Vol. 24, Jan. 1936, pages 71-73, 90. Condensed as **Electric Furnace Developments** in *Heat Treating & Forging*, Vol. 22, Jan. 1936, pages 44-45. Developments and installations by General Electric Co. of rolling-mill drives; ventilation and cooling of mill motor room; gear motors as drag generators; d.c. contactors; factory-assembled control structure; bright-annealing, heat treating, and brazing furnaces; atmosphere control equipment; Calrod heating elements; electric welding equipment; and resistance welder control. MS (15)

Distribution of Useful Metals in the Earth's Crust (Die Verteilung der nutzbaren Metalle in der Erdrinde) I. NODDACK & W. NODDACK. *Angewandte Chemie*, Vol. 49, Jan. 4, 1936, pages 1-5. The geochemical conditions of the earth are explained and a table for the frequency of a metal as percentage of the total of all elements is given for the whole periodic system. O and Si are the most abundant. An estimate of the total available supply of metals in the different countries is made for Fe, Ni, Mn, Cr, Cu, Zn, Pb and Sn and figures are given for the amount of these metals in the earth's crust of 1 km. thickness. The most important processes for the working of metals (preparation, reduction, flotation, magnetic separation, etc.) are discussed briefly. Ha (15)

Research as Related to the Iron and Steel Industry. W. H. HATFIELD. *Proceedings Staffordshire Iron & Steel Institute*, Vol. 50, Session 1934-35, pages 69-73. A brief account of the research which is at the present time being carried on in England. A complete coöperation exists between the National Federation of Iron and Steel manufacturers through its Research Council and the National Physical Laboratory and Iron & Steel Institute. A considerable amount of work on coal and coke has been done by the National Coke Research Committee. These are committees on blast furnace, the open-hearth, rolling mill practice, on the heterogeneity of steel ingots, and on corrosion. GTM (15)

Corrigan, McKinney Steel Company (Subsidiary of the Republic Steel Corporation) CHARLES LONGENECKER. *Blast Furnace & Steel Plant*, Vol. 24, Jan. 1936, pages 75-81. Outlines history of company and describes plant at Cleveland, O. Comprises 204 coke-ovens; 4 blast-furnaces; 14 open-hearth furnaces ranging from 113 to 200 tons in capacity; a 40″ and a 32″ 2-high reversing blooming-mill; a 6-stand 21″ and a 6-stand 18″ billet mill; a 4-stand, 2-high 22½″ and a 7-stand, 2-high, 18″ sheet-bar mill; a 10″ merchant mill consisting of 4-14″ roughing stands, 4-12″ stands, 3-10″ intermediate stands, and 4 finishing stands; and a 12″ merchant mill consisting of 14 stands. MS (15)

Position of Kaiser-Wilhelm-Institute for Metal Research with Regard to Science and Economics (Die Stellung des Kaiser-Wilhelm-Instituts für Metallforschung zu Wissenschaft und Wirtschaft) W. KÖSTER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 80, Jan. 4, 1936, pages 45-46. Aim and scope of work of Institute are outlined; it is to be "the scientific conscience of the metal technique and endeavors to be the conscientious adviser and guide in technical-scientific problems." Ha (15)

Glances at Industrial Research. E. R. WEIDLEIN & W. A. HAMOR. Reinhold Publishing Corporation, New York, 1936. Cloth, 5 x 7½ inches, 246 pages. Price $2.75.

Partly a discussion of the history of Mellon Institute and of its method of operation, partly of industrial chemical research in general. An interesting chapter is that on the development of Plaskon and of the modern Toledo scale in which it is used. Some of the chapters have been previously published as separate articles, and are not very closely related, though they all refer to one phase or another of industrial research. Due to collaboration with various writers, the style varies from quite matter of fact to quite flowery. Research directors will be specially interested in Part 4, questions in industrial research management. Executives will find most of it of interest. Among the familiar names of products developed at or worked on at Mellon Institute are Redmanol, Vinylite, Prestone, Simmons beds and Visking casings for hot dogs. The emphasis is on organic chemistry, little of direct metallurgical interest is mentioned, but the metallurgist can well read it for the analogies to his own field. H. W. Gillett (15) -B-

15a. Economic

Available Raw Materials for a Pacific Coast Iron Industry. Report by E. T. HODGE to U. S. Army Engineers. 4 mimeographed volumes. Division Engineer, North-Pacific Division, (523 Pittock Block, Portland), Oregon, 1935. Paper, 8 x 10½ inches, Vol. 1—130 pages, Vol. 2—101 pages, Vol. 3 and 4, appendixes. Price $1.25 per volume, $5.00 per set.

The contents of the various volumes are: Volume I—Summary, Main Report, Economic Setting; Volume II—Market, Scrap, Economic Factors; Volume III—Iron Ore Deposits of the Western States, North Pacific Coast Iron Ore Deposits (Alaska, Yukon and British Columbia), Iron Ores of Mexico, Iron Ores of the Central Americas, Iron Ores of South America, Trans-Pacific Iron Ores; Volume IV—Fuels and Reducing Agents, Fluxes and Refractories, Manganese, Cost of Pig Iron.

This report is aimed at finding something to do with the Bonneville electric power, planned to be available in 1937. The price for power has not been determined, but it is intimated that it will run between $6.60 and $15.00 per H.P.yr. Since the Bonneville power, available near the harbor of Portland, Oregon, is a case of tide water power, analagous to Norwegian conditions, electric smelting of Fe ore is considered a possibility. It is figured that such a plant would have a potential market for 1,000 tons of pig Fe per day. On that scale it is figured that raw materials alone, choosing those most favorably situated as to location and suitability for electric smelting, would cost some $11.67. At 0.4 H.P.yr./ton, the power cost would run between $2.62 and $6.00. No figures are given for taxes, labor, upkeep, interest, and amortization, nor is comment made on what type of electric furnace would be chosen. Available ores and other raw materials are discussed in minute detail. No estimate is given of the investment required in the smelting plant and in the auxiliary fabricating plants that would have to be built before the potential market would become actual. Nor is anything said of the plans for establishing an "authority" for this district to tell its inhabitants when they may wipe their noses.

The report seems to be planned in the hope of attracting capital to make such investment, but many of the factors that would have to be considered are not dealt with at all. It is a geologist's report rather than that of a metallurgist or a business man. It seems to be very complete on the geological factors, though obviously written by a person who is too much interested in Portland to be likely to take a gloomy view of the possibilities. The Portland climate is highly recommended. H. W. Gillett (15a) -B-

Early Ordering a Safeguard of Quality in Steel Castings. R. L. COLLIER. *Steel*, Vol. 98, Mar. 23, 1936, pages 27-28. Hand-to-mouth buying of steel castings often results in a substandard product. Time is essential in making good castings. Users of castings should anticipate as far as they can their requirements in advance of actual need. This will permit assurance that new designs will be as simple as possible; the proper patterns will be made; the steel to be used will be the best suited to the application; and the castings will be the best which advance precautions and good foundry technique can supply. MS (15a)

A Cost Estimate for Aluminum from Alunite. L. C. PAN. *Chemical Industry, China*, Vol. 10, July 1935, pages 1-12. In Chinese. Based on a process of making Al from alunite through alum and calcining it to alumina, the cost of production is estimated at $0.17/lb. and the cost of plant and equipment at $1,700,000. K_2SO_4 will be a by-product. LCP (15a)

Iron and Steel in the British Empire. THOS. T. RUSH. *Iron & Coal Trades Review*, Vol. 132, Jan. 17, 1936, page 125. A detailed report on output and exports of the various countries of the empire and effects of political agreements. Ha (15a)

A Review of Iron-Ore Mining. H. K. SCOTT. *Iron & Coal Trades Review*, Vol. 132, Jan. 17, 1936, pages 122-124, 126. A survey of world deposits is made and methods of working in different countries reviewed. Ha (15a)

Outlook in the Iron and Steel Industry (Aspectos de Siderurgia) C. TAMA. *Metalurgia y Construccion Mecanica*, Vol. 2, Mar. 1936, pages 7-10. The world situation of iron and steel production, progress made in quality, metallurgical questions and recent ore reduction processes are reviewed. Ha (15a)

Continuous Sheet Mills—What They Mean to Costs and Competition. T. H. GERKEN. *Iron Age*, Vol. 137, Jan. 2, 1936, pages 82-85, 88-89. The construction of a number of continuous sheet mills during the past year, will increase total sheet and tin mill black plate in excess of 16,000,000 tons, within the next 6 months. To utilize this capacity and cost of new plants recovered, new markets must be found. Author explains how this may be done. VSP (15a)

Automobile Industry Accounted for One-Quarter of Finished Steel Consumed in 1935. T. H. GERKEN. *Iron Age*, Vol. 137, Jan. 2, 1936, opp. page 52. A chart showing the distribution to the various industries of rolled steel in 1935 according to shipments of companies producing 78.5% of the year's output. Also gives distribution and production of finished steel, 1922-1935. VSP (15a)

Mineral Production of India, 1934. *Iron & Coal Trades Review*, Vol. 132, Jan. 31, 1936, pages 231-232. The report of the Geological Survey of India gives statistics on pig iron production and exports, production, import and exports of Mn, W, Sn, Zn, Ni and chromite. Ha (15a)

Manganese Ore Production in Hunan. *Iron & Coal Trades Review*, Vol. 132, Jan. 24, 1936, page 195. History and development of mining and production in this Chinese province are briefly reviewed; about 80% of the total production of China originates in Hunan. The ore contains from 45 to 55% Mn. Ha (15a)

Centralising the Steel Trade. *Engineer*, Vol. 160, Oct. 11, 1935, page 379. Editorial discussing the problems encountered at a meeting between the British Iron and Steel Federation and the Continental Steel Cartel. Details of the export agreement such as quotas for overseas markets were discussed but no important decisions were reached. The dangers of centralized control of the industry are pointed out. LFM (15a)

Materials for the Electrical Industry. *Electrical Review*, Vol. 118, Jan. 10, 1936, page 61. Review by Metal Information Bureau, Ltd., of 1935 market conditions relative to Cu, Pb, Sn, Zn, Al, and rubber. Includes outlook for 1936. MS (15a)

British Steel Trade Makes Substantial Upward Progress. J. A. Horton. *Steel*, Vol. 98, Jan. 6, 1936, pages 278-279, 285. Reviews conditions in the iron and steel industry during 1935. Gives statistics on average monthly production, imports, and exports for 1913, 1932-Oct. 1935. MS (15a)

Lack of Confidence Still Hampers French Trade. Leon Jaudoin. *Steel*, Vol. 98, Jan. 6, 1936, pages 280-281. Review of conditions in the iron and steel industry during 1935. Gives statistics on average monthly production, imports, and exports for 1913, 1932-Oct. 1935. MS (15a)

Signs of Partial Economic Recovery Appearing in Europe. Vincent Delport. *Steel*, Vol. 98, Jan. 6, 1936, pages 276-277. Brief review of European steel industry in 1935. MS (15a)

Iron Ore Industry in 1935—Advance Summary. H. W. Davis. *United States Bureau of Mines, Mineral Market Reports* No. M. M. S. 436, Jan. 10, 1936, 3 pages. Statistical. AHE (15a)

Germany's Foreign Trade in Iron and Steel in 1935. *Iron & Coal Trades Review*, Vol. 132, Mar. 13, 1936, pages 498-499. Statistics of import and export in the various groups of products are given; an analysis is made and its relations to the British iron industry discussed briefly. Ha (15a)

French Imports and Exports of Iron and Steel in 1935. *Iron & Coal Trades Review*, Vol. 132, Mar. 20, 1936, page 537. Statistics for the different products are given; the reduction in foreign trade is commented on. Ha (15a)

Statistical Compilations on Lead, Copper, Zinc and Tin. *Metallgesellschaft*, No. 11, Feb. 1936, pages 25-30. Statistics on world production and prices from 1928 up to Jan. 1936 inclusive are compiled for these metals. Ha (15a)

Material and Power Economy in Steel Making (Die Stahlerzeugungsverfahren im Lichte der Stoff- und Energiewirtschaft) H. Bansen. *Stahl und Eisen*, Vol. 55, Nov. 14, 1935, pages 1205-1214. Discussion of the economics of the various charges in the blast furnace, bessemer, and open-hearth, and of the energy consumption. SE (15a)

Aluminum as Domestic and Exchange Material, the Recent Development of Its Uses (Aluminium als Heimstoff und Austauschwerkstoff, die neuere Entwicklung seiner Verwendung) Hans Schmitt *Aluminium*, Vol. 18, Jan. 1936, pages 21-28. The importance, from the German national economy point of view, of the widest application of Al in replacing other metals is discussed and a great number of applications in household and industry, methods of manufacturing, protecting, and electroplating are described. Ha (15a)

Steel Activity on Upgrade After Strong Recovery Year. A. J. Hain. *Steel*, Vol. 98, Jan. 6, 1936, pages 255-257. Review of American iron and steel markets in 1935. MS (15a)

Autos Gain as Leading Steel Consumer; Buildings Second. *Steel*, Vol. 98, Jan. 6, 1936, pages 206-208. Tabulates annual consumption ratios of main groups in the United States for 1922-1935 and distribution of various finished steel products in % and in gross tons to consuming groups for 1935. MS (15a)

Emphasis Is Shifting in Race for Alloy Steel Markets. *Steel*, Vol. 98, Jan. 6, 1936, page 209. Tabulates % of distribution of individual alloy steel products to consuming groups in 1935 and annual % of consumption by groups and by products for 1929-1935. MS (15a)

Canadian Output Best Since 1930. *Steel*, Vol. 98, Jan. 6, 1936, pages 317-318. Brief review of iron and steel industry for 1935. Tabulates statistics on production for 1923-1935. MS (15a)

Belgium and Luxemburg Seek to Keep Export Markets. *Steel*, Vol. 98, Jan. 6, 1936, pages 284-285. Review of conditions in the iron and steel industry during 1935. Tabulates statistics on average monthly production, imports, and exports for 1913, 1932-Oct. 1935. MS (15a)

Strong Recovery Features German Steel Industry. *Steel*, Vol. 98, Jan. 6, 1936, pages 282-283. Review of iron and steel industry during 1935. Tabulates statistics on average monthly production, imports, and exports for 1913, 1932-Oct. 1935. MS (15a)

Prosperity Returning to Lake Superior Ore Industry. *Steel*, Vol. 98, Jan. 6, 1936, pages 248-249. Review of industry in 1935. Mines shipped 28,362,368 tons by vessel. Consumption was about 30,500,000 tons. Stocks on hand at lower lake ports and furnaces Jan. 1, 1936, totaled about 31,000,000 tons. MS (15a)

Directory of Trade Names of Alloy and Special Analysis Irons and Steels. *Steel*, Vol. 98, Jan. 6, 1936, pages 41-48. Consists of 2 parts. First is an alphabetical list of American firms, with the trade-names of their products classed under each company according to types of steels. Part 2 is an alphabetical list of the significant words or symbols in trade-names. MS (15a)

Economic Crisis and Production of Common Metals (La crise économique et la production des métaux usuels) Gaston Camus. *Génie Civil*, Vol. 107, Sept. 7, 1935, pages 225-227. A survey of business statistics shows that a world-wide industrial crisis must affect the production of any country, regardless of the natural advantages it might have over its competitors. JDG (15a)

Merchandising and Selling Gray Iron Castings, 1935, Policy Holders Service Bureau, Group Insurance Division, Metropolitan Life Insurance Company, New York City, 1935, 35 pages, mimeographed. This discussion of the way gray iron foundries seek and try to hold business, is interesting and helpful. Other similar reports, available from the Metropolitan Company deal with apprenticeship in foundries, foundry health hazards, obsolete and inactive patterns, and pattern storage. HWG (15a)

Seventeenth Annual Meeting of the American Zinc Institute. *Journal of American Zinc Institute*, Vol. 16, 1935, 113 pages. Contains the reports and addresses presented at the 17th Annual Meeting of the Institute, Apr. 22-23, 1935. Among the important papers are the following: "The European and World Zinc Situation in 1934," by Oliver W. Roskill; "National Resources Board and Its Relation to the Zinc Industry," by C. K. Leith; "Cooperation Between Mining and Smelting Divisions," by C. S. J. Trench; "Economic Developments in the Zinc Industry," containing reports on the Rocky Mountain Region, the Mississippi Valley Region, and the Eastern Region. Several papers were also presented dealing with the Institute's galvanizing program and the work done to spread the use of galvanized sheets with 2 oz. coating. BHS (15a)

Mineral and Chemical Industries and Agriculture in Sardinia (L'Industrie minéral, l'industrie chimique et l'agriculture en Sardaigne) Ch. Berthelot. *Génie Civil*, Vol. 107, July 20, 1935, pages 53-57. See *Metals & Alloys*, Vol. 7, Feb. 1936, page MA 88L/10. JDG (15a)

The Advance in the Price of Gold and Its Significance to Canada. G. C. Bateman. *Transactions, Canadian Institute of Mining & Metallurgy*, 1935 (in *Canadian Mining & Metallurgical Bulletin* No. 284, Dec.) pages 552-556. AHE (15a)

20th Annual Review of the Silver Market. Handy & Harman, New York, 1935. 55 pages.

Arts and industries in the U. S. and Canada absorbed 23½ million ounces in 1935, 1½ million less than in 1934. The decrease was chiefly in sterling silverware. World production was 206½ million ounces. The history of the 1935 bull market in silver and the pressure of the silver bloc, the effect on China, and the silver panic of December precipitated by the change in attitude of the U. S. Treasury are discussed. It is concluded that none of the purposes the Silver Purchase Act was supposed to accomplish have been attained, outside the subsidy to domestic producers. This class legislation did damage in terms of foreign financial dislocation and loss of good will. The pamphlet closes with the hope that the legislators in Washington will allow the Treasury to administer the silver act in the "public interest" instead of the "silver interests." HWG (15a)

United States Leads in Striking Gain in World Output; Regains Primacy in Per Capita Use. Vincent Delport. *Steel*, Vol. 98, Jan. 6, 1936, page 210-211. Tabulates production of pig-Fe and steel ingots and castings in the different countries of the world, 1913, 1927-1935; exports and imports of the principal countries, 1913, 1932-1935; and per capita production of pig-Fe and steel ingots and castings in the United States, 1880, 1890, 1900, 1910-1935. MS (15a)

Replacement of Base Metals by Glass (Glas als Ersatz für unedle Metalle) *Keramische Rundschau*, Vol. 43, Jan. 10, 1935, pages 17-18. Announces a decree of the German Minister of Economics forbidding the use, for certain listed applications, of Cu, Ni, Sn and their alloys. Recommends substitution of glass or glass-lined units for many cases, especially large chemical equipment and household fixtures. Plated metal products are largely excluded from the decree, as are parts for motor vehicle, aircraft or marine use. FPP (15a)

World Production and World Consumption of the Most Important Metals in 1934 (Weltgewinnung und -verbrauch der wichtigsten Metalle im Jahre 1934) *Glückauf*, Vol. 72, Jan. 11, 1936, pages 42-46. The metal situation in the different industrial countries is discussed and exhaustive tables are given for production and consumption in each country of Pb, Cu, Zn, Sn, Al, Au and Ag; the available deposits are reviewed. Ha (15a)

Forecasting the Growth of the Steel Industry. Elmer C. Bratt. *Iron Age*, Vol. 137, Mar. 19, 1936, pages 48-52. A forecast of the magnitude of the steel industry in 1940. States that building of factories when current demand is sufficiently high to warrant such move is quite reasonable, whereas building according to indication of average growth is visionary and speculative. To forecast adequately some reasonable expectation must be established as to what the continuance of past growth would produce in the future. Includes statistics, equations and graphs. VSP (15a)

Value of Mineral Products of the United States, 1933-1934, by States—Summary. M. B. Clark. *United States Bureau of Mines, Mineral Market Reports* No. M. M. S. 445, Mar. 13, 1936, 1 page. Statistical. AHE (15a)

Aluminum Industry in 1935—Advance Summary. H. W. Davis. *United States Bureau of Mines, Mineral Market Reports* No. M. M. S. 444, Feb. 24, 1936, 2 pages. Statistical. AHE (15a)

South Africa's Base Metals and Minerals. A. L. Hall. *South African Mining & Engineering Journal*, Vol. 46, part II, Nov. 9, 1935, pages 307-308. From address "Base Metal and Mineral Resources of the Union" before Transvaal Workers' Educational Association. Economic. AHE (15a)

The World's Gold and Silver Output. H. M. Lawrie. *South African Mining & Engineering Journal*, Vol. 46, part II, Nov. 9, 1935, pages 309-310. Extracts from "Mineral Industry." AHE (15a)

New Alloys. T. W. Lippert. *Iron Age*, Vol. 137, Jan. 2, 1936, pages 171-174, 176-178, 180, 182. Begins with a brief historical survey of alloy steels. Impetus furnished by automobile requirements was accentuated by the airplane, which depends largely on strong and dependable alloys. The oil and power industries, shipyards, and railroads, are also imposing severe service conditions on available alloys. The low alloy steels are among the most important in transportation field. Some of the low alloy high-tensile steels are Cor-Ten, Man-Ten, Mayari, Yoloy, Konik and many others. In the non-ferrous field Al-Ni type magnets are in production. Another magnet alloy is the Al-Ni-Co type produced by General Electric Co., which is superior to a Japanese alloy developed by Mishima. In Al field a satisfactory free machining alloy was produced. Another alloy on the market is a mixture of high metallic boride crystals and low-C steel. Other alloys developed are Doler-Brass, Mallory 3, Fernico, etc. VSP (15a)

World Steel Output 20.6 Per Cent Higher in 1935. T. W. Lippert. *Iron Age*, Vol. 137, Jan. 2, 1936, pages 98-101. World production of steel ingots and castings represents 20.6% advance over 1934, while the United States advanced about 30.5%. United States exports are lower than they were a few years ago, since many countries that bought steel in this country are becoming self sufficient. Germany established a larger gain in steel production than any other country. Belgium and Luxemburg were the only ones producing less steel in 1935 than in 1934. World pig Fe production was about the same as steel ingots and castings, 72,368,000 gross tons, or 16.6% advance over 1934. Per capita consumption of steel in United States was 446.4 lb. Germany was next with 317.7 lb., and United Kingdom third with 268.8 lb. Belgium and Luxemburg were fourth with 241.9 lb. France fifth with 193.2 lb., and Russia sixth with 130.4 lb. Gives tables and graphs showing world production of steel ingots, castings and pig Fe for a number of years. VSP (15a)

The Steel Industry in 1935. G. L. Lacher. *Iron Age*, Vol. 137, Jan. 2, 1936, pages 45-47, 50-52. Recovery in the industry accelerated in 1935, although the improvement did not mark the return of prosperity. In terms of ingot capacity, steel production was only 48%. Ingot production in 1935 surpassed 1934 by 33%. Though less than half of country's capacity was engaged, operations were much steadier than in 1934 and 1933. Developments that influenced the course of steel production in 1935 were the decision of U. S. Supreme Court declaring the N.R.A. unconstitutional, which seemed to increase recovery, and introduction of new automobiles in November instead of in January. Higher costs of fuel, pig Fe and semi-finished steel made advance of finished products necessary, but fear was expressed that high prices might discourage industries which were just beginning to supply their deferred needs. Labor disturbances tended to discourage various enterprises. Number of changes in steel prices were made. Largest increase in finishing mill capacity was in continuous mills producing sheet and strip steel. Beer cans were introduced. Imports increased, while exports decreased. VSP (15a)

Zinc Industry in 1935—Advance Summary. H. M. Meyer. *United States Bureau of Mines, Mineral Market Reports* No. M. M. S. 427, Jan. 6, 1936, 2 pages. Statistical. AHE (15a)

Blast Furnace Plans and Prospects in the U.S.S.R. B. M. Suslov. *Iron Age*, Vol. 137, Jan. 30, 1936, pages 28-29, 79. According to the second five year plan the Soviet Union is to have an ultra modern and self-sufficient steel industry. Capital required for this plan amounts to 9,340,000,000 roubles. Its distribution is as follows: (1) for completion of construction of metallurgical works begun during the first 5 year plan period, 4,280,000,000 roubles; (2) for construction and repairing of metallurgical works, 3,910,000,000 roubles; (3) for reconstruction and development of Fe ore and Mn ore, 1,150,000,000 roubles. Includes a number of tables. VSP (15a)

Time Studies in Foundry Work. V. Bernard. *Proceedings Institute of British Foundrymen*, Vol. 26, 1932-1933, pages 292-334. See *Metals & Alloys*, Vol. 5, Apr. 1934, page MA 166. CEJ (15a)

FREE SERVICE DEPARTMENT

Wanted:—By a well-known manufacturer of Heat and Acid Resisting Castings Sales Representatives who are acquainted with buyers and operating heads in the Steel, Automobile, Chemical and Oil Industries in the following territories: New York, Boston, Philadelphia, Chicago, Cincinnati, Houston and Birmingham. No objection to one or two more lines. Reply giving references and full information as to qualifications. Address Box MA-2, Care of Metals & Alloys, 330 W. 42nd St., New York, N. Y.

REPRESENTATIVE WANTED—A manufacturer of heat resisting alloys and castings seeks representation in both the Philadelphia and New England territories. We are looking for a manufacturer's representative now calling on metal working plants who has the entree to the heat treating supplies market. Write Box No. MA-3, METALS & ALLOYS, 330 42nd Street, New York, N. Y.

Junior Executive Available—M. I. T. Graduate. General engineering experience, Chase Brass and Copper Company. Purchasing chemicals and equipment, R. H. Macy and Company. Single, Christian, references. Box No. MA-4, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

POSITION WANTED: INSPECTOR, SUPERVISOR or INSTRUCTOR of WELDING. Specialized 8 years in arc welding. Knowledge of Metallography, Heat-Treating and Physical Metallurgy. Capable of performing tests and conducting investigations of Weld-Metal. Sales experience. Member of American Welding Socy. and American Socy. for Metals. Good Linguist. Consider position outside U. S. Available July First. Address box MA-6, care of METALS & ALLOYS, 330 W. 42nd Street, New York, N. Y.

METALLURGIST AVAILABLE.—A young man, a graduate Chemical Engineer now employed, who has had more than seven years of experience covering all phases of both ferrous and non-ferrous physical metallurgy, including a knowledge of materials and their applications, heat treating, metallurgical, physical, and corrosion testing, is seeking a new connection with opportunities for increased responsibility and salary. For further information write to Box MA-8, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

MARKET RESEARCH SPECIALIST with a good technical background. Complete developing and marketing experience on electrical and chemical specialties and instruments. Salary or fee basis. Box MA-9, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

■ 15b. Historical ■

With Hammer and Torch (Med Hammare och Fackla) Seventh Year Book issued by Sancte örjens Gille, Stockholm, Sweden, 1936. Paper, 6¾ x 9¾ inches, 171 pages.

A historic review dealing with the early days of the Swedish mining and metal industry. Of particular interest is a description of the Swedish crucible steel process, written in 1769. Also discusses the Brandt-Winjbladh method of smelting Cu as used at Riddarhyttan smelter about 1690 and describes the efforts made at that time to improve Cu smelting. Tests, over several years were also made by a German metallurgist to effect the transmutation of Fe into Cu and Cu into Ag. Other articles deal with the smelting of Au-Ag ore imported to Sweden from Sumatra about 1600, and the methods of power production and the equipment used for hoisting and hauling at the Grängesberg iron works about 100 years ago. Steel Tempering Superseded. *Edgar Allen News,* Vol. 14, Mar. 1936, pages 815-816. A historical sketch of the discovery in 1870 of the Mushet self-hardening steel, used for tools and dies. Ha (15b)

Seventy-Five Years of the Verein Deutscher Eisenhüttenleute (1860 bis 1935-75 Jahre Verein deutscher Eisenhüttenleute) *Stahl und Eisen,* Vol. 55, Nov. 28, 1935, pages 1253-1450. Anniversary number. Biographical and historical, fully indexed. SE (15b)

Nickel Industry in 1935 (Die Nickelindustrie im Jahre 1935) *Nickel Berichte,* Vol. 6, Jan. 1936, pages 1-5. The utilization of Ni in transportation, chemical industry, rolling mills for ferrous and non-ferrous materials, mining, building, textile, food, electrical industry, agriculture, refrigerating and oil industry is discussed emphasizing progress made in 1935 as reported by R. C. Stanley. EF (15b)

MANUFACTURERS' LITERATURE

Gasifier

A pamphlet devoted to the Stewart gasifier contains the claims that its use reduces fuel costs as much as 75 per cent, produces a true gas of high B.t.u. value and is easier on furnace lining. Illustrated. Chicago Flexible Shaft Co., Chicago, Ill. (789)

Ladle Fluxes

The advantages of using fluxes for aluminum, brass, bronze, copper nickel, iron and special alloys are listed in a leaflet of The Maluminum Co., Indianapolis, Ind. (790)

Blast Cleaning Equipment

A new quick reference catalog of information on the above has a thumb index which provides easy access to specific items. Dust control and modern types of dust collectors, exhaust fans, etc., Pangborn blast machines, blast rooms, blast barrels and blast tables are some of the topics treated in this brochure of the Pangborn Corp., Hagerstown, Md. (791)

Tool Steel

A colorful leaflet devoted to Saratoga oil-hardening, non-shrinking tool steel contains data on analysis, applications and heat treatment. Ludlum Steel Co., Watervliet, N. Y. (792)

Firebrick

The service of Okilo brick covers a wide range of refractory requirements in the second quality field, according to a pamphlet which discusses the high grade raw material with its fineness of grain and plasticity and the process of manufacture which produces durable brick with a clean hard finish. The Pyro Clay Products Co., Oak Hill, O. (793)

Heat Treating Furnaces

The advantages of forced convection heat treating with recirculation are described in a pamphlet devoted to this subject. According to this leaflet heat time is cut tremendously, uniformity within 1 deg. F. can be obtained in the soaking or holding chamber of Morrison engineered continuous furnaces and atmospheres can be controlled within very close limits. The Morrison Engineering Co., Inc., Cleveland, O. (794)

Testing Machines

Bulletin No. 99 gives a description of the development of the Southwark-Heydekampf machine, and an explanation of its principles. This machine has a rotating cylinder wall, load is read as a function of loading cylinder pressure by means of a small auxiliary measuring cylinder to which pressure is carried. Moving of the measuring cylinder ram is resisted by Iso-Elastic springs. Illustrated. Baldwin-Southwark Corp., Philadelphia, Pa. (795)

Heat Treating Furnaces

According to Bulletin No. SC-75 there is a correct type and size SC standard furnace for any heat-treating operation. Several different types are illustrated. Operating data on a few are included. Surface Combustion Corp., Toledo, O. (796)

Truck Body Construction

Through the use of the light, strong alloys of Alcoa Aluminum, bodies have been built which weigh only 35 to 60 per cent as much as they would have if built of heavier structural materials, according to this catalog. A table of recommended alloys for different applications is included. The alloys are available in the form of structural shapes, sheet, plate, rivets, bolts, nuts, castings and forgings. Aluminum Co. of America, Pittsburgh, Pa. (797)

Quenching Machine

In the Greene tank objects are forced apart and kept in motion, solution vigorously sweeps over the objects and cooling is equal on all sides according to a leaflet which contains the statement that a test will demonstrate the better hardening accomplished by this machine. Illustrated. E. G. Greene, Cleveland, O. (798)

Carburizing

A reprint of an article "Continuous Carburizing of Screws with City Gas" by John A. Comstock is being offered by the American Gas Furnace Co., Elizabeth, N. J. (799)

Oil Burners

Catalog No. 360 claims that this company's burners light, handle and control with a degree of facility not found in other burners because of the following features: separate inner tip maintains high air velocity with thorough atomization throughout working range; combination of inner and outer air tips gives control of length and character of flame and permits adjustment and operation with automatic control, etc. W. S. Rockwell Co., New York, N. Y. (800)

Thermometers

Catalog No. 1250 is devoted to thermometers (recording, controlling and indicating) which are modern in all respects, representing the latest developments in the field of temperature measurement, yet old in principle. Illustrations, scales and charts included, as well as a table of contents. Bristol Company, Waterbury, Conn. (801)

Micromax Thermocouple Pyrometers

A new catalog, N-33A, explains the potentiometer method of measurement, the operation of the mechanisms through which this balance method is made available to industry. The new Silver-Anniversary Micromax is described in detail. It keeps ten inches of record always visible, while a bold pointer enables the operator to read temperature at a glance. The complete line of instruments is set forth. Leeds & Northrup Co., Philadelphia, Pa. (802)

Flame-Otrol

This automatic gas shut off which is simple, positive in operation and operates with split second speed, according to the manufacturer, is the subject of an illustrated pamphlet. Wheelco Instruments Co., Chicago, Ill. (803)

Polishing Machines

A portable model and a floor model of these new metallographic machines are described and illustrated in a pamphlet from Eberbach & Son Co., Inc., Ann Arbor, Mich. (804)

Furnaces

Information concerning Hausfeld modern melting equipment for die casting is featured in an illustrated leaflet. These furnaces are made interchangeable for oil or gas fuel. Campbell-Hausfeld Co., Harrison, O. (805)

Research Puts the Diatom to Work

This booklet discusses the history of the diatom from which Celite is made. The four main industrial services of Celite: high temperature insulation, a filter aid, mineral filler and workability agent in concrete are described. Illustrated. Johns-Manville, New York, N. Y. (806)

Sicromo Steel

High temperature data sheets containing full information on this steel have been issued by The Timken Steel & Tube Co., Canton, O. (807)

Coreless Induction Furnace

A colorful leaflet contains an explanation of the principle of operation and advantages to be obtained from the use of the Ajax-Northrup electric furnaces. Ajax Electrothermic Corp., Trenton, N. J. (808)

Spectrometric Equipment

Catalog D-221 is devoted to the above equipment. Basic theory and design are described as well as the various types of instruments. Illustrated. Bausch & Lomb Optical Co., Rochester, N. Y. (809)

Cutting Oils

A leaflet is devoted to the EFHCut series of oils. It is claimed that this series represents the best straight cutting oils obtainable, at a price which meets and beats competition. E. F. Houghton & Co., Philadelphia, Pa. (810)

Industrial Furnaces

This catalog describes, illustrates and gives specifications for furnaces suitable for various applications. Mahr Manufacturing Co., Minneapolis, Minn. (811)

Aerocase

Booklet on this subject. Illustrations, curve charts, tables. American Cyanamid and Chemical Corp., New York, N. Y. (812)

Monel Metal and Nickel

Bulletin C-4 is devoted to the use of these metals in the manufacture of pharmaceuticals, fine chemicals and proprietary products. International Nickel Co., Inc., New York, N. Y. (813)

The Jetal Process

Simple immersion in an aqueous bath for about 5 minutes colors all grades of common iron or steel a brilliant and uniform jet black. It is claimed it does not alter dimensions of articles and cannot chip, scale, peel or discolor. Alrose Chemical Co., Providence, R. I. (814)

Potentiometer Controllers

Bulletin No. 202 covers the complete line of potentiometer and resistance thermometer controllers. A number of simplified wiring diagrams showing how an installation looks are included. Foxboro Company, Foxboro, Mass. (815)

MANUFACTURERS' LITERATURE

Refractory Cement

Bulletin No. 317, describes Q-Chrome neutral-base refractory cement which was designed for severe-service duty. Quigley Company, Inc., New York, N. Y. (816)

Chapmanizing

A pamphlet devoted to Chapmanizing, which is a process of hardening low-carbon steel, compares it to nitriding and carburizing. The Chapman Valve Mfg. Co., Indian Orchard, Mass. (817)

Sonittep Products

This booklet discusses heat loss and its control. The advantage of Sonittep insulating cement and its uses are listed. Instructions for its application are included. Graphs. George F. Pettinos, Inc., Philadelphia, Pa. (818)

Dolomite Refractories

This interesting pamphlet presents the case of Clinkered vs. Calcined Dolomite in the basic open-hearth steel furnace. Basic-Dolomite, Inc., Cleveland, O. (819)

Mallory Elkon

Looseleaf catalog containing engineering data with descriptions, illustrations and recommendations for the selection of electrical contacts for all types of service. P. R. Mallory & Co., Inc., Indianapolis, Ind. (820)

Flex-Arc Rays

Data bulletins containing information on arc welding are published by the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa. (821)

Armco H.T.-50

An illustrated folder devoted to the above alloy steel contains data on the average physical properties, corrosion resistance and forming and welding qualities. American Rolling Mill Co., Middletown, O. (822)

Alloy Steels

A colorful folder devoted to these steels lists some of the advantages to be obtained by their use. Bliss & Laughlin, Inc., Harvey, Ill. (823)

Wheelabrator Tum-Blast Cleaner

This cleaner, which it is claimed sets the highest standard of efficiency ever attained in an abrasive cleaning machine is a combination of the Tum-Blast Cleaner and the Wheelabrator. Book 111 is devoted to it. American Foundry Equipment Co., Mishawaka, Ind. (824)

Heat Exchanger

Bulletin No. 173 describes the Duriron heat exchanger which is available in the company's corrosion-resisting alloys—Duriron, Durichlor, Durimet, Durco Alloy Steel and Alcumite. Illustrated. Duriron Co., Dayton, O. (825)

Wet Patch

The manufacturer claims that excellent results are obtained when P. B. Sillimanite wet patch is used to patch crucible furnaces, electric furnaces, etc., because of its high refractoriness, negligible shrinkage and stubborn resistance to slag attack. The Chas. Taylor Sons Co., Cincinnati, O. (826)

Electric Welding Products

Catalog No. 101 contains information on welding rods (recommended uses for the different types, physical properties, welding procedure, etc.); miscellaneous apparatus, and Wilson arc welding machines. Air Reduction Sales Co., New York, N. Y. (827)

Inhibitor

Grasselli 3 inhibitor for efficient, economical pickling is the subject of a booklet of The Grasselli Chemical Co., Inc., Cleveland, O. (828)

Hi-Steel

Information concerning chemical composition, physical properties and corrosion resistance of this steel is offered by the Inland Steel Company, Chicago, Ill. (829)

Zinc Alloy Die Castings

A technical booklet tells the story of the development of the "Zamak" alloys. Tables and illustrations. New Jersey Zinc Co., New York, N. Y. (830)

Dowmetal Data Book

A new edition of this book, containing especially significant accomplishments since the last data book, in the sections Available Forms and Shop Practice, has been published by The Dow Chemical Co., Midland, Mich. (831)

Vanadium Facts

Another issue of this publication contains accounts of progress and performance in the field of alloy steels. Vanadium Corp. of America, New York, N. Y. (832)

Optical Pyrometer

The Burrell optical pyrometer, a direct reading instrument originally designed for use with the Barrett fusion furnace and equally useful for other work requiring an optical pyrometer with a temperature range from 1500 to 3000 deg. F., is described and illustrated in a leaflet published by the Burrell Technical Supply Co., Pittsburgh, Pa. (833)

Phosphor Bronze

A leaflet lists the sizes in which the company's twelve-inch stock bushing bars are now offered. The Phosphor-Bronze Smelting Co., Philadelphia, Pa. (834)

Permite Six Foot Cast Bronze Bars

An attractive booklet states that these bars assure a product identical in physical and wear resisting qualities with the finest individual castings. Joseph T. Ryerson and Son, Inc., Chicago, Ill. (835)

Sand Control in the Foundry

A colorful pamphlet lists the major causes of casting defects and inferiorities and states that they may be avoided by the use of the proper sand control equipment. Illustrated. Harry W. Dietert Co., Detroit, Mich.

Published by the same company: "The Core Maker"—a leaflet and "Deformation and Resilience Accessory for Universal Sand Strength Machine"—looseleaf data sheet. (836)

Heat and Corrosion Resistant Alloys Heated By Gas

Bulletin C1-A illustrates a number of complex castings made from Q-Alloys which are recommended for pipe fittings, furnace parts, etc. General Alloys Co., South Boston, Mass. (837)

MoTung High Speed Steel

An illustrated booklet devoted to the above, contains information under these divisions: working and treatment, surface protection, high heat temperatures, drawing temperatures, effect of treatment, etc. An index is included. Universal Steel Co., Bridgeville, Pa., and Cyclops Steel Co., Titusville, Pa. (838)

Temperature Control Instruments

Bulletin 33 is devoted to instruments for automatic control of temperatures in industrial furnaces. Illustrated. American Electric Furnace Co., Boston, Mass. (839)

Controlled Grain Anodes

Seymour Nickel Anodes are homogeneous in grain structure, according to this bulletin. The various available shapes are illustrated and some useful data are given. The Seymour Manufacturing Co., Seymour, Conn. (840)

Granite City HS Grades 1 and 2

Information concerning the Granite City manganese high tensile steels can be obtained from the Granite City Steel Co., Granite City, Ill. (841)

Gas Fired Furnace

The manufacturer of the gas fired Lindberg Cyclone furnace for heating at temperatures from 250 deg. F. to 1400 deg. F. claims that the heating rate is remarkably fast, and either open or extremely dense charges are handled with equal facility. The principle of the furnace is described in Bulletin 51. Illustrations. Lindberg Engineering Co., Chicago, Ill. (842)

Air Operated Control Instruments

A colorful pamphlet devoted to the Air-O-Line controllers contains the statement that engineers like it because it insures maximum accuracy; it is easily adapted to any process control requirement as the throttling range and automatic reset dials are easily accessible and can be reached without removing the chart plate and taking the instrument off control; the balanced bellows system insures exact control point setting; and it is rugged. Illustrated. Brown Instrument Co., Philadelphia, Pa. (843)

Braze-Rite Furnace

This furnace, developed principally for brazing sintered carbide cutting tools, provides for localized heat to be applied only to the portion of the tool to be brazed. The sintered carbide blank to be brazed in place is merely laid onto the shank and after the proper heat has been obtained the blank is firmly pressed onto the shank—all controlled under a hydrogen atmosphere. Illustrated. Firth-Sterling Steel Co., McKeesport, Pa. (844)

Radium for Industrial Radiography

This article written by R. A. Gezelius and C. W. Briggs, containing interesting and important information on the subject, is published in handy booklet form. Radon Company, Inc., New York, N. Y. (845)

A. W. 70-90

This bulletin describes the new high-strength "70-90" steel in sheets and plates. An article on the engineering aspect of high-strength sheet steels is included. Alan Wood Steel Co., Conshohocken, Pa. (846)

CURRENT NEWS ITEMS

Ford Installs the Largest Continuous Electric Furnace

The Ford Motor Co. has purchased from the Westinghouse Electric & Mfg. Co., a 325-ft. long, controlled atmosphere continuous roller hearth furnace for bright normalizing automobile body stock in a continuous strand or in strip. The output of this furnace will be 7½ tons per hr., based on 56-in. wide strip. This is the largest continuous electric furnace in the world. The Ford company already has a 227-ft. long furnace of this type, which it purchased from the Westinghouse company and which has been in operation for about a year.

The rating of the furnace is 2335 kw of which 1920 kw is in the first heating chamber and the remaining 415 kw in the reheating chamber following the first cooling chamber. The strip will be heated in the first chamber to approximately 1750 deg. F. and can be cooled to a maximum of 800 deg. F. in the first cooling chamber. The reheating chamber is amply rated to heat the strip from 800 to 1300 deg. F. if desired and the cooling chamber following is capable of cooling the strip down to 250 deg. F. before it is exposed to the air. Accordingly the furnace is being built to provide for considerable variation in the cycle to obtain the maximum ductility and softness which may be accomplished in a relatively short cycle.

Battelle Adds to Its Staff

Battelle Memorial Institute, Columbus, Ohio, announces the appointment of Dimitry Niconoff, J. G. Donaldson and L. H. Berkelhamer to the technical staff. Mr. Niconoff, who was formerly metallurgist for the Phelps-Dodge Corp., has been assigned to the division of process metallurgy. Mr. Donaldson, who comes to Battelle from the Laclede Steel Co., has been assigned to the chemical division and Mr. Berkelhamer, who was formerly a Bureau of Mines Fellow at the University of Washington, to the ceramics division.

Nickel Co. Expands at Huntington

Increasing interest by industry in the non-ferrous alloys as a weapon against rust and other forms of corrosion has made necessary an enlargement of the laboratory facilities at the Huntington, W. Va., plant of The International Nickel Co., Inc., according to Robert C. Stanley, president. He has also announced that new administrative offices would be built and that a new unit would be added to the open-hearth furnaces.

The plant, which produces monel metal, pure nickel and Inconel in commercial shapes, is now operating at approximately the 1929 level, he said; and a 25-ton open-hearth furnace will be built to bring ingot production in balance with the capacity of the rolling mills. A three-story brick administration building is being erected for the executive offices and the chemical and physical laboratories are being enlarged.

The **Mahr Mfg. Co.,** Minneapolis, announces the appointment of Gerald B. Duff, 39 Oxford St., Newark, N. J., as its representative for that territory. It has also appointed the Fuchs Machinery & Supply Co., 1102 Farnam St., Omaha, Neb., as its representative for the territory surrounding Omaha.

The **Lea Mfg. Co.,** Waterbury, Conn., has added a complete line of sawdust to its already extensive line of platers' supplies. It is carrying hardwood, kiln dried sawdust ranging from the finest to the coarsest.

The appointment of **Arno C. Fieldner** as chief of the technologic branch of the United States Bureau of Mines, Department of the Interior, is announced by Dr. John W. Finch, director of the Bureau. Mr. Fieldner succeeds O. P. Hood, who recently retired after a long period of service.

Promotions by Tagliabue Mfg. Co.

The C. J. Tagliabue Mfg. Co., Brooklyn, manufacturers of indicating, recording and controlling instruments, has announced the promotion of A. F. Rucks to the position of general manager. Mr. Rucks has been associated with the Tagliabue company for over 23 yrs., and has had extended experience in practically every phase of the Tagliabue company's industrial instrument business.

The company also announces the appointment of W. C. Bennett as general sales manager in charge of the eastern territories, and E. D. Wacker as general sales manager in charge of the western territories. Both Messrs. Bennett and Wacker will spend a considerable portion of their time in the field.

Carboloy Announces Staff Changes

Carboloy Co., Inc., Detroit, manufacturers of Carboloy cemented carbide tools, dies and wheel dressers, recently announced the following changes in, and additions to, the personnel of the organization:

P. R. Mallory, former chairman of the board, has resigned. He is succeeded by Dr. Zay Jeffries, former president. W. G. Robbins and E. S. Morrison have been elected to the board of directors.

W. G. Robbins, former vice-president and general sales manager, has been elected president. A. MacKenzie, former manager of manufacturing, has been elected vice-president in charge of manufacturing. K. R. Beardslee, former Pittsburgh District sales manager, has been appointed general sales manager of the Carboloy company. J. R. Longwell, former die engineer, has been appointed chief engineer. A. A. Merry, former Cleveland District sales manager, has been appointed special representative in charge of activities with agents licensed to supply Carboloy on their tools, dies and machines.

A. H. Godfrey, former Cleveland representative, has been appointed Cleveland District manager. P. W. Weiser, former Pittsburgh representative, has been appointed district manager of the Pittsburgh District.

Steel Engineers to Hold Convention

Every phase of steel mill operations will be discussed in 35 technical papers to be presented at the 32nd annual meeting of the Association of Iron and Steel Engineers at the Hotel Statler, Detroit, Sept. 22 to 25. Representatives of companies which manufacture sheet and strip steel and of companies which are prominent in the application and use of steel in this form will be given one full day for the presentation of papers on that topic. Inspection trips through the new strip mills of the Great Lakes Steel Corp., and the Ford Motor Co., will supplement the discussions.

M. E. Leeds Honored

M. E. Leeds, president of the Leeds & Northrup Co., Philadelphia, recently received, almost coincidentally, two signal honors: The Institute of Management gave him its Gantt Medal for "distinguished achievement in industrial management as a service to the community" and Polytechnic Institute of Brooklyn made him Doctor of Engineering "in recognition of great service to society."

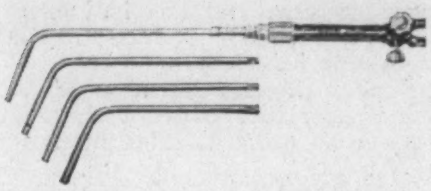
C. Q. Swenson has been appointed Michigan representative by the **Michiana Products Corp.,** Michigan City, Ind., makers of stainless and heat-resistant alloy steel castings. Mr. Swenson is a metallurgist who has had considerable practical experience in the heat-treating industry in the Detroit and Michigan territory for many years. His offices are located at 2842 W. Grand Blvd., Detroit.

R. R. LaPelle has recently become associated with the **Salem Engineering Co.,** Salem, Ohio. He was formerly associated with The Electric Furnace Co., as sales engineer and was more recently section engineer in charge of furnace design for the Westinghouse Electric & Mfg. Co.

NEW EQUIPMENT AND MATERIALS

Light Weight Welding Torch

The Modern Engineering Co., St. Louis, makers of "Meco" oxy-acetylene welding equipment, is in production on its new "Weldmaster" ultra-light weight welding torch. This torch with a standard tip weighs only 17½ oz. and is claimed by the makers to be the lightest weight torch on the market.



A new alloy that can be forged, extruded and heat treated and has a tensile strength of mild steel is used in the construction. According to the makers, the torch is perfectly balanced as a result of weight elimination and can be manipulated by the operator with maximum flexibility and minimum effort.

The circle mixer employed in all Meco torches has been improved and its capacity increased. Even the largest tips may be used efficiently with low gas pressures, as when working from medium acetylene generators. A new method of boring passages to rifle smoothness has been developed in this torch. Ideal flame characteristics under any operating circumstances in the full range of welding practice are claimed. These torches are made in two types, the standard and the super.

Protective Coating Material to Prevent Carburizing

K-Seal, a product of the Lindberg Engineering Co., Chicago, offers important advantages in steel treating operations where it is necessary to limit the carburizing action to certain areas. It is supplied in the form of a powder and a liquid which are mixed in definite proportions as used. When applied to the surface of steel, properly cleaned and free from oil, before the carburizing treatment, this protective coating will entirely prevent the penetration of carbon.

For example, if machining or straightening is to be done on a particular part while in a hardened condition, the application of K-Seal before carburizing will keep the painted section soft at the point where the machining or straightening is to be performed. The material adheres firmly to the steel surface, so that very sharp boundaries can be obtained between the areas of full penetration and the painted areas where there is a total absence of additional carbon.

This useful material is claimed to provide a simple solution to many heat-treating problems and to open up new possibilities in the design and fabrication of machine parts.

Enamel Finish for Die Castings

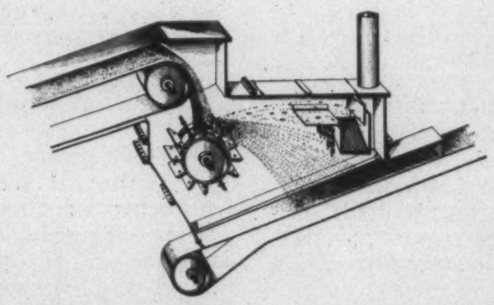
The difficult problem of developing an enamel finish that will adhere tenaciously and continuously to zinc has been successfully solved by Maas & Waldstein Co., makers of lacquers and lacquer enamels, Newark, N. J., according to an announcement by that company. As a result of its research work the company is now placing on the market a new line of air-drying lacquer enamels which are especially designed for finishing zinc and aluminum die castings. These new die-casting lacquer enamels are claimed to produce an excellent, durable, elastic finish in one coat. They are supplied in gloss and egg-shell sheens and in white, black, and 32 standard shades. Special colors can be supplied when desired.

A New Foundry Sand Aerating, Separating Unit

Announcement is made by Link-Belt Co., Philadelphia, Chicago, that it has placed on the market a new foundry sand preparation unit, known as the Link-Belt "Sep-Aerator" because it performs automatically the two-fold function of, (1), properly aerating and mixing the sand before delivery to molder's hoppers, and, (2), separating from the sand, such shot metal, pebbles and small refuse as may not have been caught by screen or magnetic pulley. This separating feature is of particular value in non-ferrous foundries, where it is not possible to remove metallic shot by magnetic attraction.

The "Sep-Aerator" is a high-capacity unit, which is said to be ideally suited for continuous mechanical handling systems, and supplements the Link-Belt line of sand revivifiers. The several installations that have been made have shown that the amount of refuse removed each time that the sand passes through the machine, makes the installation one that assists greatly in the foundryman's desire to produce better castings at lower cost.

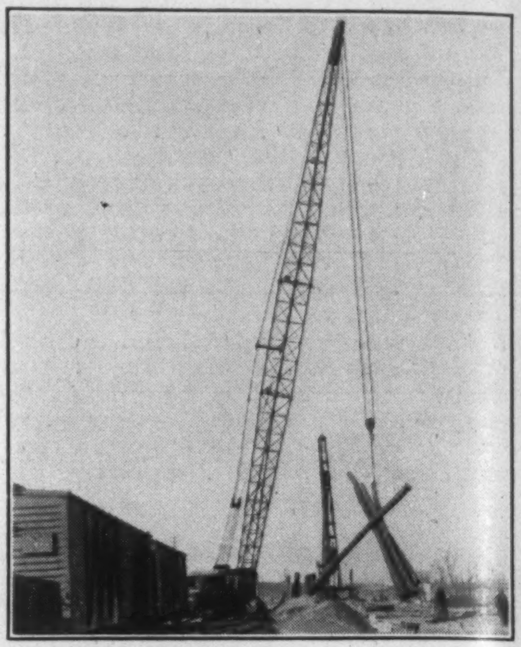
The operating principle is revealed in the illustration, which also shows that the unit is one of few parts—a power-driven paddle-type beater, with sand and refuse collecting and discharging media, all enclosed within a steel housing, which is fitted with an air-release pipe and other suitable means for preventing any blast of air along belt conveyor which receives and carries the aerated sand away from underneath the machine, to the respective molder's storage hoppers.



The position of beater shaft can be adjusted horizontally as required to give proper control of direction of the sand stream. After the beater shaft has been correctly located, the flow regulating plate is adjusted to split the stream of sand and refuse at the desired point. As the refuse travels forward, close to the top of Sep-Aerator housing, it is deflected by a baffle, which permits escape of air currents and assures delivery of refuse to its chute. A shield of chains in front of the refuse chute keeps the sand from building up at this point. A screen bottom in refuse chute permits any sand, traveling with the refuse, being diverted to the aerated-sand conveyor.

A Light, Welded Tube Boom for Cranes

The remarkably long boom of this P&H Model 575 crawler crane was designed by the Harnischfeger Corp., Milwaukee, especially for the extremely high lift required for the erection of catenary towers to carry electric power lines. In contrast with the standard boom of structural steel which weighs 125½ lbs. per ft., this boom, arc welded of tubular steel, weighs only 75½ lbs. per ft. and provides a reach of 100 ft. The lightness of this boom makes it possible for the machine to lift normal loads more than 80 ft. high without undue tipping strains.



New Model Incandescent Lamp Blueprinter

Another model has been added to the line of Angstrom lamp "Blueprinters." This one is double the size of previous models, viz., 24 by 36 in., and has been developed to supply the needs of those whose work could not be handled on the 18 by 24 in. sizes.

Essential features of the older model are all retained, including the use of incandescent lamps as a light source and elimination of the belt feed by the flat bed printing surface.

A timing switch of the heavy duty type has been developed for automatically breaking the heavier current and forced ventilation is supplied to prevent any tendency to overheat. Both of these features are also available on the smaller machine.

The same economy of operation is claimed for the new model with a cost for prints approximating 1.3c per sq. ft. The Blueprinter is manufactured by Milligan & Wright Co., 1231 West Third St., Cleveland.

"Kwik-Cote" Copper Plate Solution

This product was developed originally by Grapho Products, Inc., 2232 Alvord St., Indianapolis, Ind., to lower the cost of plating where selective hardening is necessary. "Kwik-Cote" is a chemical compound which deposits a copper plating on the part to be treated by dipping or painting with a small stiff brush. Hair-line separation of hardness can be secured with positive results.

With Kwik-Cote any portion of the part to be hardened can be treated.

Preparation for hardening takes but a few minutes as the solution dries almost at once and can be placed in the carburizing pots immediately. A scleroscope hardness variation from 80 to 30 is secured. Threads treated with Kwik-Cote may be kept dead soft and in perfect condition while the remainder of the piece is hardened. Only the parts to be kept soft are treated.

It may be used between cams, back of gears, threads, in bores where stock is left for reaming after heat treating, on springs and any section to be kept soft. The solution may be used as a base for nickel or chrome plating. The work is thoroughly cleaned, dipped in the solution, the surplus liquid washed off and is ready for plating.

New Line of Controllers

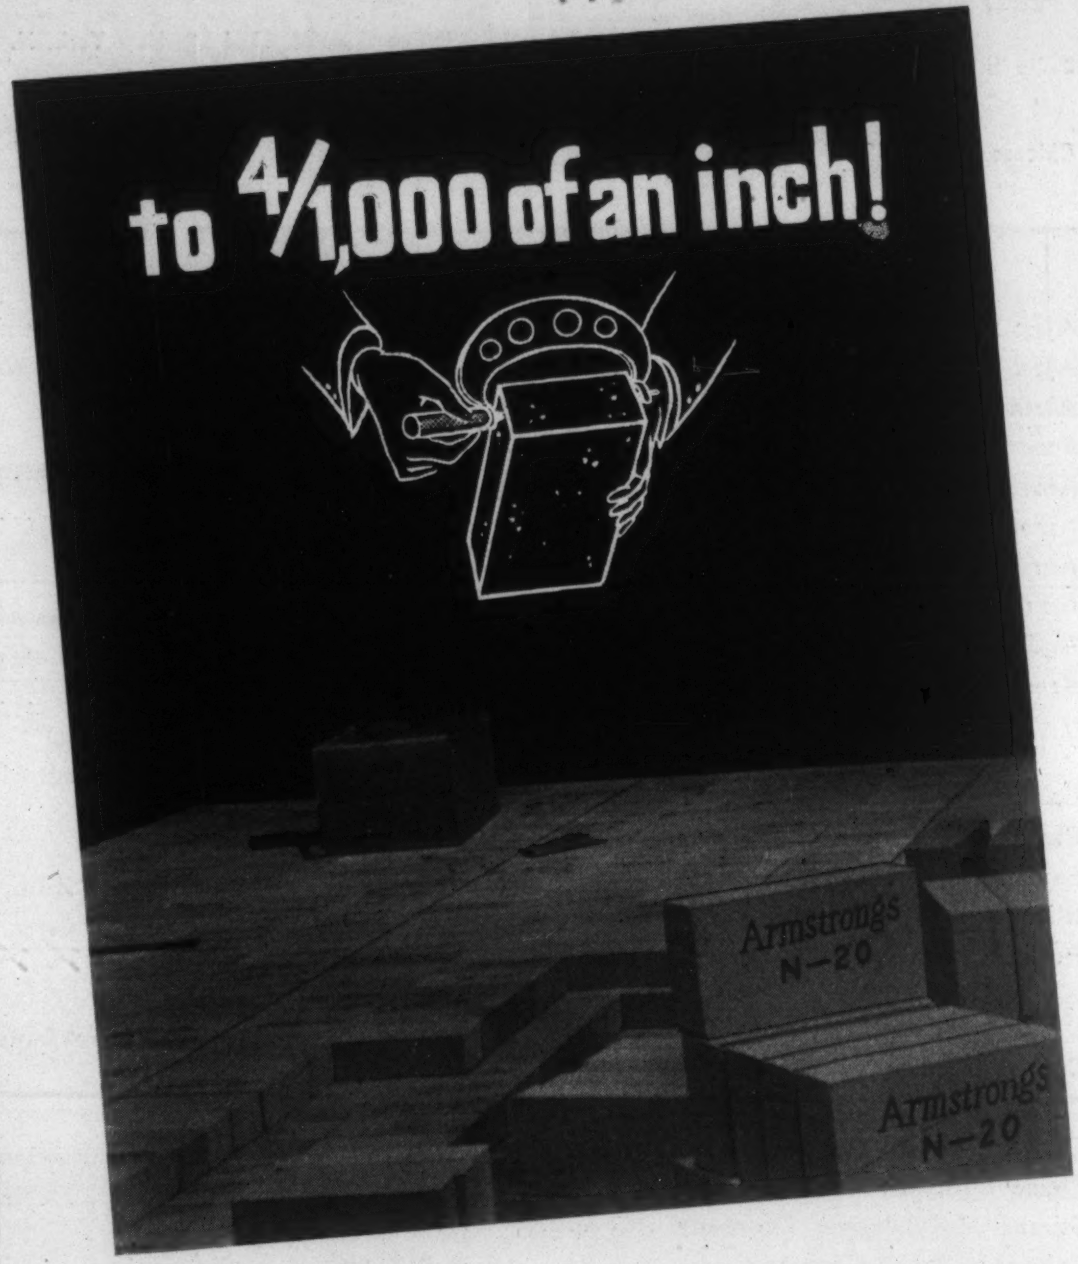
A new line of controllers for temperature, time-temperature, flow, liquid level, pressure, time-pressure, and humidity is announced by The Bristol Co., Waterbury, Conn. These controllers, known as "Master Free-Vane Controllers" are offered primarily for applications where a greatly reduced sensitivity (wide throttling range) is required and the load conditions fluctuate over a wide range.

The Master Free-Vane Controller is a pneumatic-type controller operating on Bristol's free-vane principle of control. It is similar in many respects to the new Ampliset controller, an instrument equipped with a sensitivity adjustment, announced by this company recently.

In the Master Free-Vane Controller the basic free-vane system is equipped with a sensitivity adjustment, an automatic reset, and accessory features which minimize hunting; prevent departure from the control setting; make it possible to reach a new control setting without over-shooting; to adjust the anticipatory effect to fit the process lag; and to adjust the resetting mechanism to function in an amount proportional to the rate of change in the process.

The Master Free-Vane Controller is offered primarily to take care of more severe conditions encountered in processes, such as sudden load changes, over-shooting, etc. It is designed to automatically compensate for each of the disturbing elements in industrial processes that, from time to time, have a tendency to upset the true function of the control system. It also makes it possible to obtain precision control on extremely difficult applications without assistance from the operator. Moreover, it is a self-contained instrument of quite simple design with all parts contained in one case.

ACCURATELY SIZED



That's why Armstrong's Brick insure a *heat-tight* job every time.

THE picture above *shows*—better than words can tell—what the firm, straight edges and true size of Armstrong's Brick mean in giving you tighter joints when laid dry! Even when laid with cement, these uniform brick permit a much thinner joint! And in both cases, they cut down laying time . . . provide increased construction strength!

The work shown is the base of a box-type annealing furnace recently completed for a large steel company. The bottom is insulated with two layers of 2½" Armstrong's Insulating Brick, the sidewalls and arch with a single layer of the same efficient brick.

In addition to accurate sizing, Armstrong's Brick offer the further advantages of high crushing strength, low thermal conductivity, and freedom from shrinkage. Armstrong's Insulating Brick and Insulating Fire Brick are available in a full range of service and temperature requirements.

Write today for our illustrated folder "Armstrong's High Temperature Insulation for All Types of Heated Equipment." Armstrong Cork Products Company, Building Materials Division, 982 Concord Street, Lancaster, Penna.

1. ORE CONCENTRATION

JOHN ATTWOOD, SECTION EDITOR

A New Gold Producer in Roumania.—Telluride Ore Dressing at the New Sacaramb-Nagyag Mine (Ein neuer Golderzeuger in Rumänien.—Das Bergwerk von Sacaramb-Nagyag und die Aufbereitung seiner Goldtellurerze) Herbert Sommerlatte. *Metall und Erz,* Vol. 33, Mar. 1936, pages 137-142. Roumanian gold-mining in the past year has been pushed zealously. Waste heaps and gobbing residues, containing enough Au to justify reworking have been mixed with crude ore and reworked in modern flotation plants. The yield of Au varied between 75 and 90%. Complete description of plants, with grades and analyses of ore is given. FPP (1)

Developments in German Iron Ore Mining (Über die Entwicklung des deutschen Eisenerzbergbaues) W. Luyken. *Metall und Erz,* Vol. 33, Jan. 1936, pages 2-11. Historical and statistical review of economic and technological developments in German Fe ore mining since 1913 is presented. Germany's practical self-sufficiency with respect to Fe ore, and the extent to which development of various individual geographical districts has furthered this, is discussed. The most important recent development has been a process for utilizing low-grade ore. FPP (1)

1e. Amalgamation, Cyanidation & Leaching

Utilization of Talitter Copper Shale (Zur Nutzbarmachung des Kupferschiefers von Talitter) H. Wölbling. *Metall und Erz,* Vol. 33, Mar. 1936, pages 143-144. A method is described for working Ca rich Cu shales such as the Talitter deposits, by ammonia-leaching. More than 90% of the Cu content can be extracted quickly and cheaply. The extraction residue may be marketed as lime fertilizer to offset the cost of production. FPP (1e)

Modern Metallurgical Practice on the Witwatersrand. T. K. Prentice. *Bulletin, Institution of Mining & Metallurgy,* No. 367, Apr. 1935, 1935, 44 pages; No. 368, May 1935, pages 1-19; No. 369, June 1935, page 33; No. 370, July 1935, pages 1-2; No. 373, Oct. 1935, page 1; No. 376, Jan. 1936, pages 31-38. On the Witwatersrand there are 38 large reduction plants with an average milling capacity of approximately 87,000 tons/mo. each. The last 6 to be erected did not incorporate either stamps or sand treatment units; capital costs were reduced. In the last 5 years 3 new plants were built. Modern high-speed gyratory crushers prepare the feed for the tube mills in the new plants. In 2, milling is in cyanide solution, in the other, in water. In all, Dorr classifiers of the straight drag of the bowl types are used exclusively for classification. Only 1, with the richest ore, has installed corduroy tables for removal of Au from the tube-mill circuit for amalgamation; the others depend entirely on cyanidation. Each uses the Crowe-Merrill vacuum filter leaf method of Zn-dust precipitation. In the Central Mines-Rand Mines group, 1 ton of —100-mesh product by the crusher-stamp and tube-mill combination cost 20.6d.; by the modern crusher-tube mill combination, 19.9d.; costs of 1 ton of —200-mesh material was 29.7 and 28.3d., respectively, by the 2 methods. Cost of cyaniding in an all-sliming plant was 12.3 d./ton; in plants with a sand and slime treatment, 13.6d. Recovery is 92-98%. Cyanide consumption is 0.16-0.50 lb./ton milled. The various steps are discussed with a historical review of metallurgical developments. AHE (1e)

Notes on Ore Pulp Settlement and Filtration, in Cyanidation of Gold Ores. R. J. Lemmon. *Proceedings Australasian Institute of Mining & Metallurgy* No. 98, June 30, 1935, pages 349-356. The constituents in ore and water that affect settlement, filtration and Au extraction are discussed. Flocculators and precipitants in common use include lime, soda ash, $BaSO_4$, and Na aluminate. For deflocculation, NaCN, Na silicate, caustic soda, etc. are employed, according to the ore pulp constitution. AHE (1e)

2. ORE REDUCTION

A. H. EMERY, SECTION EDITOR

Influence of Various Metals and Metal Oxides on the Decomposition of CO (Der Einfluss verschiedener Metalle und Metalloxyde auf die Kohlenoxydspaltung) W. Baukloh & G. Hieber. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 226, Mar. 17, 1936, pages 321-332. Commercially pure powders of Fe_2O_3, Fe_3O_4, Fe, Co_3O_4, Co, Ni_2O_3, NiO, Ni, Cr_2O_3, Cr, Mn_3O_4, Mn, Al_2O_3, Al, ZnO, Zn, CuO were heated at various temperatures in an electric furnace with dry CO passing over the samples contained in a boat. Curves are given for total increase in weight due to C formation versus time, periodic formation of C versus time and C formation versus temperatures between 350° and 750° C. The indications are that Fe catalyzes the CO decomposition. With Co_3O_4 and Co there is increasing CO decomposition up to 650° C. and at 550° C. where the $\alpha \rightarrow \beta$ transformation occurs there is a dip in the decomposition versus temperature curves indicating the loss of catalytic activity at transformation point. Contradictory results were obtained with Ni and its oxides. Cr gave only slight CO decomposition, Mn_3O_4 none, and Mn considerable. Al gives slight C formation and Al_2O_3 none. In reduction of an ore with CO the solid sample distintegrated due to internal C formation. WB (2)

2a. Non-Ferrous

Electrolytic Refining of a Gold-containing Crude Silver Ore Contaminated with Lead and Selenium, Without Preliminary Treatment (Raffination eines vor allem mit Blei und Selen verunreinigten goldhaltigen Rohsilbers auf electrolytischem Wege ohne vorhergehende Feinbrennung) Gotthard Lenk. *Metall und Erz,* Vol. 33, Apr. 1936, pages 201-207. An extensive discussion of electrolytic refining of crude Ag containing 1 — 6% Au, 1.25 — 2.4% Pb and 1.0 — 1.8% Se, as compared with other methods of treatment. Process flow charts are included. FPP (2a)

Smelting in the Lead Blast Furnace. Handling Zinciferous Charges. G. L. Oldright & Virgil Miller. *Metal Industry,* London, Vol. 46, Jan. 25, 1935, pages 122-124; Feb. 8, 1935, pages 173-175; Apr. 26, 1935, pages 460-463; Aug. 2, 1935, pages 112-114; Aug. 9, 1935, pages 139-141; Aug. 23, 1935, pages 182-184; Aug. 30, 1935, pages 204-208. Condensed versions of *U. S. Bureau of Mines Report of Investigations* 3244, 3245 and 3246. See *Metals & Alloys,* Vol. 7, May 1936, page MA 226L/2. HBG (2a)

Bauxite-Soda Versus Bauxite-Soda-Lime Charge. A. N. Varshavskii. *Legkie Metallui,* Vol. 4, Sept. 1935, pages 46-52. In Russian. Substitution of a bauxite-soda charge at the Volkhov Alumina Plant for the bauxite-soda-lime charge used at present would increase the cost and decrease extraction. HWR (2a)

Production of Aluminum Sulphide. A. I. Belyaev, A. I. Lainer & E. I. Khazanov. *Legkie Metallui,* Vol. 4, Sept. 1935, pages 1-14. In Russian. Bauxite, pyrite, Zn blende, and coke were fused together in an electric arc furnace. The slag obtained contained up to 66% Al_2S_2. HWR (2a)

Current Density During Electrolysis of Magnesium from Carnallite. A. Y. Taitz. *Legkie Metallui,* Vol. 4, Sept. 1935, pages 14-22. In Russian. Varying the current density between 0.5 and 2.0 amp./cm.² does not change the current efficiency. HWR (2a)

The Thermal Diagram for the System:—FeS-Cu_2S. With a Note on the Determination of the Dissociation Pressure of Iron Sulphides. D. D. Howat. *Journal Royal Technical College,* Vol. 3, Jan. 1936, pages 587-598. A thermal diagram which has been constructed from a consideration of both thermal and microscopic evidence is put forward for the system FeS-Cu_2S, and shows limited solubility of both constituents with the formation of a eutectic. Cu_2S is soluble in FeS up to 20% and FeS in Cu_2S up to 40% at 970° C. The eutectic temperature is 970° C. and the composition 61% Fe, 39% Cu_2S. A method is also suggested for the measurement of the dissociation pressures of Fe-sulphide mixtures by means of the reduction of the sulphides with H. JWD (2a)

Electrolytic Zinc Produced from Zinc Fumes Obtained from Lead Furnace Slags at Trail, B. C. (Zinc électrolytique obtenu des fumées de zinc provenant des scories de fours à plomb à Trail (Colombie Britannique)) W. H. Hannay & James Bryden. *Revue de Métallurgie,* Vol. 33, May 1936, pages 314-317. Abstract from Canadian Institute of Mining & Metallurgy, Vol. 37, 1934, page 141. See *Metals & Alloys,* Vol. 5, July 1934, page MA 311. JDG (2a)

Treating Zinc Electrolysis Residues and Lead Furnace Slags in Furnaces in Which Ash Is Fused (Le traitement au gazogène à fusion de cendres des résidus de l'électrolyse du zinc et des scories de fours à plomb) J. Van Oirbeek. *Revue de Métallurgie,* Vol. 33, May 1936, pages 303-308. Abstract of the paper delivered before 7th International Congress of Mining & Metallurgy in Paris. At Viviez plant of the Societe de la Vielle Montagne a plant has been operated for 7 years handling about 190 tons/day of residues. It is a modification of a shaft furnace. Preheated air is introduced through tuyeres. Coke and briquetted residues are charged. Gases are purified in a Cottrell apparatus and in a Thiessen. Their composition approaches blast furnace gas. About 18% are consumed for preheating, the rest is commercially utilized. Cottrell precipitates are dissolved for Zn electrolysis, the matte is sold to Pb refiners. JDG (2a)

Zinc in Germany (Deutsches Zink) H. Grothe. *Chemiker Zeitung,* Vol. 60, Mar. 25, 1936, pages 253-257. German Zn consumption, 200,000 tons annually, is second only to that of the United States, and is divided: 33.5% for rolled and pressed Zn, 26% for Zn alloys, 20% for galvanizing and 20.5% for the preparation of Zn oxide and other pigments. Zn is extracted by reduction of the oxide (distillation process) or by electrolytic deposition from a mineral acid solution of Zn salts. Both methods are described in some detail with flow sheets and discussion of process variations. FPP (2a)

Segregation Method for Lean Oxidized Copper Ores (Le procédé de ségrégation des minerais de cuivre oxydés pauvres) Maurice Rey. *Revue de Métallurgie,* Vol. 33, May 1936, pages 295-302. When Cu ores are reduced with C small particles of the metal remain imbedded in gangue. Addition of small amounts of chlorides before reduction collects metallic Cu on the surface of C particles. The chlorination process is about 10 times as fast as C reduction. Cl acts apparently in a closed cycle; only 1/10 of the amount required to form CuCl is required for extraction. Basicity of the gangue reduces efficiency of the process. NaCl can be replaced with $MgCl_2$, CuCl, $CuCl_2$ or $CaCl_2$; KCl and $BaCl_2$ give much inferior results. At the Alaska Mine of Southern Rhodesia Base Metal Corporation ore containing 5% Cu is roasted on the first 5 hearths of a furnace. About 0.4-0.5% salt and 1.5% coal finely ground are added on the sixth hearth. Segregation takes place on sixth and seventh hearths. The ore is then cooled in a rotary cooler. A months run in the furnace gave concentrate containing 68.2% Cu corresponding to 86.91% recovery. JDG (2a)

2b. Ferrous

Five Years of Progress in Southern Blast-furnace Practice. Francis H. Crockard. *American Institute Mining & Metallurgical Engineers Technical Publication* No. 653, Dec. 1935, 20 pages. Progress has been brought about by improved raw materials, modern furnace design, and careful attention to the Fe after it leaves the furnace. Coke ash has been reduced, resulting in lower cost of operation, closer Si control, and improved porosity. Pulverization of coal has yielded better coke structure. Sizing of both ore and coke has resulted in better operation and higher-quality product. Furnace design has tended to wider stock lines, resulting in less dust loss. Machine-cast Fe is triple skimmed and slowly cooled. Chemical analyses are better because of selected ores. Better practice has reduced coke consumption from 3000 to 2200 lb./ton of Fe in spite of burdens containing only 35% Fe and yielding over 2000 lb. slag/ton of Fe. JLG (2b)

Blast Furnace Improvements Needed. *Steel,* Vol. 98, Jan. 6, 1936, pages 245, 338-339. Reviews blast-furnace developments in 1935, as seen by several authorities. MS (2b)

Production and Preparation of Blast-furnace Flux. P. C. Hodges. *Metals Technology,* Jan. 1936, *American Institute Mining & Metallurgical Engineers Technical Publication* No. 668, 11 pages. Describes rock formation, quarry, and operation of Marble Cliff Quarry at Columbus, Ohio. JLG (2b)

Low-Temperature Reduction of Magnetite Ore. Effect of Catalytic Compounds. G. C. Williams & R. A. Ragatz. *Industrial & Engineering Chemistry,* Vol. 28, Jan. 1936, pages 130-133. Certain Na and K compounds greatly accelerate the rate of reduction of magnetite at 900° C. Hardwood charcoal is a much more active reducing agent than metallurgical coke and responds to the action of Na_2CO_3 as catalyst. The data tabulated in this article show that the catalytic effect of various compounds is a function of their concentration in the reducing mixture as judged by the action of alkali and alkaline earth carbonates. Silica tends to inhibit the action of Na_2CO_3. MEH (2b)

New Developments in Blast Furnace Practice. T. P. Colclough. *Iron & Coal Trades Review,* Vol. 132, May 1, 1936, pages 806-807. Using Northamptonshire ores the burden is designed so as to give the most economic conditions of operation within the furnace regardless of the S content of the pig Fe produced; any excess of S above specifications is removed by subsequent treatment after tapping the Fe from the blast furnace. The actual operation (covered by patent) is described. Ha (2b)

The Desulphurization of Pig Iron by Manganese (Die Entschwefelung des Roheisens durch Mangan) H. Wentrup. *Archiv für das Eisenhüttenwesen,* Vol. 9, May 1936, pages 535-542. The desulphurization of Fe by means of Mn and the effect of C alone and together with Si and P on the reaction was studied. At 1250° to 1350° C. the solubility of S in Fe is appreciably lowered by Mn. Desulphurization of pig Fe in ladle and mixer occurs by the floating up of the Fe S — Mn S complex to the slag. SE (2b)

Note on the Use of Scrap in the Blast Furnace (Beitrag zur Schrottverhüttung im Hochofen) W. Lennings. *Stahl und Eisen,* Vol. 56, Mar. 19, 1936, pages 349-351. Melting scrap in the blast furnace entails a high coke consumption. The heat generated by the coke is small, since it burns only to CO and not to CO_2. Data on coke consumption with varying amounts of scrap and different Fe ores are given. SE (2b)

High Alumina Blast Furnace Slags. A. D. Sokolskii. *Legkie Metallui,* Vol. 4, July, 1935, pages 18-40. In Russian. Slags containing 50-55% Al_2O_3, 40-45% CaO, and 3-4% SiO_2 can be obtained without difficulty in a blast furnace. HWR (2b)

Alumina from Blast Furnace Slags. P. B. Golubkov. *Legkie Metallui,* Vol. 4, July, 1935, pages 13-17. In Russian. Slags containing 50-55% Al_2O_3, 38-45% CaO, and 3.5-5.7% SiO_2 were treated with a solution of Na_2CO_3. At a temperature of 98°, about 80% of the Al_2O_3 was extracted in 5 hrs. The ratio SiO_2: Al_2O_3 in the solution was 0.004. HWR (2b)

Measurements on the Blast Furnace (Messungen am Hochofen) W. Liesegang. *Archiv für Technisches Messen,* Vol. 5, Jan. 1936, pages T5-T7. Measuring methods and instruments, and the correct places where the measurements are to be made are described for the blast heater, gases and waste gases, number and sequence of charge, blast temperature and composition of blast furnace gas. 19 references. Ha (2b)

Effect of Manner of Charging on Gas Currents in the Blast Furnace (Gasströmungen im Hochofen und ihre Beinflussung durch die Art der Begichtung) W. Feldmann & J. Stoecker. *Stahl und Eisen,* Vol. 55, Dec. 26, 1935, pages 1559-1564. Variations in gas flow in the upper part of the blast furnace with ordinary and interrupted charging, and with doubled and halved charge were determined. SE (2b)

Electrostatic Purification of Gases Produced in Smelting Ferromanganese. N. I. Korobov & N. G. Molchanov. *Metallurg,* Vol. 11, Apr. 1936, pages 34-48. In Russian. Experiments were conducted on a blast furnace having daily capacity of 90 tons, using 35% Mn ore and consuming 3 tons of coke/ton of metal. During operation 17% of the charge was carried away as dust. Detailed investigation of factors involved showed that purification to 0.2-1.5 g./m.³ can be effected in a single stage electrostatic precipitator provided the temperature of the incoming gas is kept between 70° and 90° C., its moisture content 100-130 g./m.³, speed 0.3-0.4 m./sec., time in the electrostatic field 6.5-10 sec. The tension of the latter should be between 35,000 and 44,000 volts with a current consumption of 10 to 30 amperes. For final cleaning moisture content and temperature have less influence. To produce gas containing 20-50 mg. dust/m.³ 30°-40° C. temperature, speed of 0.8-1.3 m./sec., time in the apparatus 2-4 sec., tension of 37,000-45,000 volts and 25-40 amperes current are satisfactory. (2b)

3. MELTING, REFINING AND CASTING

Metal Castings. H. L. Campbell. John Wiley & Sons, New York, 1936. Cloth, 6 x 9 inches, 318 pages. Price $3.00.

This is a text book, written for use at the Univ. of Michigan. In extremely concise form it describes the raw materials of the iron, steel and non-ferrous foundries, the melting and molding equipment, the fundamentals of melting and molding, the properties desired in molding and core sand, the properties and cost of the usual foundry alloys and deals briefly with die, permanent mold and centrifugal casting. Now and then the brevity of statement leads to the failure to mention alloys of importance, such as the Ford crankshaft alloy, but what errors there are, if they are to be classed as errors, are chiefly those of omission. Nobody will become a foundry expert just by reading the book because it does not go into real detail on any one topic, but for a well-balanced general presentation of the important fundamentals it is hard to beat. It is easy reading and would be as useful an introduction to foundry practice for home study as for a college course. Even the old and experienced foundryman might well get a copy to loan to younger men in the organization for many questions that the youngster would ask are answered more clearly and concisely by Campbell than in most other reference courses. H. W. Gillett (3) -B-

Molding and Founding (Formerei und Giesserei) A. Velten. Max Jänecke Verlag, Leipzig, 1936. Boards, 5¾ x 8¾ inches, 148 pages. Price 3.20 RM.

This book is an eleventh edition and bears all the earmarks of a good old book which has not been kept up to date. As a text book for engineering students it probably would convey some idea of the general principles of founding and of the technical complexities involved, but as a book for a man actually practicing in the foundry, it would be woefully deficient. It covers practically every conceivable operation in the foundry and necessarily must be very brief and sketchy in each item. Some serious changes of emphasis are apparent to the modern reviewer. More space is given to crucible melting in the gray iron foundry than is given to electric furnaces. No mention is made of alloy cast iron; nothing is said about refractories, either in furnace lining or ladle, or the chemical effect of acid or basic refractories; no mention of desulphurizing; nothing is said about rotary furnaces, either the powdered coal type or the electric furnace type. The old Roechling-Rodenhauser is the only electric induction furnace mentioned. Nothing is said of the effect of temperatures on cast iron and nothing about the health of the workmen and the important problems of dust removal. About the one modern thing the author seems to have over emphasized is the discussion of die-casting, which occupies 11 of the 17 pages devoted to the founding of non-ferrous metals. J. T. MacKenzie (3) -B-

You don't call a plumber to fix a clock!

And when that very personal machine, your body, gets out of kilter, you don't call a carpenter. You call a *specialist*—a doctor—a *good* one.

In a legal matter, you call a lawyer—a *good* one. And you should!

Do you apply this same common sense in handling foundry and cleaning room problems?

You should!

We are foundry specialists. We own and operate our own sources of materials, maintain our own laboratories and a staff of engineers trained in the selection and application of molding, core and blast sand, nozzles, core oil, refractories. These engineers serve our customers without charge. The price of our materials is no higher than that of materials sold to you without this supporting service.

It is as foundry *specialists* that we solicit your business.

Great Lakes Foundry Sand Co.

Foundry, Metallurgical and Sand Blast Engineering Service

United Artists Building **Detroit, Michigan**

Portland Cement as a Binder for Sand Molds and Cores. V. M. ANDREEV. *Metallurg,* Vol. 11, Apr. 1936, pages 60-69. In Russian. Cores and molds for cast Fe and bronze castings were made using: sand 78%, cement 15% and water 7%. Water turbine wheels were cast with very good results. The mixture is strong, porous and so plastic that no doctoring is required giving clean and accurate castings. A comprehensive laboratory investigation on different factors entering these mixtures is presented. (3)

Technical and Economical Points of View in the Manufacture of Aluminum Sand and Chill Mold Castings (Technische und wirtschaftliche Gesichtspunkte bei der Herstellung von Aluminium-sand- und Kokillenguss) A. v. ZEERLEDER. *Aluminium,* Vol. 18, May 1936, pages 203-208; *Aluminium & the Non-ferrous Review,* Vol. 1, May 1936, pages 365-370. The principles to be applied to economical construction with Al and light metal castings are discussed. The low elasticity modulus requires quite different sections from heavier metals. The influence of casting temperature and cooling is discussed and expressed in a table for different materials:

	av. tensile str. for		
alloy	sand castings kg./mm.^{2}	chill mold castings kg./mm.^{2}	percent of sand castings to chill mold castings
German alloy	15.5	18	86
American alloy	14.0	17.5	80
silumin	17.5	20.5	85
silumin β (not heat-treated)	18.5	24.0	77
silumin γ (heat-treated)	27	29	93
Y-alloy (not heat-treated)	17.5	23	76
Y-alloy (heat-treated)	25	27	93
alufont II	27	30	90
peraluman 7	18	25	72
anticorodal	25	28	29

Costs of castings, labor and overhead, are compared for silumin and cast Fe. Chill mold casting should be preferred to sand castings and are, under certain conditions, cheaper than grey Fe. 5 references. Ha + JCC (3)

Some Points in the Modern Production of Castings. A. PHILLIPS. *Foundry Trade Journal,* Vol. 54, Jan. 30, 1936, pages 102-107, 110. Paper presented to the Burnley section of the Institute of British Foundrymen. Molding and sand preparation, chemical and physical properties of molding sands, durability or ability with which sand can be used and re-used, oil sand cores, mechanized plant, alloy cast irons, drying, venting and pouring molds, cupola operation, etc. are discussed. The paper is illustrated with photomicrographs of different grade sands and with pictures of the mold conveyor of the pendulum type, of sand hoppers and special ramming facilities, push-plate conveyor supplying the hoppers, etc. AIK (3)

How Ford V-8 Crankshafts are Cast and Machined. W. F. PIOCH. *S. A. E. Journal,* Vol. 38, May 1936, pages 21-24. Description of procedure including details of core box preparation. No straightening operation is used, heat treatment is made before machining. Methods of balancing and finishing by polishing are reviewed. Cast shaft has double fatigue resistance of forged shaft and wear resistance is greater. WB (3)

Machine Moulding. D. R. KINNELL. *Foundry Trade Journal,* Vol. 54, Feb. 13, 1936, pages 137-140. Paper presented to the Middlesbrough Branch of the Institute of British Foundrymen. The author deals with machine molding and mentions some of the various examples of light-type castings which can be made successfully on small machines. The castings described weigh less than 40 lbs. each. Machine-made castings are more accurate and of better finish, owing to the fact that they are worked off a true plate pattern. Wastage of material such as sand, parting powder, etc., is cut down to a minimum as flasks and plate are made to suit each other. The plate pattern is more accurate when made from metal. The manufacture of the machine plate patterns is not an easy task. There are numerous possibilities to be looked into, the main item being accuracy. The making of machine-plate patterns, flasks, suitable type of molding machine, scope of the machine, organization of machine foundries, etc., are discussed. AIK (3)

Drying Molding Sands in Open Air (Séchage à l'Air libre des Sables de Moulage) GIRAULT. *Revue de Fonderie Moderne,* Vol. 30, Jan. 10, 1936, pages 4-6. Certain surface defects in Fe castings were traced to dirt carried along with the molten Fe, lack of cohesion of the sand in the patterns, and lack of sufficient permeability of the sand which causes boiling and oxides. These conditions and means to avoid them are discussed. Ha (3)

Beryllium Bronze Ingots. B. K. DERING & D. M. ZASLAVSKY. *Tzvetnuie Metallui,* May 1935, pages 94-102. In Russian. The technique of melting and casting Be bronzes developed by experimental work is described, and foreign practice is reviewed. Structure and properties of cast and worked metals are considered. BND (3a)

Pressure Die Castings in Brass. HERBERT CHASE. *Iron Age,* Vol. 137, May 7, 1936, pages 40-41, 103-105. Brass die castings can be made within closer dimensional limits as well as in thinner sections and in more complex forms than brass sand castings and forgings. Using metal at melting point rather than liquid metal increases the life of die. Some of the alloys used for die castings are Doler brass of about 1% Si; Brastil of 5% Si; a white Ni brass of 5% Ni and 12% Mn; and Mn bronze of 3.5% Mn maximum. Some of the general rules which apply to sand castings apply also in die castings. Shows some of the diverse types and sizes of die cast brass parts. VSP (3a)

Aluminum Refining (Aluminium-raffination) *Chemiker Zeitung,* Vol. 60, May 27, 1936, page 437. A new French process is described, based on the electrolysis of a molten mixture of 23% AlF_3, 17% NaF and 60% $BaCl_2$. Because the electrolyte melts below 750° C. the use of conventional refractory containers is possible and the difficulties attendant on water-cooling the walls in other processes are obviated. In one plant total current consumption is 10,000 amp., current density 40 amp./dm^2 at 7 volts. Current efficiency at the anode is 100% and at the cathode 97%. FPP (3a)

Magnefer is an infused dolomite refractory . . clinkered . . scientifically processed for maintaining the bottom and slag line of basic open hearth and basic electric steel furnaces.

Electrometallurgy Forges Ahead. Arthur Zentner. *Engineering & Mining Journal,* Vol. 137, Feb. 1936, pages 93-94. New developments in Al, Cu, Pb, Zn, and Cd are outstanding features of 1935. WHB (3a)

The Production and Control of Bronze Castings. Francis W. Rowe. *Metal Industry,* London, Vol. 47, Nov. 8, 1935, pages 459-463, 475. See *Metals & Alloys,* Vol. 7, June 1936, page MA 282R/6. HBG (3a)

Deoxidation and Degasification of Nickel Silver Alloys. R. J. Keeley. *Transactions American Foundrymen's Association,* Vol. 7, Feb. 1936, pages 251-255. The successful production of NiAg castings, while difficult, may be satisfactorily accomplished by proper attention to details. The following points may be helpful in the production of NiAg: (a) Pour at a sufficiently high temperature, the proper pouring temperature will vary with composition. (b) For sand castings containing more than 3% Pb, deoxidize with: 0.10% Mn (as 30% Mn-Cu), added a few minutes before drawing the crucible followed by 0.05% Mg (as stick Mg) just before pouring. (c) For sand castings containing below 3% Pb, deoxidize with up to 0.25% Si (as 10% Si-Cu). (d) Al should be excluded from all NiAg castings which must be pressure tight. Where pressure tightness is not involved and the sections are uniform the addition of 0.5% Al may be recommended for some purposes and in light sections such as typewriter parts, up to 3% has been successfully used. (e) The presence of either Si or Al requires more generous provision for feeding liquid metal to the castings. (f) The presence of Si, Mg or Al is objectionable in rolling mill alloys. CMS (3a)

The Basic-Bessemer Plant of Stewart & Lloyd in Corby, England (Das Thomas-Stahlwerk der Firma Stewarts & Lloyds in Corby) F. Lilge. *Stahl und Eisen,* Vol. 56, May 7, 1936, pages 537-544. A detailed description of the plant which has three 30-ton basic bessemer converters. SE (3b)

The Metallurgy of the Accompanying Elements in Steel (Zur Metallurgie der Eisenbegleiter) F. Körber. *Stahl und Eisen,* Vol. 56, Apr. 9, 1936, pages 433-444. It is shown that the formation of silicides, phosphides, and carbides in molten Fe influence the equilibrium between the melt and the oxides in the slag. The reducing effect of Si and C on oxides is lowered by the formation of compounds of these elements with Fe and Mn. Moreover the equilibria between the [Fe, Mn, Si] in the bath and the (FeO, MnO, SiO_2) in the slag are also affected by the presence of elements like Ni which do not form definite compounds with Fe and Mn. The reactions of Cr with MnO and SiO_2 of acid slags are depicted in a diagram, this indicating the Cr content of Mn silicate inclusions formed in the deoxidation of Cr bearing steels with Mn and Si. The behavior of V in acid and basic slags is illustrated. With acid slags V is more weakly reducing than Mn; the reverse is true with basic slags. When V is used in conjunction with Mn alone the deoxidizing effect of as little as 0.1% V is noticeable; when used with Mn and Si the deoxidizing effects of the latter overshadow the effect of V. SE (3b)

Melting Ferromanganese in a Tar-Oil Furnace (Das Schmelzen von Ferromangan im Teerölofen) J. Hoag. *Stahl und Eisen,* Vol. 56, Jan. 9, 1936, pages 40-47. The use of molten ferromanganese in steel-making makes possible a saving in Mn because greater accuracy in the desired steel analysis is obtained, than when solid FeMn is used. Molten FeMn is recommended, and tar-oil furnaces for this purpose are described and costs given. SE (3b)

Progress in the Gas Analysis of Steel and Ferro-Alloys by Vacuum Fusion (Fortschritte bei der Gasbestimmung in Stahl und Ferrolegierungen durch Vacuumschmelzung) R. Castro & A. Portevin. *Archiv für das Eisenhüttenwesen,* Vol. 9, May 1936, pages 555-562. An improved vacuum fusion train using a spiral C resistor furnace and the method of gas analysis are described in detail, various sources of error being pointed out. Very satisfactory results were obtained. SE (3b)

Studies of the Chemistry of the Acid Open-Hearth Process (Untersuchungen über die Chemie des sauren Siemens-Martin-Verfahrens) H. Schenck & E. O. Brüggemann. *Archiv für das Eisenhüttenwesen,* Vol. 9, May 1936, pages 543-553. With the aid of observations of acid open-hearth melts the equilibria of the Mn and Si reactions and the partition of FeO between bath and slag were redetermined and represented by equations and diagrams. The results were compared with those of Körber and Oelsen and other observers and some discrepancies indicated. SE (3b)

The Distribution of Sulphur Between Metal and Slag in the Basic and Acid Processes of Steel Manufacture. E. Maurer & W. Bischof. *Iron & Steel Institute,* Advance Copy No. 12, May 1936, 17 pages. Previous work on the behavior of S in steel-making processes is reviewed. Distribution of S was studied from numerous operating data from basic open-hearth process. These disclosed the powerful desulphurizing effect of Mn. The influence of SiO_2 content of slag was determined and shown as curves. The influences of MgO, Al_2O_3, and P_2O_5 in the slag and P in the metal were also considered. The behavior of S in the acid process is discussed in light of data secured from operating heats. These data reveal a dependence of S distribution on the P content of the metal. 22 references. JLG (3b)

Lecoeuvre. *Bulletin de l'Association Technique de Fonderie,* Vol. 10, Jan. 1936, pages 2-32. A very detailed account of casting method for steel locomotive cylinder, including preliminary study, intermediate steps, heat treatment, and time studies. Includes 72 sketches and tables. WHS (3b)

4. WORKING

4a. Rolling

RICHARD RIMBACH, SECTION EDITOR

Rolls for Rolling Mills. New Method of Making. Dynamic Solidification (Solidyna) (Les cylindres de laminoirs. Une technique nouvelle de fabrication. La solidification dynamique (Solidyna)) L. Quincy. *Revue de Métallurgie,* Vol. 33, Apr. 1936, pages 265-279. Rolls are cast in molds which are then closed and rotated around their axis until the metal solidifies. Centrifugal force eliminates influence of force of gravity so that the shrinkage cavity becomes centrally located and has a cylindrical shape. Grain size is refined, dendritic crystallization prevented and all non-metallic impurities are segregated on the surface of the internal cavity. The surface of the latter is free from oxidation. Speed of rotation at the start of solidification is equal to $n = 4548:VD$ and at the time of formation of shrinkage cavity $n = 1272:VD$ where n is number of revolutions and D the limiting diameter of the liquid layer in mm. For a roll with the diameter of the body of 400 mm. and of the neck of 240 mm. the respective speeds would be 290 and 127 r.p.m., but for practical uses 300-350 r.p.m. for cast Fe and 400-450 r.p.m. for steel are preferable. Major advantages of the process as compared with centrifugal casting of the usual type are: less destruction of the molds, possibility of handling heavy rolls, slow speed of rotation required in final stages of operation, freedom from shrinkage cavities which must occur in usual centrifugal casting of rolls and the lack of oxidation of the surface of consecutive layers of frozen metal. In the latter case solidification proceeds exclusively from the periphery towards the center. Longitudinal segregations are totally prevented, while radial segregations are practically of the same order of magnitude as in rolls cast in stationary molds. Internal cavity increases the elasticity of the rolls and facilitates their heat treatment. Largest roll cast by the new process measured 1200 mm. diameter and 3 m. length of the body. Rolls compare favorably with forged steel rolls and are more wear resistant than cast Fe rolls, particularly when they contain some Cr. JDG (4a)

Hot Strip in 3200-Lb. Coil Handled Over 450-Ft. Conveyor System. F. L. Prentiss. *Iron Age,* Vol. 137, Mar. 26, 1936, pages 58-61. Constant Speed Arrangement for Continuous Rolling Mills (Gleichlaufeinrichtung für kontinuierliche Walzwerke) H. Brauner. *Siemens-Zeitschrift,* Vol. 16, May 1936, pages 156-159. In continuous rolling mills where the material is in several rolls at the same time the speed of the rolls is adjusted automatically so that the material between 2 adjacent rolls is neither stretched nor looped. This is obtained by synchronous motors driven by the roll stands; these motors all have the same number of revolutions if the rolling stands have correct speed, and in case of deviation the slip currents act on the speed regulation of the roll motors. An installation is described. Ha (4a)

FIRTHITE TOOLS INCREASE OUTPUT

This FIRTHITE installation on a J. & L. Fay Automatic has increased production more than 50 per cent. It's just one of the jobs that demand FIRTHITE — a cast bronze bushing, 2½ in. diameter, turned, faced and chamfered, complete in 30 seconds.—In a previous operation the hole is finished with FIRTHITE tools. For this set-up, the bushing is held by an air-operated expanding mandrel, as may be seen. The machining cycle is fully automatic. The cut is taken at a speed of 700 ft. per minute.

Where output means everything, tool life is important because excessive down-time means excessive loss. With FIRTHITE tools, however, exceptionally long runs between grinds are assured. The cutting edge of a FIRTHITE tool resists wear because of its extreme hardness, producing piece after piece with a mirror-like finish without the necessity of tool adjustment.—It is for this reason, too, that exacting limits can be maintained on long runs. Interchangeability of bronze bushings is always an important factor but through the use of FIRTHITE the problem finds an easy solution.

A Firthite Engineer is available to give further details on many economies effected through the use of FIRTHITE TOOLS. Write us!

O. E. HARDER, SECTION EDITOR

The Heat Treatment of Cast Iron. A. A. Timmins. *Bulletin British Cast Iron Research Association,* Vol. 4, Apr. 1936, Bureau Report No. 148, pages 314-320. Reproduced from Staffordshire Iron & Steel Institute, Vol. 50, 1934-35. See *Metals & Alloys,* Vol. 7, June 1936, page MA 289L/1. WB (5)

Heat-Treatment of High Speed Tool Steels. Richard Saxton. *Sheet Metal Industries,* Vol. 9, Sept. 1935, pages 571-572. Insufficient soaking at hardening temperature is pointed out as a cause for failure though not generally recognized as such. Hardening and tempering operations are set forth. AWM (5)

■ 5a. Annealing ■

A Note on Stress Relieving Monel Metal. *Metals & Alloys,* Vol. 7, Jan. 1936, page 13. 600° C. (1112° F.) anneal for 3 hrs. of rolled Monel plate resulted in increase of proportional limit from 33,000 lbs./in.^{2} as received to 53,000 lbs./in.^{2} without marked effect on tensile strength or Brinell hardness. WLC (5a)

■ 5b. Hardening, Quenching & Drawing ■

Shallow Hardening, Factors Causing It. Francis B. Foley. *Metal Progress,* Vol. 29, Apr. 1936, pages 59-62. Discussion of split transformation on cooling, Ar′ and Ar″, between which austenite transforms directly to fine pearlite or troostite and below which to martensite. The time factor in transformation is influenced not only by temperature and alloy composition but by austenitic grain size and presence of crystalline nuclei whether from undissolved carbides or non-metallics. WLC (5b)

Quenched Steel—Why Is It Hard? Francis B. Foley. *Metal Progress,* Vol. 29, Mar. 1936, pages 52-56. General discussion of development of hardening theories. WLC (5b)

Electrical Treatment for Railway Lines. *Electrical Review,* Vol. 118, June 19, 1936, page 907. Brief description of American equipment for electrical heat treatment of rail ends already laid so as to minimize battering. Rail surface is first ground to correct inequalities. End is preheated by an induction device which places head of rail in the magnetic field of a transformer that is energized with high-frequency a.c. Temperature of rail is raised to proper degree for tempering by an apparatus which, using a train of gears and a cam system driven by a motor, causes an arc to move rapidly over the rail. Another device then applies oil to the head of the rail at a fixed temperature for an exact and controlled period of time. Hardness is thus raised from 260 to 400-450 Brinell. MS (5b)

Rails are Improved by Heat Treatment, by Controlled Cooling. *Metal Progress,* Vol. 30, July 1936, pages 41-45, 102. Cooling rails on special beds at the mill has been controlled to prevent the occurrence of transverse fissures. Heat treatment can be applied as rails cool from the mill by quenching in water at 60°-100° F. for 30 sec. when the edge of the base becomes magnetic, about 1200° F., with head surface 1360° F. and head center 1500° F. This cools the head to about 900° F. when the rails are transferred to a draw furnace maintained at 900° F. for equalizing and slow cooling. 900° F. is higher than the temperature at which the defects resulting in transverse fissures occur. End batter may be helped by local treatment with the oxy-acetylene torch, followed by quenching and drawing, or the rails may be end hardened at the mill. WLC (5b)

■ 5e. Carburizing ■

Heat Treatment Improves Sulphur Screw Stock. L. D. Spence & N. B. McLaren. *American Machinist,* Vol. 80, Feb. 12, 1935, pages 154-156. By correct carburization of high S steel, strength and toughness of the latter could be improved so that it could be machined at higher speeds. Figures are given for speeds after heat treatment at different temperatures. Ha (5e)

Case Hardening and Heat Treatment with Liquid Cyanides. E. G. Bishop. *Heat Treating & Forging,* Vol. 22, June 1936, pages 282-287. Paper read before the Steel Treatment Society of Australia. Discusses advantages and disadvantages of the cyanide method of hardening; dangers in use; operation, chemical reactions; maintenance of NaCN content of bath; effect of various factors on case produced; nitriding; use of accelerated cyanides; reheating carburized parts in cyanide baths; and selection and care of pots. Heat and Corrosion Resistant Alloys

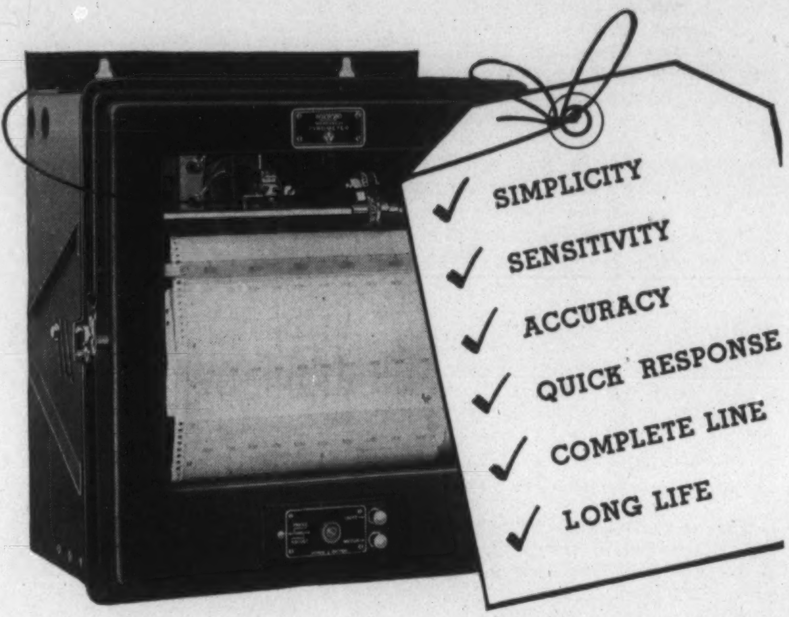
Let's check what you need in a

PYROMETER!



Let's check what Foxboro gives you. Foxboro gives you a dependable mechanism that is mechanically and electrically simple. You get instant response to thermocouple temperature changes. Every variation in temperature is quickly shown. You get a guaranteed accuracy of ¼ of 1% of scale range and a clear record on a 12-inch wide chart. Available is a comprehensive choice of models and ranges to meet precisely your specific requirements and above all you get all of these qualities year after year. Time does not impair the accuracy and responsiveness of Foxboro Potentiometer Recorders.

Give any Foxboro Pyrometer "the ear test." Listen carefully while it operates. It's almost noiseless. The Foxboro recording system operates at moderate speed and yet gives you speedy recording. Wear is reduced to minimum.

You'll find all the features, including the extra compensating slide-wire, described in detail in Bulletin 190-1. A copy is yours for the asking.

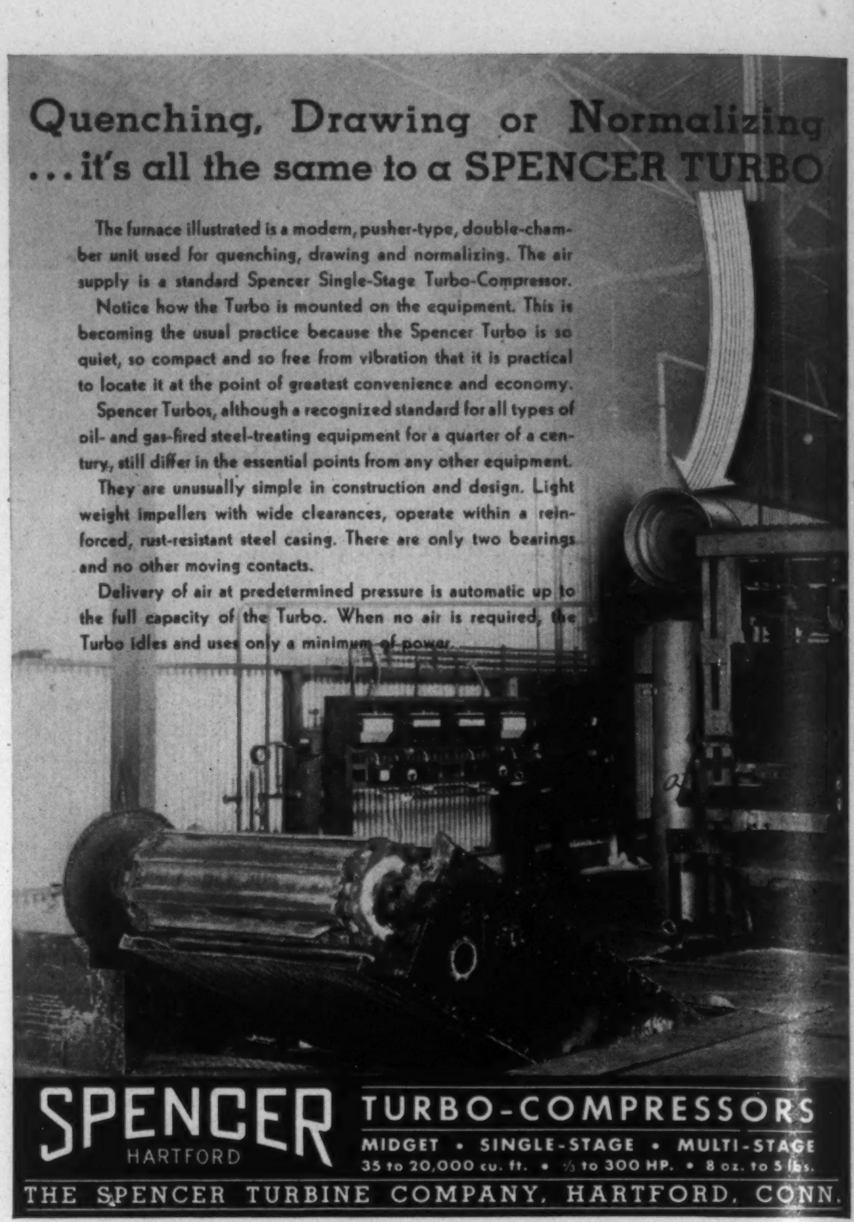
ACCURACY *RESPONSE*



Quenching, Drawing or Normalizing ... it's all the same to a SPENCER TURBO

The furnace illustrated is a modern, pusher-type, double-chamber unit used for quenching, drawing and normalizing. The air supply is a standard Spencer Single-Stage Turbo-Compressor.

Notice how the Turbo is mounted on the equipment. This is becoming the usual practice because the Spencer Turbo is so quiet, so compact and so free from vibration that it is practical to locate it at the point of greatest convenience and economy.

Spencer Turbos, although a recognized standard for all types of oil- and gas-fired steel-treating equipment for a quarter of a century, still differ in the essential points from any other equipment.

They are unusually simple in construction and design. Light weight impellers with wide clearances, operate within a reinforced, rust-resistant steel casing. There are only two bearings and no other moving contacts.

Delivery of air at predetermined pressure is automatic up to the full capacity of the Turbo. When no air is required, the Turbo idles and uses only a minimum of power.

6. FURNACES, REFRACTORIES AND FUELS

M. H. MAWHINNEY, SECTION EDITOR

Mounting of Furnace on Vibration Absorption Material Prolongs Refractory Life. R. C. Hess. *Industrial Heating,* Vol. 3, June 1936, pages 373-374. Attention is called to the damaging influence which vibrations of building or ground can have on the life of refractories in furnaces which may be destroyed by becoming loose before their useful life is ended by erosion. Placing channels in the floor with material of high damping properties on which the furnace rests is one of the most effective means of preventing vibrations from being transmitted to the furnace. Ha (6)

2

A New Galvanizing Furnace. W. H. Spowers. *Wire & Wire Products,* Vol. 11, June 1936, pages 286, 293, 300; *Industrial Heating,* Vol. 3, June 1936, pages 375-378; *Blast Furnace & Steel Plant,* Vol. 24, June 1936, pages 512-513, 538. **Galvanizing Kettle Heated Through Gas-fired Vertical Alloy Tubes in Walls.** *Steel,* Vol. 98, June 8, 1936, pages 56, 58. To prevent local overheating by a flame the direct impinging of the flame on the pot walls is prevented. Only glowing material either heated by flame or electrically is used for heating. Formation of dross was materially reduced. Constructive details are described. Ha + MS (6)

3

Insulation of Soaking Pits Improves Operation. S. M. Jenkins. *Steel,* Vol. 98, Mar. 9, 1936, pages 64, 67-68. Efficiency of soaking-pits can be greatly improved with little extra cost by constructing them of thin fire-brick walls insulated with high-temperature insulating brick and a sheet steel or concrete outer protecting wall. Steel or concrete casing prevents air infiltration. Presents results of tests on a recent installation, and on basis of these and additional tests on open-hearth regenerators tabulates insulation recommended for ideal soaking-pit. Soaking-pit covers also afford excellent opportunity for insulation. Insulation of recuperative type soaking-pits assures uniform heating, aids in low fuel consumption, and improves product. MS (6)

4

Industrial Liquefied Petroleum Gases. M. J. Conway. *Industrial Heating,* Vol. 3, June 1936, pages 363-366, 372-374. The advantages of saturated gaseous hydrocarbons, ethane, methane, propane and butane, as fuels are discussed and methods of producing and distributing them described. A table is given showing the rapidly growing use of propane and butane as fuels and their thermal properties. The same equipment as for natural gas can be employed. The price today is competitive with other fuels. Ha (6)

Refractories. *Times* [*London*] *Trade & Engineering,* Vol. 38, Jan. 1936, page XVIII. Reviews improvements made and research conducted during 1935. MS (6)

Heat Expansion Compensation on Invar Links (Wärmedehnungsausgleich an Invargliedern) W. Hiebsch. *Elektrowärme,* Vol. 6, June 1936, pages 190-192. As the temperature coefficient of invar increases with increasing temperature and is, at 500° C., about the same as that of other alloys arrangements are described to compensate for this changing thermal expansion by other suitable alloys in order to obtain accurate temperature control devices. Ha (6)

Refractories in the Foundry and Furnace. W. Hamilton. *Foundry Trade Journal,* Vol. 54, Jan. 30, 1936, page 101. Paper read before the Scottish Branch of the Institute of British Foundrymen. There is much in favor of using the Chammote type of material for certain molds, such as rolls or exceptionally heavy castings with a quantity of machined parts, as the free escape of gases through the material, after the mold has been filled with metal is very important factor. It improves the appearance of a casting generally, besides reducing machining allowance. Rapid strides have been made in the use of oil sands for cores and even molds during the last few years, so much so that in some foundries hundreds of tons of castings are made solely by this means. Sea sand, silica sand, and sometimes pit sand are the most favored, and extremely reliable bonding materials can be obtained from any of the various makers. For facing, there is now available a siliceous clay which, when used properly, can give good results both on sand and composition molds for steel castings. Linings for furnaces and refractory bricks are also discussed by the author. The cupola, which in the past was wholly lined with firebricks and patched with ganister or some proprietary material, gave quite good results; today the monolithic lining has appeared, and though its progress has been slow, the results obtained are making the average foundrymen consider the advisability of ramming up his cupola instead of relining with bricks. AIK (6)

Electric Furnaces for Case Hardening (Elektrische Oefen zum Einsatzhärten) G. Jabbusch. *Elektrowärme,* Vol. 6, June 1936, pages 177-184. Batch and continuous furnaces are described, operating data given. Ha (6)

Recent Improvements in Electric Furnaces with Crossed Channels (Les récents perfectionnements des fours électriques à canaux croisés) Jean Kuntziger. *Revue de Métallurgie,* Vol. 33, Apr. 1936, pages 244-246. Structural details of a resistance furnace using liquid resistor elements. JDG (6)

Heat Treating and Forging at the Ford Motor Company. W. C. Kernahan. *Heat Treating & Forging,* Vol. 22, June 1936, pages 273-281. Describes equipment and practice in plant at Dearborn, Mich., with much attention to the furnaces. Tabulates composition of the steels used. MS (6)

TAYLOR REFRACTORY INSULATING BRICK

Performance Report — **Subject:** Heat-treating, natural gas furnace, 39x39x39", with alloy steel muffle 13" high by 16" wide by 32" deep. Six inspirator type burners, with complete combustion in the SRM burner tunnel. Walls of 4½" Taylor Refractory Insulating Brick and 2½" Sil-O-Cel—total thickness of 7", with a 9" arch of Taylor Refractory Insulating Brick.

Furnace is used for heat-treating alloy tool steels preliminary to oil or water quench. Also used for carburizing.

Rate of Heating—Fuel Consumption—Processing— For processing alloy tool steel, furnace is lighted at 7:20 a.m. at a temperature of 325° F. Thirty minutes later it has reached 1550° F. with a fuel consumption of 332 cu. ft. per hour. Processing 251 pounds of alloy tool steel in three heats required 12 hours, at temperatures ranging from 1430° F. to 1825° F.

Heat No. 1—373 cu. ft.; heat No. 2—550 cu. ft.; heat No. 3—235 cu. ft.; making a total of 1158 cu. ft.

Carburizing at 1700° F., a 150-pound charge is placed in the furnace at 4:40 p.m. at 1000° F. At 6:00 p.m. temperature has reached 1700° F., and after five hours at this temperature, the charge is removed with a total gas consumption of 672 cu. ft. Depth of case is .05".

What this means to you!

Processing—Accepting the above figures as average production, with fuel costing 50 cents per 1000 cu. ft., 251 pounds of high-priced alloy tool steel is processed at a cost of $0.579 or $0.0023 per pound.

Carburizing—a charge of 150 pounds is carburized at a cost of $0.336 or $0.00224 per lb.

If you would have further information regarding the possibilities of Taylor Refractory Insulating Brick, write for the booklet—or consult our Engineering Department.

SOUTHPORT CONN.

Measurements with a New Color Pyrometer (Messerfahrungen mit einem neuen Farbpyrometer) K. GUTHMANN. *Stahl und Eisen,* Vol. 56, Apr. 23, 1936, pages 481-489. Measurements were made with the new combined color-brightness pyrometer "Bioptix," in the laboratory, blast-furnace, Bessemer, open-hearth, and foundry furnaces, and of forged and rolled parts. For molten steels readings within ± 10° C. of the true temperature were obtained, this being much more accurate than with the usual optical pyrometer. Measurements of flame temperatures were also obtained. SE (6)

Repairs to Electric Melting Furnaces. WALTER LISTER. *Metallurgia,* Vol. 14, May 1936, pages 21-23. Describes ways of building bottoms in arc furnaces. JLG (6)

Electric Furnaces to Bright Anneal High Carbon Steel. WILLARD ROTH. *Metal Progress,* Vol. 29, Jan. 1936, pages 35-38. Describes bell type equipment for annealing tool steel preparatory to cold working and in process. Overall costs on flat stock (razor blade steel) in coils is given as $7/ton for process anneal and $12/ton for the spheroidizing anneal. WLC (6)

The Open-hearth Furnace. Vol. I. W. C. BUELL, JR. Penton Publishing Company, Cleveland, 1936. Cloth, 6 x 9 inches, 276 pages. Price $4.00.

A series of articles by Buell, published in Steel since 1932 on "Improving Open-Hearth Design" is being brought up to date and rearranged into book form, to be published in 3 volumes. This one deals with the supporting steel work, refractories, design of hearth, walls and roof. Vol. 2 is to deal with the contour of the furnace in relation to efficiency, and Vol. 3, the regenerators and other external details. The data presented relate primarily to large basic furnaces rather than to steel foundry furnaces. They have been collected from many representative plants and give a useful picture of present practice.

Problems of heat flow through refractories and the value of insulation are given special prominence in this volume. H. W. Gillett (6) -B-

Ohio Heat Treating Company. W. C. KERNAHAN. *Heat Treating & Forging,* Vol. 22, May 1936, pages 219-222. Describes plant at Dayton, O. Equipment includes a large carburizing furnace, 3 furnaces for hardening alloy and high-C steels, 3 furnaces for hardening high-speed steels, 2 Pb-pot furnaces, 3 salt-bath furnace, a brazing furnace, a drawing oven, 2 cyanide furnaces, and 8 quench tanks. All furnaces are gas fired. MS (6)

Furnace Refractories. F. H. MORTON. *Chemical Trade Journal & Chemical Engineer,* Vol. 98, Apr. 3, 1936, page 285. Abstract of paper read before the Ceramic Society. Deals with development of insulating fire-brick. MS (6)

Electrically Heated Tubular Furnace with Heat Recuperation (Elektrisch beheizter Röhrenöfen mit Wärmerückgewinnung) K. MERTENS. *Elektrowärme,* Vol. 6, June 1936, pages 184-187. Advantages of utilizing the heat of the cooling end of the furnace and of the heated material for preheating the incoming material are explained and construction data for such furnaces and operating data are given. The energy consumption was as low as 120-150 kw.hr./ton of heated material. Ha (6)

Circular Furnace for Ingot Heating. M. H. MAWHINNEY. *Iron & Steel Engineer,* Vol. 13, Apr. 1936, page 6; June 1936, pages 26-29. Paper presented and discussed at A. I. & S. E. E. Engineering Conference, Youngstown, May 1936. Describes new circular ingot heating furnace with advantages claimed as follows, no cold corners, bottom firing, vigorous circulation and many small burners produces maximum temperature uniformity, control of atmosphere automatically through the fuel-air ratio reduces scaling and bottom maintenance. WLC (6)

Induction Heating. J. MARRYAT. *Electrical Review,* Vol. 118, May 29, 1936, page 773. Direct electric heating of metal parts by heavy currents at low voltages permits intense local heating at any desired point, and is highly efficient, economical, and rapid. Large-capacity transformer supplies ample current for particular purpose at 2.5-6 volts. Secondary winding usually consists of a single turn of heavy Cu, part to be heated forming a portion of this turn. Work is held in special H_2O-cooled Cu dies. Process is used for heating bars and pipes for bending; heating railway rolling-stock tires; annealing steel tapes and wires; and upsetting of valves, brake-operating cams, and other parts of automobiles. MS (6)

Annealing Sheet and Strip Steel with the Use of Electric Furnaces. A. N. OTIS. *Iron & Steel Engineer,* Vol. 13, Feb. 1936, pages 1-10. Paper presented and discussed at A. I. & S. E. E. Convention, Pittsburgh, Sept. 1935. Describes preliminary tests in batch and continuous furnaces tending to show that the product from batch furnaces is more uniformly annealed than that from continuous furnaces. These tests indicate an important factor to be watched in the development of continuous furnace design. WLC (6)

Measurements on the Rotary Furnace (Messungen am Drehofen) W. LIESEGANG. *Archiv für Technisches Messen,* Vol. 5, Feb. 1936, pages T19-T20. Measuring instruments and methods and the correct manner and place to carry out the measurement are described for temperatures, waste gases, and analyses of waste gases. 7 references. Ha (6)

High Frequency Furnace in Steel Plants (Le four à haute fréquence dans l'aciérie) D. F. CAMPBELL. *Revue de Métallurgie,* Vol. 33, Apr. 1936, pages 247-252. A brief survey of contemporary practice. JDG (6)

Electrical Furnaces of a New Type for Melting of Light Metals (Ueber neuartige Elektroöfen zum Schmelzen von Leichtmetall) H. DICKS. *Elektrowärme,* Vol. 6, June 1936, pages 162-171. Present developments are reviewed. Attention is called to the fatigue phenomenon of graphite crucibles which has the effect that, sometimes even after only 6-8 melts, the time for melting is doubled. The reduced heat conduction is ascribed to the combustion of the outer walls of the crucible. By melting brass and Cu in between, the crucible can, however, be recuperated. Metallic heating elements for an energy consumption of 6 watts/cm.² are now obtainable. A low frequency furnace for melting non-ferrous metals is described which uses 450-500 kw./ton of light metal. The life of the melting channel is, however, not as long as for heavy metals; frequent cleaning of the channel or groove from the adhering deposits and a densely tamped material for it are recommended. Operating and construction data of several types are given. Ha (6)

7a. Soldering & Brazing

C. H. CHATFIELD, SECTION EDITOR

Soldering and Solders (Löten und Lote) E. Lüder. A. W. F. No. 207, 2nd Edition. Beuth-Verlag, Berlin, 1936. Paper, 5½ x 8¼ inches, 66 pages. Price 1.75 RM.

Concise description of soldering, chiefly hand soldering, with some reference to mechanical soldering. German standards for SnPb solders ranging from 25 to 90% Sn are given. Data for strength of joints soldered with solder containing not over 0.5% Sb and with that containing Sb in amount of 6% of the Sn content are given showing the Sb-free to be generally the better for steel, poorer for Cu and about the same for brass. Brief mention is made of CdZn and of Cu brazing. Standards for brazing spelters and Ag solders and formulae for spelters with Sn or Si additions, for CuNiZn spelters and for AuAgCu solders for precious metals are given. Al solders are discussed with suitable warning as to danger of corrosion. In all cases the proper cleaning and fluxing practice is discussed.

From the point of view of conservation of Sn it is recommended not to cut the Sn content of soft solder too radically, since in the long run more Sn is used. The PbBiCd and other Sn-free Pb solders are not considered to make a generally satisfactory substitute, though usable in some cases. Electric welding is listed as a substitute method often available.

Suggestions are made as to solders for use on steel, cast and malleable Fe, Cu, and its alloys, Ni, and its alloys, and precious metals.

Soldering irons are illustrated with a recess for a Thermit cartridge which is ignited and heats the Fe to the proper temperature.

The pamphlet does not go into great detail on any topic, but is a useful introduction to the subject and cites the German standards so that from that point of view it is a useful reference book. It is not exhaustive enough nor does it give enough references to get the reader very far along any special line. For example, the paragraph on Cu brazing of steel says nothing about the proper order of clearance in the joint and the treatment of many other subjects is equally sketchy. H. W. Gillett (7a) -B-

Fluxes for Soldering—Suggestions for Metals and Alloys. *Chemical Engineering & Mining Review,* Vol. 28, Dec. 9, 1935, pages 51-52. Two general classes of fluxes are in common use: (1) includes substances of the type of tallow, resin, olive oil, etc., and (2) includes Zn-chloride, ammonium chloride, and HCl. Fluxes for general purposes are tabulated and fluxes for stainless steel, Al, and pewter are considered separately. WHB (7a)

* * *

Hard Soldering of Beer Conduits of Aluminum (Hartlöten von Bierleitungen aus Aluminium) K. Heinemann. *Aluminium,* Vol. 18, Mar. 1936, page 103. Instead of rather costly mechanical joints by screw and flange, hard soldering of Al pipes with Al rich solders (70-95% Al, with Cu, Ni, Ag, Mn, Zn, Sn, etc.) has given entire satisfaction both as to reliability and hygienic considerations. The soldered joint is made V-shaped. Ha (7a)

Broken Shaft of Large Rock Crusher Salvaged by Braze Welding. G. W. Irwin. *Iron Age,* Vol. 137, Apr. 2, 1936, pages 36-38. Describes the salvage of a broken rock rusher shaft by braze welding. The shaft was 14″ to 18″ in diameter, 12′ long and weighed 7 tons. Materials used for the job were 125 lb. of Airco 22 bronze, 4 lb. of Marvel flux, 500 ft.^{3} of acetylene, and 440 ft.^{3} of O. 7b. Welding & Cutting

E. V. DAVID, SECTION EDITOR

Welding—A Handy Tool. A. F. Davis. *Welding Journal,* N. Y., Vol. 15, May 1936, pages 19-23. A number of applications of arc welding are described and illustrated. WB (7b)

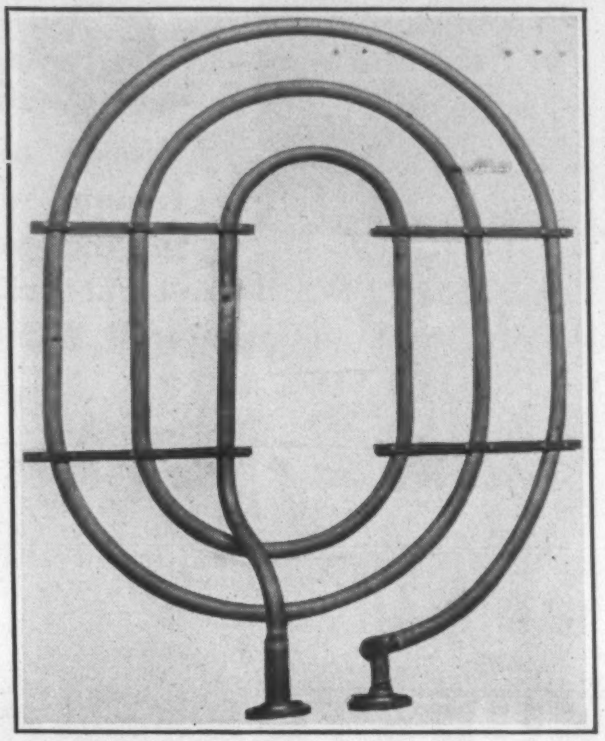
All-Welded Structural Steel Low-Height Flat Car. Charles Schenck. *Welding Journal,* N. Y., Vol. 15, June 1936, pages 2-5. Saving of 15% of weight of usual railroad car and lower height made possible by welding; details and photos shown. WB (7b)

Welding of Ni and Its Non-ferrous Alloys (La soudure du nickel et de ses alliages non-ferreux) A. Boutte. *Métaux,* Vol. 10, Dec. 1935, pages 341-346. General discussion on welding of Ni and its alloys. GTM (7b)

Illinois Cornfield Becomes Diesel Locomotive Works. *Iron Age,* Vol. 137, Apr. 16, 1936, pages 38-40, 53. Describes the Diesel locomotive works of the Electro-Motive Corp., division of General Motor Corp., at La Grange, Ill. Electrically welded structural steel throughout 9 buildings affords an unusual application of welding. 50,000 ft. of welding and 7½ tons of electrodes were used in erection of more than 2000 tons of structural members. Roof trusses and columns were welded by the Austin Co. and shipped to the site. VSP (7b)

Interesting Welding Job in

MONEL METAL TUBING



Your Welders can learn to do jobs like this... in an hour

● This "pancake" coil is one of three recently fabricated for use in heating fatty acids.

Despite the lightness of the material (.083″ wall), these coils must possess great strength to withstand the internal pressure, and extreme resistance to the corrosive action of the hot fatty acids. Hence, the tubing is cold-drawn Monel Metal.

The job of fabrication was simplicity itself...

Lengths of cold-drawn Monel Metal tubing, 1½″ dia. were gas welded together, after which the tubing was filled with sand and the assembly bent to template... all in the regulation way.

The flux used was Inco Welding and Brazing Flux dissolved in half-teacupful of very hot water to make a saturated solution.

The rod was Monel Gas Welding Rod #40, 3/32″ dia.

The torch-tip was about the same as that which would normally be used for steel...and the flame slightly reducing.

Working on Monel Metal tubing for the first time, welders will want to make a few welds on the scrap material and test for ductility, by crushing in a vise. Soon, operators should begin to make welds that will flatten without fracture of tube or weld.

The coils described above successfully withstood a water pressure of 100 lbs. p.s.i.

Our staff of specialists is at your service...entirely without obligation.

THE INTERNATIONAL NICKEL COMPANY, INC.
67 Wall Street, New York, N. Y.

MONEL METAL

Monel Metal is a registered trade-mark applied to an alloy containing approximately two-thirds Nickel and one-third copper. Monel Metal is mined, smelted, refined, rolled and marketed solely by International Nickel.

Application of electric welding to build up worn rails at crossings, repair of faulty riveted joints, boiler welding, bridge repair, and several crank shaft repairs are discussed. Use of coated rods is also discussed. CBJ (7b)

Residual Stresses in Arc-Welded Plates. N. S. Boulton & H. E. Lance-Martin. *Iron & Coal Trades Review*, Vol. 132, May 1, 1936, page 802. Continuous deposition of weld metal along one or both edges of a mild steel plate produced considerable longitudinal residual strains in the plate which were only to a small extent relieved by cutting the weld metal off. About 4/5 of the width of the plate welded along one edge (measured from the unwelded edge) remained practically elastic during and after welding. A study was made of the manner in which the heat penetrated into the plate and of the consequent stress distribution in the plate. A width of about ¾" from the welded edge was, after cooling, stressed in tension to the yield point (17 tons/in.^{2}), and all longitudinal elements within 1.4" of the welded edge were strained, at some time during welding, beyond the elastic limit. Ha (7b)

Sensitivity to Welding Cracks of High Tensile Steels (Schweissrissempfindlichkeit von Stählen höherer Zugfestigkeit) F. Bollenrath & H. Cornelius. *Stahl und Eisen*, Vol. 56, May 14, 1936, pages 565-571. By proper precautions in construction and welding internal stresses formed in welding can be lowered and cracking reduced to a minimum. Uniform heating and cooling is most important. Cracks can form after welding during cooling below 250° C. SE (7b)

Welded Underframes for Freight Cars. Scott D. Baumer. *Metal Progress*, Vol. 29, Mar. 1936, pages 41-43, 88. Describes development of welded gondola freight cars and methods followed in their production in a commercial car shop. WLC (7b)

Resistance Welds Widely Used. George H. Hall. *Electrical World*, Vol. 106, Jan. 18, 1936, pages 32-35, 78. Characteristics of butt, flash, spot projection and seam welding are discussed. Fields for successful application are pointed out. CBJ (7b)

Electric Welding and Its Applications. IX, X. M. Maurice Lebrun. *Welding Journal*, London, Vol. 33, Feb. 1936, pages 38-41; Mar. 1936, pages 70-73. Discusses welding machines and automatic welding. Part X cites rules for successful welding, compares bare and coated rods, and points out advantages and disadvantages of oxy-acetylene and arc welding. WB (7b)

Repair "in situ" of a 200 Ton Press (Reparation sur place d'une presse de 200 tonnes) R. Meslier. *Revue de la Soudure Autogéne*, Vol. 26, Jan. 1936, pages 5-7. Lecture before the Société des Ingénieurs Soudeurs. See *Metals & Alloys*, Vol. 7, May 1936, page MA 242L/1. FR (7b)

Autogenous Welding of Light Metals (Autogenschweissung von Leichtmetallen) M. Maier. *Autogene Metallbearbeitung*, Vol. 29, May 1, 1936, pages 129-134. Difficulties of soft and hard soldering of Al and its alloys are discussed and the advantages of autogenous welding discussed. A suitable flux is necessary in order to destroy the thin oxide film and to obtain a dense, pore-free weld. The acetylene flame must be so adjusted that there is a slight excess of O. The different procedures to be applied for different thicknesses and for castings are described in detail and illustrated by examples. Suitable solders and fluxes are given. Ha (7b)

Oscillograms Assist in Study of Welding Arcs. S. C. Osborne & W. F. Bailey. *Electric Journal*, Vol. 33, Feb. 1936, pages 87-89. Oscillographic study of welding circuit conditions improves the understanding of the electrical characteristics of the welding arc. Method of making the tests is described. CBJ (7b)

Gas Welding of Class 1 Pressure Vessels. G. W. Plinke. *Welding Journal*, N. Y., Vol 15, Apr. 1936, pages 20-24. Report of development of technique and procedure for gas welding with slightly reducing flame to bring ductility of weld in sections heavier than ½" up to standard ductility for Class 1 welds. Progressive hardness tests across double V weld shown in macro and max. for transition zone is 86.5 Rockwell B as against about 70 for parent metal. The impact and ductility values are up to requirements of Class 1 and X-ray shows sound welds. The author recommends the use of oxyacetylene flame in conjunction with arc welds in order to allow bare wire welds with protecting envelope of gas. WB (7b)

Welding as Applied to Heavy Machinery and Marine Engineering. H. N. Pemberton. *Welding Journal*, British, Vol. 33, Mar. 1936, pages 76-85. Review of paper and discussion at Welding Symposium 1935. WB (7b)

Aluminum Welding and Soldering in England and in Germany (Aluminium-Schweissen und -Löten in England und in Deutschland) L. Rostosky. *Aluminium*, Vol. 18, Apr. 1936, pages 143-145. The procedure and methods are compared. They agree to a great extent, but in England, pure Al is welded only with pure Al, while in Germany the welding wires have an addition of Ti. Ha (7b)

Experiments with Spot Welding of Aluminum Alloys (Versuche mit Punktschweissungen an Aluminiumlegierungen) K. Schraivogel. *Aluminium*, Vol. 18, May 1936, pages 177-183. Results from experiments prove that spot welding gives fully satisfactory joints with Al alloys with regard to strength and corrosion resistance. Procedure and equipment are described and suggestions for further development to secure consistently reliable values are made. 9 references. Ha (7b)

3,000,000 Sil-Fos brazed joints without a failure!

When a product meets every requirement in any particular kind of work, it is bound to win general acceptance.

SIL-FOS, the low temperature brazing alloy does just this in joining non-ferrous metals for many purposes. This fact is well demonstrated by its use on electrical equipment.

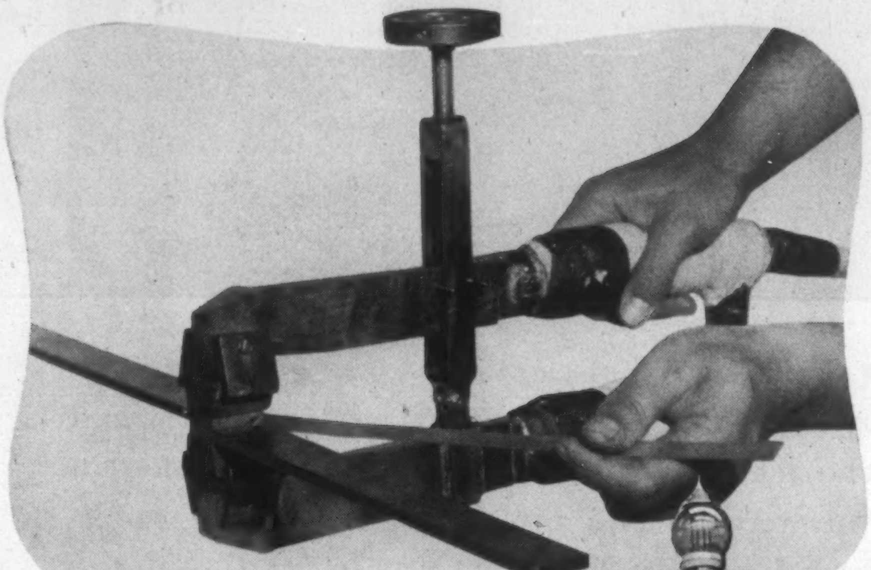
The General Electric Company use SIL-FOS in constructing their various sizes of transformers, large and small. They braze taps on coil conductors and join copper bars. On this work, SIL-FOS has made *over 3,000,000 joints without a failure.*

SIL-FOS gives this reliable service because the joints it makes at low temperature (1300° F). are strong and ductile—it actually alloys with the metals joined making them one solid piece highly resistant to severe shock, constant vibration and wide temperature changes. A joint which gives high conductivity—and due to the small amount of SIL-FOS required does the job at low cost.

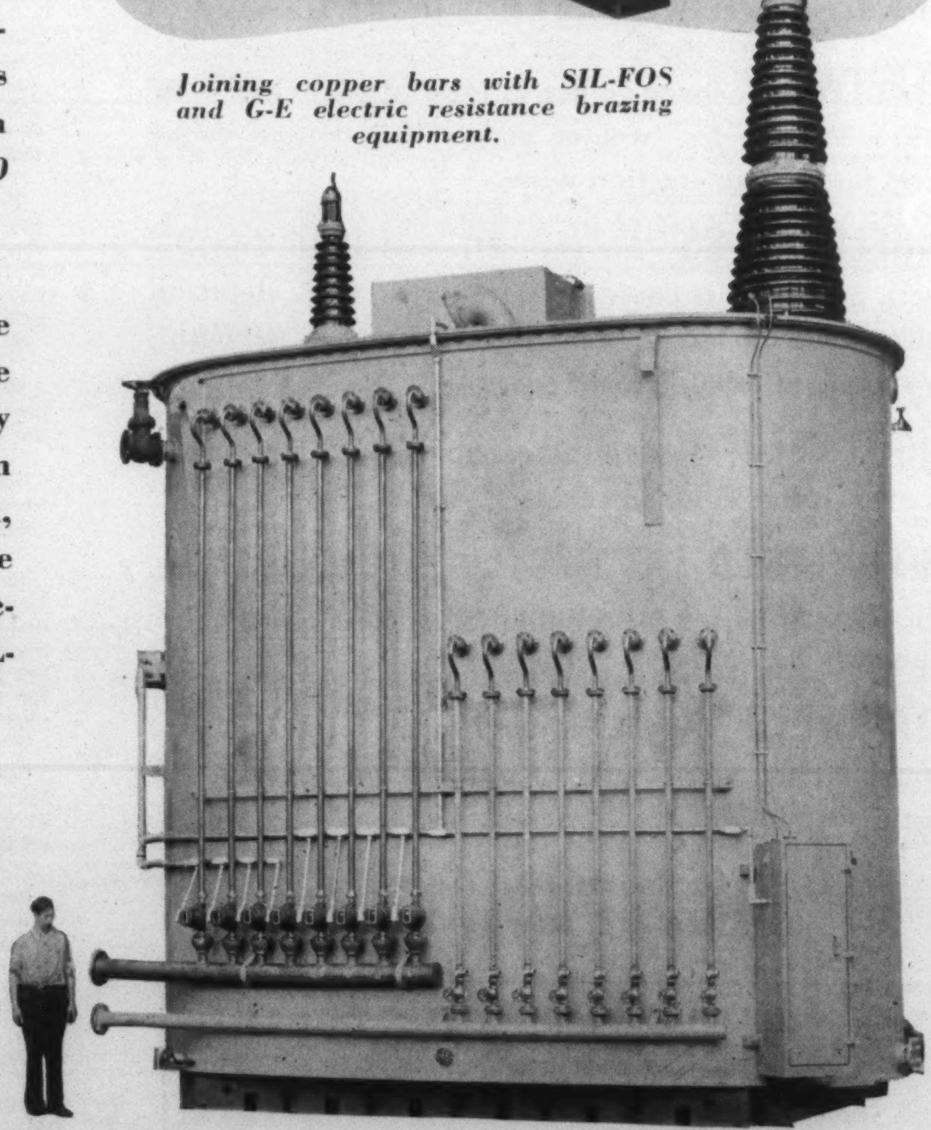
●

Try SIL-FOS on your work.

Use it with our low temperature HANDY-FLUX. Write us for Bulletin 59 MA and our recommendations.

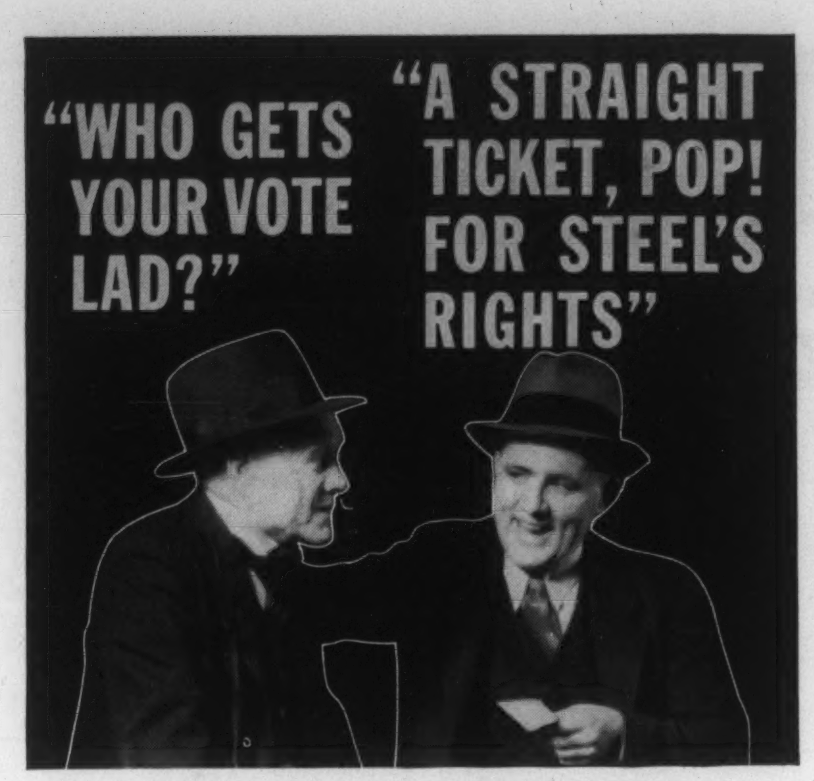


Joining copper bars with SIL-FOS and G-E electric resistance brazing equipment.



SIL-FOS was used in making this G-E 55,000 KVA Power Transformer for U. S. Bureau of Reclamation, Boulder City, Nevada.

HANDY AND HARMAN 82 Fulton St., New York



"WHO GETS YOUR VOTE LAD?"
"A STRAIGHT TICKET, POP! FOR STEEL'S RIGHTS"

● "Here's a list of candidates who get their votes by kissing the top-marks on test machines and who acknowledge your X by putting a feather in your topper. The 'top' in service-proved candidates for Lower Welding Costs in Steel"—

"FLEETWELD" for the office of Mild Steel. When used with a *"Shield-Arc"* welder makes that molten metal travel faster than election news.

"SHIELD-ARC 85" for the office of High Tensile Steels. So strong it could support the G. O. P. elephant with a weld no larger than a pencil (tensile strengths are around 100,000 lbs. per sq. in.).

"LIGHTWELD" for Light-gauge Steels. Produces smooth, strong welds in sheets of ballot-thinness.

"CHROMEWELD 4-6" for 4-6 Chrome Steel. Produces weld structures more homogeneous than a booming home-state delegation.

"STAINWELD" for Chromium-Nickel Steels. Columbium-bearing, welds will withstand many terms of caustic treatment.

Vote here for better welds at lower cost

Present Status of Structural Welding. W. M. WILSON. *Journal Western Society of Engineers,* Vol. 41, Feb. 1936, pages 8-18. A survey purporting to show the extent to which structural welding has been adopted, the reasons, its limitations and the developments whereby its use may be extended and made more satisfactory. Advantages of welding over riveting are: (1) economy, (2) adaptability and (3) flexibility of design. The most serious difficulties encountered in structural welding are: (1) distortions due to welding, (2) thermal stresses, and (3) the low strength of welds subjected to dynamic, repeated, and reversed loads. A machine for fatigue testing of moment-resisting welded joints is described and tests tabulated. WHB (7b)

Prediction of Weld Performance. NAIRNE F. WARD. *Welding Journal,* British, Vol. 33, Jan. 1936, pages 14, 18. See *Metals & Alloys,* Vol. 7, May 1936, page MA 240R/3. WB (7b)

Some Effects of Generator Characteristics on Welding Costs. JOHN H. BLANKENBUEHLER. *Welding Journal,* N. Y., Vol. 14, Sept. 1935, pages 36-38; *Iron Age,* Vol. 137, Jan. 23, 1936, pages 20-22. Discussion of static and transient characteristics of welding machines. Table shows various types of coated and bare electrodes compared as to excellence factors, deposit efficiency, etc., and relative costs are given in terms of lbs. deposited per unit time, unit power, unit weight of electrode purchased. WB + VSP (7b)

Fundamentals of Spot Welding with Particular Reference to Electrode Life. E. I. LARSEN. *Welding Journal,* N. Y., Vol. 15, Apr. 1936, pages 25-31. The important factors in spot welding electrode life are electrical and thermal conductivity, tensile properties and hardness at slightly elevated temperatures, design of electrode, method of cooling of electrode tip, welding pressure and material of which electrode is made. 3 materials were investigated:

Material	Elastic limit lbs./in.^{2}	Ultimate strength lbs./in.^{2}	Rockwell B	% conductivity Cu 100%	Annealing temp. ° F.
Copper (hard)	7,000	35,000	50	98	370
Elkaloy A	45,000	65,000	70	80	660
Mallory 3	50,000	70,000	80	80	1000

The last is shown to be important due to decrease in tip pressure when material flows during use and area of tip is increased thereby. Results of spot tests for the 3 materials are shown for % increase in tip area per thousand spots in welding cold rolled steel, terne plate, stainless steel. The decrease in pressure due to increase of tip area is shown in curves. In all the tests Mallory 3 appears to have longer life than the other metals which is shown by life tests in no. of spots/in. of electrode.

	Copper	Elkaloy A	Mallory 3
No. of spots	489	1362	4590
Material cut away in dressing	.041"	.036"	.024"
Spots/in. of electrode	11,927	37,833	191,250

Some spot welds are discussed which were made under conditions of insufficient heat, proper heat and excessive heat, the micros are shown of the spot. Effect of mushrooming of electrode tip and decreased pressure is shown to be poor bond with no grain growth across the boundary. WB (7b)

Field of Arc Welding Expands. GEORGE H. HALL. *Electrical World,* Vol. 106, Feb. 1, 1936, pages 32-35. Applications of arc welding are usually in construction repair and field work rather than factory production processes. Fabrication of tanks, boiler shells and similar products is done by automatic arc welders. Numerous types of industrial applications of arc welding are discussed. Available methods for arc welding and significant features of different welders are discussed. CBJ (7b)

Tabular data presented for carbon arc, oxyacetylene, metallic arc and stitch welding. WB (7b)

8. FINISHING

H. S. RAWDON, SECTION EDITOR

Inferior Base Material as the Cause of Defective Coatings of Zinc and Enamel on Steel Sheet (Mangelhafter Kernwerkstoff als Ursache fehlerhafter Überzüge auf verzinkten und emaillierten Stahlblechen) HANS FROMM. *Forschungsarbeiten über Metallkunde und Röntgenmetallographie,* No. 11, 1934, pages 10-24. Discusses conditions of steel sheet that cause defects in enamel, Zn, Sn, and Pb coatings. Steel sheet to be pickled and coated should be selected in accordance with the following requirements: Only killed steel should be used. Owing to tendency to segregate, the sum of P and S should not exceed 0.06%. Steel that will coat properly should be selected by the maker rather than by the buyer on the basis of analysis. The ingots should be rolled at a temperature high enough to weld sub-surface blowholes. For ingots with pronounced top segregation or deep pipe, the top discard should be at least ⅓ of the ingot weight. The final pass in rolling should give a reduction of 5 to 8% and the sheet should be as cold as possible for this pass. During rolling, scale should be removed by water at high pressure. The surface of the sheet should be scaled as little as possible and local heating should be avoided. If the annealing temperature in box annealing is not high, critical reduction in rolling should be avoided. The C should not be under 0.05% and all carbide should occur as pearlite, not as grain-boundary cementite. JLG (8)

8a. Pickling

Notes on the Efficient Pickling of Iron and Steel. C. H. MCCOLLAM & D. L. WARRICK. *Metal Progress,* Vol. 29, May 1936, pages 61-67. Notes on acid used and inhibitors and technique recommended for economical pickling in 1936 edition, National Metals Handbook. WLC (8a)

8b. Cleaning including Sand Blasting

Cleaning Billet Surfaces with Oxy-Acetylene Flame. ERNEST E. THUM. *Metal Progress,* Vol. 29, May 1936, pages 35-38. Billet cleaning for seamless tubing production was investigated by dividing 75 ton heat into 3 equal parts; chipping gave a loss of 500 lb. of metal and cost \$2.50/ton; using a planer or gouging machine gave a metal loss of 1500 lb. and cost \$1.25/ton; and with acetylene flame metal loss was 900 lb. and cost \$1.00/ton. Billets are first pickled in concrete tanks lined with paving bricks set in molten S. 200 tons of billets may be pickled in 2 hrs. at a cost of \$0.15-0.20/ton. Torch used and technique of defect removal with it are described. WLC (8b)

8c. Polishing & Grinding

The Polishing of Metals. E. J. DOBBS. *Aluminium & Non-Ferrous Review,* Vol. 1, Mar. 1936, pages 184-186. Paper before the Midland Metallurgical Societies, with discussion. Polishing operations before and after electro-plating are described. Solid felt "bobs" dressed with emery of different grades are generally used first and are followed by polishing "mops" dressed with tripoli, rouge, alumina, lime, crocus, or chromium oxide for the final operation of "colouring" before plating. Similar mops are also used for "finishing" after plating. JCC (8c)

Ribbon-, Disc- and Drum-grinding Machines in the Metal Industry (Band-, Teller- und Trommelschleifmaschinen in der Metallindustrie) F. FACHTNER. *Oberflächentechnik,* Vol. 13, May 5, 1936, pages 103-104. Various types of grinding machines are described and their field of application according to purpose and material defined. Average velocities of grinding are for Pb 12-15 m./sec., cast Fe 28 m./sec., Al alloys lower or higher than 28 m./sec. Details of construction are given. Ha (8c)

Barrel Burnishing. WALTER R. MEYER. *Aluminium & the Non-Ferrous Review,* Vol. 1, Apr. 1936, pages 318-319. Abbreviated translation from *Oberflächentechnik.* See *Metals & Alloys,* Vol. 7, June 1936, page MA 302R/6. JCC (8c)

Abrasives Used in the Polishing and Buffing of Metals. A Correlated Abstract. I, II, III. R. S. LEATHER. *Platers' Guide,* Vol. 32, Apr. 1936, pages 15-17; May 1936, pages 24-25, 28; June 1936, pages 16-18. Digest of recent literature on the subject. Differences between polishing and buffing abrasives are outlined. The abrasive action on metals is discussed and a comparison made between fused Al_2O_3 and Turkish emery. The use of silicate of soda as a binder for holding the abrasive to the set-up wheels is increasing. A single coat of abrasive is more economical than a double coat. The value of emery depends upon the amount of crystalline Al_2O_3 contained. The efficiency of a polishing medium as expressed by the metal removed is compared with abrasive material. Capillarity test, exact sizing and uniform shape of grains, artificial vs. natural abrasives, treated grain and physical properties of the abrasive on which depends ability to cut a metal surface are considered. WHB (8c)

Finishing of Manganese Steel Parts by Grinding. FRED B. JACOBS. *Iron Age,* Vol. 137, Mar. 12, 1936, pages 46-50. Describes procedure of Marion Steam Shovel Co., where steam shovel parts are made of Mn steel because it resists abrasive action and at the same time possesses high tensile strength. VSP (8c)

8d. Electroplating

Concentrated Copper Cyanide Baths. L. C. PAN. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 47, Nov. 8, 1935, pages 471-474. See *Metals & Alloys,* Vol. 6, Nov. 1935, page MA 454L/10. HBG (8d)

Nickel Plating and Chromium Plating of Aluminum and Aluminum Alloys (Die Vernicklung und Verchromung von Aluminium und Aluminiumlegierungen) E. RAUB. *Mitteilungen des Forschungsinstituts und Probieramts für Edelmetalle,* Vol. 9, Feb.-Mar. 1936, pages 111-121. Plating of Al or its alloys with Ni or Cr is possible only after the natural oxide film has been thoroughly removed. The various methods developed with more or less success during the last 30 years are reviewed and the methods most widely used discussed. The most successful are the method of Ballay, with Fe chloride, and that of Altmannsberger, with zincate. Fischer (DRP 606,850 and 611,643) oxidizes the Al at first electrolytically and treats it afterwards cathodically in a degreasing bath containing heavy metals, e.g. Cu and Zn, whereby a thin film of the heavy metal is deposited on Al which makes it respond to treatment in the usual plating baths. A pore-free, dense deposit is obtained only on a pore-free, dense basis. The porosity of Ni deposits and corrosive attack were investigated under different conditions and the adhesion and ductility of the deposits determined. The greater the initial surface roughening before plating, the better was the adhesion and resistance against corrosion of the coating. A pore-free, corrosion-resistant coating of Ni on Al must have a thickness of at least 0.02-0.03 mm., which is about the same as for Fe. After being highly polished the Ni deposit can still be Cr plated which gives an excellent corrosion resistance even on material which is bent 90° and 180°. Ha (8d)

Pictorial Study of Plating Conditions. W. M. PHILLIPS. *Monthly Review, American Electroplaters' Society,* Apr. 1935, pages 21-31. A small glass electrolytic cell is placed in a projector and the effects of the current in passing from anode to cathode through the solution can be projected on the screen. Dissolving of the anode, color changes in the solution, pitting of the deposit, and other effects are studied visually. GBH (8d)

Contribution to the Study of Nickel Plating Duralumin (Contribution à l'Étude du Nickelage du Duralumin) E. DECARRIERE & A. HACHE. *Chimie et Industrie,* Vol. 33, May. 1935, pages 595-596. Conclusion of a series of researches in which the author has studied the action of cementation, electrolysis, and use of Sb as an auxiliary metal to obtain a Ni plate. MAB (8d)

Glossy, Gray and Black Chromium Plating (Glanzchrom-, Grauchrom- Schwarzchrom) A. WEISS. *Oberflächentechnik,* Vol. 13, May 5, 1936, pages 101-102. Glossy, bright Cr deposits can be obtained only within a certain range of current density which depends on the cathode material and particularly on the temperature. For previously Ni plated parts, this lies between 5 and 15 amp./dm.^{2}, for 40° C. and between 12 and 30 amp./dm.^{2}, for 50° C. Above this, gray (burnt) deposits are obtained. Very high current densities produce very hard, gray layers which contain about 1000 times their volume of H. No Cr oxides are found. Black deposits are obtained with 100-150 amp./dm.^{2} density. Very deep black deposits are produced if acetic acid or any other organic acid is used instead of H_2SO_4. The voltage for the bath must be 11-14 volts as the currents are about 10 times as high as in bright Cr plating. The strong H evolution requires an exhaustor and the temperature must be kept below 15° C. Direct black Cr plating is not to be recommended as it takes too long a time and is therefore costly. It is best to Ni plate first, then bright Cr plate and finally black Cr plate for a very short time, about 1 min. Black Cr plating is advantageously applied where formerly black Ni plating or black lacquer was employed; although more costly black Cr deposits have a higher mechanical and chemical resistance. DRP application 110226 covers a "bright-gray-black Cr plating process." 11 references. Ha (8d)

Electrogalvanizing of Round Wire. A. WEISSELBERG. *Wire & Wire Products,* Vol. 11, June 1936, pages 281-285, 290. Existing processes for electro galvanizing are reviewed and critically compared with hot galvanizing. Operating advantages are (1) maximum Zn economy as there are no Zn losses, (2) no losses during shut-downs, (3) accurate control of the thickness of the coating, and (4) clean and sanitary condition of the plant. The coating is very uniform and a thickness of 0.2 oz./ft.^{2} can be obtained in one run. Physical properties of the wire are not affected by the electrolytic process as they are in hot galvanizing, particularly for C spring steels. The coating of pure Zn is highly ductile and adheres perfectly, is smooth and easily shows up defects of the wire. The cost/ton galvanized wire is given as \$9.70 for 0.6 oz./ft.^{2} coating and \$13.15 for 1 oz./ft.^{2} Ha (8d)

Electrolytic Deposition of Bivalent Europium (Die elektrolytische Abscheidung des zweiwertigen Europiums) A. BRUKL. *Angewandte Chemie,* Vol. 49, Feb. 29, 1936, pages 159-161. Difficulties in depositing the rare-earth metals are briefly explained and a method described which permits an easy separation of Eu from accompanying elements on Hg cathodes. An addition of isomorphous Sr sulphate makes possible the deposition from solutions with even less than 2% Eu_2O_3. Ha (8d)

Electrolytic Plating of Aluminum in Fused Salt Solutions. S. I. ORLOVA & V. I. LAINER. *Legkie Metallui,* Vol. 4, Dec. 1935, pages 9-16. In Russian. Best results are obtained by using a chloride solution with a molecular ratio of $AlCl_3$: NaCl of 2:1 and a current density of 0.2 to 0.5 amp./dm.^{2} at a temperature of 120° C. The $AlCl_3$ in the electrolyte is volatile and inferior results are obtained as its concentration decreases. The addition of 0.2% $PbCl_2$ to the electrolyte improves the coating. HWR (8d)

The Electrolytic Deposition of Alloys (Deposits electroliticos de aleaciones) J. IBARZ. *Metalurgia y Construccion Mecanica,* Vol. 2, June 1936, page 2. Discusses the electrochemical processes which make possible the electrodeposition of metals or alloys. FRM (8d)

Durability of Plated Steel Exposed to Weather. WILLIAM BLUM. *Metal Progress,* Vol. 29, Feb. 1936, pages 40-41. Results of exposure tests and several methods of measuring coating thickness are briefly described. Results of these tests by the Bureau of Standards in coöperation with A.S.T.M. and American Electroplaters' Society have established certain essential requirements. For Zn and Cd: (a) general service, minimum thickness 0.0005", (b) mild service, minimum thickness 0.00075". For Ni and Cr (a) general service, minimum thickness of Cu + Ni 0.00075" with at least 0.0004" Ni and average Cr thickness of 0.00002", if required, plate to withstand 48 hrs. continuous salt spray, (b) mild service, minimum Cu + Ni 0.0004", at least ½ of which is Ni, and Cr, where required, 0.00002", plate to withstand 16 hrs. salt spray test. WLC (8d)

A Study of Al-Hg-Zn Anodes in Acid Zinc Plating Baths. A. K. GRAHAM & P. G. KOLUPAEV. *Metals & Alloys,* Vol. 7, Jan. 1936, pages 14-17. Best bath consists of $ZnSO_4.7H_2O$ 32 oz./gal., $Al_2(SO_4)_3.18H_2O$ 4 oz./gal., NH_4Cl 2 oz./gal., pH 4. Operation at 32-42° C. (90-108° F.) with anode current density 20-100 amp./ft.^{2} and cathode current density below 45 amp./ft.^{2} results in anode efficiency of 99%, polarization under 0.2 volt, bath free from sludge, and a satisfactory adherent deposit. With bath voltage about 2.0 volts and current density of 45 amp./ft.^{2} the change in pH is negligible. Plain Zn anodes result in sludging of the bath. WLC (8d)

The Role of Films in the Electrodeposition of Metals. A Correlated Abstract. WALTER R. MEYER. *Metals & Alloys,* Vol. 7, May 1936, pages 123-126; June 1936, pages 155-159. Classifies films as (1) preferential-solution films consisting of a smudge of undissolved material as C or carbides on pickled steel or Fe left by the cleaning solution, (2) deposited films of dirt, grease or smuts and absorbed colloid, (3) passive films and (4) polishing films. These various films are discussed as to manner of formation, effects upon adherence of deposit and remedies applied to different materials. Influence of basis metal structure on that of deposit is discussed. The role of films formed intentionally on plated deposits or unplated metals for effecting surface protection is discussed. 153 references. WLC (8d)

Improvement in the Quality of Tinplate by Superimposed Electrodeposition of Tin. A. W. HOTHERSALL & W. N. BRADSHAW. *Sheet Metal Industries,* Vol. 10, Jan. 1936, pages 15-18; Feb. 1936, pages 139-140. **Closure of Pores in Tinplate by Electrodeposition.** *Metal Progress,* Vol. 29, Jan. 1936, page 39. Iron in the Chromium Bath and Its Precipitation (Das Eisen im Chrombade und seine Ausfällung) E. RAUB. *Mitteilungen der Forschungsinstituts und Probieramts für Edelmetalle,* Vol. 10, Apr. 1936, pages 1-7. The harmful presence of Fe in Cr plating baths, its origin and chemical reactions are explained, and means for removing it by electrolytic precipitation were investigated. The harmful effect becomes noticeable at 5% Fe in the bath (referred to chromic acid) and increases with increasing Fe content, with 10% Fe, however, Cr-plating is still possible. From baths very rich in Fe (dull gray) Cr deposits contaminated with Fe are produced. The precipitation of the Fe is feasible but is a very tedious process which is profitable only for large volumes of bath solutions. It is more advisable to prevent accumulation of Fe by proper working conditions and supervision. This can be done as the sources of contamination of the Cr bath are known and, therefore, can be prevented. Ha (8d)

The Electrodeposition of Bronze Using Bronze Anodes. S. BAIER & D. J. MACNAUGHTAN. *Technical Publications of the International Tin Research & Development Council,* Series A, No. 27, 1936, 14 pages; *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 47, Nov. 29, 1935, pages 543-546; Dec. 6, 1935, pages 567-570. Paper read before the Electrodepositors' Technical Society at Northampton Polytechnic Inst., Clerkenwell, London, Oct. 30, 1935. The paper describes some of the results obtained as a part of a series of investigations planned by the International Tin Research & Development Council. In preliminary work it was found that Ni or Cu, added to a stannate solution as complex cyanides, could be co-deposited with Sn. Extension of the work (by Bechard) to the deposition of Cu-rich Sn-Cu alloys (bronzes) from baths rich in Cu established the superiority of this type of bath over the oxalate bath used in earlier investigations. In this paper are reported the results obtained with a bath of this type. The anodes were cast bronze rods containing 12% Sn, annealed 1 hr. at 700° C. The solution used had the following composition;

commercial copper cyanide	150 g./liter,
" sodium stannate	50 g./liter,
sodium cyanide	15 g./liter.

The solution was kept at 65° C. during deposition. Data for anode and cathode efficiency are reported graphically, the method of obtaining these data described, and the method of balancing these efficiencies indicated. The hot water porosity tests used are described and data obtained on throwing power of the solution are given. It is suggested that the excellent throwing power of the bronze solution may be explained by the pronounced fall of cathode efficiency with increase in current density. Comparative tests were made of Cr plating of steel specimens previously coated with bronze and Ni. When tested for porosity in hot water the Cr plate on bronze was equal to, and in some instances superior to, the plating on Ni. It is stated that the Brinell hardness of electrodeposited bronze is harder than annealed bronze and comparable to that of hard Ni deposits. The method of analysis of electrodeposits of bronze on steel is indicated. The article is illustrated. 16 references. HBG (8d)

Electrodeposition in Dentistry—Application to Inlay Dies. J. A. VIVERITO & JOHN DAMIANO. *Dental Cosmos,* Vol. 22, Nov. 1935, pages 1202-1210. Detailed directions are given for producing Cu shell dies for inlays. The surface of the wax model is made conducting by the application of metal powder (Cu), after which the Cu shell is deposited from a sulphate bath by using a current density of about 60 amps./cm.^{2} After backing the shell with low-fusing alloy, stone, or plaster, it is ready for use. The procedure has other applications, and other metals can be deposited with the equipment. 5 references. OEH (8d)

The Adhesion of Electrodeposits. W. R. MEYER. *Monthly Review American Electroplaters' Society,* Vol. 23, Feb. 1936, pages 5-37. The force responsible for adhesion decreases rapidly (as the 4th power) as the interatomic distance increases and becomes very small at a distance as large as .0000002". This illustrates how even traces of oxide or grease films may cause peeling. Cleaning: Metal treated in an alkaline cleaner and showing no water-breaks may nevertheless be a source of peeling from (1) hydrogen embrittlement, (2) plating action of an electric cleaner, (3) presence of hydrophylic colloids such as albumin, peptone, glue, gelatine. Pickling: Acid dipping with or without current removes oxides, and cold worked surfaces and neutralizes alkaline films remaining from the cleaner. Smut resulting from undissolved constituents, as C in steel, Cu and Si in Al alloys, Cu in Zn alloys, can be avoided by selecting proper time. Temperature and concentration of acid. Rinsing: Since alkali cyanide solutions are viscous their rinsing action is slow. Acid dips should precede acid plating solutions, cyanide dips precede cyanide solutions. Plating conditions: The alkaline film which forms adjacent to cathode surface will cause formation and codeposition of hydroxides which in turn may cause hard brittle peeling deposits. Peeling may also be caused by high current density. Properties of deposit which may cause peeling are inherent stresses (Ni and Cr have high contractive tendency) and coefficient of expansion. Latter usually causes cracking rather than peeling. Thus coefficient of expansion of Zn is 4 times that of Cr and this is probable explanation of cracking of Cr direct on Zn. Diffusion of electrodeposits into basis metal occurs for Au on Pb, Cu on Al and Zn, Cd on Cu or Fe. When the alloy resulting from diffusion is brittle (as Cu on Zn) peeling results. Among the illustrations is a diagram of polished Cu showing a surface layer of amorphous metal .0000004" thick. Under this, a layer of small crystals .0002" thick, under this a transition zone .001" thick, finally the undeformed basis metal. Photomicrographs show; precipitation of Sb from solid solution in a Pb-Sb alloy, minute holes and skin on surface of a die casting, cracking of Ni deposit on Zn, hot galvanized coatings showing alloy zones, diffusion zones of Cu on Zn, distribution of deposited metals around undercuts in basis metal, and cracks in Ni deposit transmitted to Pb-Sb alloy basis metal. GBH (8d)

Modern Equipment for Ni- and Cr-plating (Organisation Moderne d'un atelier de nickelage et de chrome) J. LOISEAU. *Métaux,* Vol. 11, Feb. 1936, pages 24-30. General description of Ni and Cr plating plant at Fonderies Arthur Martin at Revin, France. Ni plating takes 12 minutes with a current density of 20 amp./dm.^{2}, for a coating 20 microns thick. Cr plating takes 5 minutes. GTM (8d)

Bronze Electrodeposits. C. BECHARD. *Metal Progress,* Vol. 29, Mar. 1936, pages 43, 94. See "The Electrodeposition of Bronze Using Bi-metallic Anodes," *Metals & Alloys,* Vol. 7, June 1936, page MA 304L/2. WLC (8d)

8e. Metallic Coatings other than Electroplating

An Electrolytic Test for Zinc Coatings on Wire. S. C. BRITTON. *Journal Institute of Metals,* Vol. 58, Jan. 1936, pages 49-60 (Advance Copy No. 724). Two tests are proposed: one an electrolytic stripping test and the other a wrapping test followed by stripping. In the stripping test the wire is made the cathode of a special cell, and a fixed current passed through the cell for a specified time, after which the sample is dipped in $CuSO_4$. If no red Cu is precipitated on the specimen, Zn coating has not been completely removed to the Fe at any spot and the wire is considered to meet the requirements. In the other test the wire is wrapped around a cylinder, the diameter of which depends on the use to which the wire is to be put, straightened, and then handled as in the other test. This test gives an indication of the brittleness of the coating. Structures of different coatings were determined by measuring voltage in cell at intervals as stripping proceeds. Voltage-time curves give an indication of the thickness of the Zn and Fe-Zn layers. Different types of curves are obtained for hot-dipped, electrolytic and galvannealed coatings. 11 references. JLG (8e)

Metallic Cementation by Means of Manganese Powder. TSUTOMU KASE. *Kinzoku no Kenkyu,* Vol. 12, Oct. 1935, pages 478-483. In Japanese. The diffusion of Mn, in the form of pulverized commercial product, into Fe, Ni, and Cu, at various temperatures between 600°-1100° C. for 1, 2, 3, and 5 hours was investigated. The hardness of the surface layer of the cemented specimens and the depth of penetration were measured together with microscopic examination, chemical analyses, and corrosion tests with various concentrated acids. It was found that Mn diffuses into the metals mentioned at temperatures above 600°, the rate of diffusion increasing with increase of temperature. In the case of Fe, the rate increases very abruptly at the A_3 point, (906° C). The relation between the weight increase of the specimen and the absolute temperature of the cementation or the duration of the treatment is given by the following exponential function,

$$W = ae^{-b/T}$$

where W is the increase of weight of specimen,
T, absolute temperature of heat treatment,
a, b, constants.

The surfaces of Fe and Ni cemented with Mn are easily attacked by concentrated acids, while that of Cu is unaffected by corrosion with dilute H_2SO_4, HCl or concentrated HCl. KT (8e)

Cementation of Some Metals by Means of Ferro-titanium Powder. TSUTOMU KASE. *Kinzoku no Kenkyu,* Vol. 13, Feb. 1936, pages 50-60. In Japanese. By means of pulverized ferrotitanium the cementation of Ti into Fe, Ni, Cu at various temperatures between 800° and 1300° C. was investigated. The depth of penetration was measured; microscopic examination and chemical analysis were carried out and resistance to corrosion against some acids studied. The following facts were found: Ti diffuses into the metals above mentioned at temperatures above 800° C., the rate of diffusion increasing with rise of temperature. The rate of diffusion into Fe, however, increases very abruptly at the A_3 point (906°). The relation between the weight increase of the specimen (Δ W) or the depth of penetration (P) and the absolute temperature of cementation (T) or the time (Θ) required for the treatment is given by an exponential function ΔW (or $P) = ae^{-b/T}$, where a and b are different constants in each case. Although the cemented surfaces are harder than the original material, they give little promise with regard to corrosion resistance. KT (8e)

New Processes in the Manufacture of Bearing Bushings with Copper-Lead Lining (Neuere Verfahren bei der Herstellung von Lagerkörpern mit Kupfer-Blei Auskleidung) KURT NISCHK. *Giesserei*, Vol. 23, Jan. 3, 1936, pages 4-7. It is difficult to make Cu-Pb mixtures adhere firmly to the material of the bushing and to prevent segregation of Pb when cooling slowly. To eliminate these inconveniences direct casting of the lining alloy on the bushing has been tried and also casting the alloy on a sheet which is then formed as a bushing. Several patented methods (French No. 714180, 680049, 785351, British No. 413932, 416371, American No. 1870867, 1956466) are discussed and described. Ha (8e)

Reactions of Iron with Molten Zinc (Ueber die Reaktionen des Eisens mit flüssigem Zink) W. PÜNGEL, E. SCHEIL & R. STENKHOFF. *Archiv für das Eisenhüttenwesen*, Vol. 9, Dec. 1935, pages 301-304. The attack of Fe by molten Zn is much stronger when $FeZn_7$ instead of $FeZn_3$ is formed. The formation of $FeZn_3$ serves to protect the Fe from further attack. No obvious relationship appeared between the composition of the steel and the Zn both and the tendency to form $FeZn_3$. SE (8e)

Sprayed Metal Coatings. Technique and Properties. E. L. MATHY. *Metal Progress*, Vol. 29, Apr. 1936, pages 52-56. Describes "metallizer gun" for spraying molten metal from wire feed into an oxyacetylene flame. The molten metal is forced out by compressed air. The particles of metal flatten on impact with surface to be coated. Any oxide film is broken and the formation of a true weld is claimed. These particles overlap each other and form a coating similar in structure to the scale of fish. Preparation of the surface is important to good coating. Costs and properties of various coatings are given. WLC (8e)

Aluminum Plating. *Metal Industry*, London, Vol. 47, Dec. 6, 1935, page 570. Resume of article by H. G. Heine in *Aluminium*, Sept. 1935. See *Metals & Alloys*, Vol. 7, Mar. 1936, page MA 136R/4. HBG (8e)

Methods of Detinning Tinplate for Examination of the Thickness and Continuity of the Alloy Layer. A. W. HOTHERSALL & W. N. BRADSHAW. *Iron & Steel Institute*, Advance Copy No. 10, May 1936, 10 pages; *Technical Publication of the International Tin Research & Development Council*, Series A, No. 37, 1936, 10 pages. The Sn layer can be removed, without attacking the alloy layer, by dissolving in Na plumbite or by an anodic treatment. The former involves immersion in the boiling solution for 3 to 5 min. Electrolytic treatment consists in treating in 5% NaOH at 30° C. The potential difference should be controlled and should not exceed 1 volt. From 10 to 20 min. is required for detinning an average sample. Weights of alloy found on several tin-plate sheets are listed. An average of 3.3 oz. of alloyed Sn per base box was found on tin plate carrying 2 lb. or less Sn per base box. Larger amounts of alloyed Sn were found with heavier coatings, the maximum being 1 lb. 1.2 oz. of alloyed Sn per base box. The alloyed layer was found to be highly porous. JLG (8e)

A Study of the Origin of Porosity in the Tin Coating of Tinplate. A. W. HOTHERSALL & J. C. PRYTHERCH. *Iron & Steel Institute*, Advance Copy No. 11, May 1936, 15 pages; *Technical Publication of the International Tin Research & Development Council*, Series A, No. 38, 1936, 15 pages. Tin plate of various grades was examined with a view to correlating position of pores in the Sn coating with visual imperfections or peculiarities of the tin plate. Pores were located by slight rusting of the plate in distilled water. Their position was marked and the rust removed by a brief cathodic treatment in alkali. The plate was then examined microscopically. In finished plate, from 30 to 50% of the pores were found in scratches produced in the final cleaning and polishing. Plate with less than 2 lb. of Sn per base box had scruff lines (crystals of Fe-Sn alloy) at right angles to the direction of travel of plate through tinning bath. In plate that had not passed through the cleaning or polishing rolls, pores were chiefly located in the scruff bands and grease marks. Scruff bands were not seen in plate with more than 3 lb. of Sn per base box but the largest grease marks of saucer shape were grouped in periodic bands at right angles to the direction of tinning. Practically all of the pores not associated with scratches were located in these bands. Discontinuities in the Sn coating could be seen under the microscope at the site of the pores. The alloy layer left after solution of Sn was found to be highly porous. Porosity could be increased by slight stretching. JLG (8e)

■ 8f. Non-Metallic Coatings ■

Synthetics for Automotive Finishing in U. S. A. HERBERT CHASE. *Synthetic & Applied Finishes*, Vol. 6, Nov 1935, pages 196-197, 200. Synthetic enamels have long been preferable to lacquers for running gear and other chassis parts, and recently have displaced nitrocellulose lacquers in finishing passenger car bodies. Modern "straight synthetics" dry free of dust in 2 hours without baking. Usually an overnight drying is allowed, except for 2-coat jobs, when the second coat is sprayed on after the 1st has dried ½ hour, and both coats allowed to dry overnight. Variations in application are described and advantages of synthetic enamel over lacquer for automotive finishing are cited. FPP (8f)

Investigations of Phosphate Protection for Ferrous Metals (Richerche sui bagni di protezione fosfatica per metalli ferrosi) O. MACCHIA. *Industria Meccanica*, Vol. 18, Feb. 1936, pages 81-85; Mar. 1936, pages 141-143. The principal baths used for producing phosphatic protection of ferrous metals are reviewed and described in detail, and patents and patented processes cited. 70 references. Ha (8f)

Pretreatment of the Base for Coats of Paint (Vorbehandlung des Untergrundes für den Anstrich) FR. KAPPLER. *Zeitschrift Verein deutscher Ingenieure*, Vol. 80, Feb. 15, 1936, pages 183-185. The adhesion of paint depends to a great extent on the initial treatment of the base: The adhesion of paint was measured on surfaces cleaned by grinding, brushing with steel brush, and sand blasting of different degrees. In general, cleaning with the brush is sufficient for ordinary structures to be protected against weathering, but bridges, weirs, etc. should be sand blasted before painting. Pickling should be applied only for single pieces and where subsequent cold working is required; it should not be employed in composite pieces as the pickling liquid enters the interstices. Ha (8f)

Rapid and Economic De-enameling Process (Procédé rapide et économique de Désémaillage) J. NAPPEE. *Usine*, Vol. 45, Mar. 12, 1936, pages 29-30. Difficulties of de-enameling and current methods used are discussed; the latter were not very economical. A new method and equipment are described which do not attack the base; caustic soda is at first heated to 530°-550° C. to free it from its water of crystallization. Such a bath dissolves enamel dipped into it in about 45 sec. and no harmful gases are developed although slight sputtering takes place against which the workmen must be protected. The de-enameled pieces are rinsed in cold water. The process is said to be cheaper than dissolving in acid or removal of the enamel by sand blasting. Ha (8f)

Anodic Oxidation. J. W. RUSHTON. *Aluminium & Non-Ferrous Review*, Vol. 1, May 1936, pages 380-381. Brief notes on applications of the process. JCC (8f)

Iron Black and Iron Hammer Scale as Pigments for Antirust Paint (Les Noirs de Fer et l'Oxyde de Fer des Battitures comme Pigments pour Peintures antirouille) H. RABATE. *Usine*, Vol. 45, Apr. 23, 1936, pages 37-39. The use of the various Fe oxides, with exception of FeO due to its chemical instability, as pigments, is discussed and the widening use of artificial oxides made from scale according to several patents (French No. 532400, DRP 25683, 389161, 394131) is described. Vehicles, thinners, and admixtures especially Al powders to obtain special appearances are described. Ha (8f)

Blisters in Enamel and Their Causes (Emailblasen und ihre Ursachen) LUDWIG STUCKERT. *Forschungsarbeiten über Metallkunde und Röntgenmetallographie*, No. 11, 1934, pages 25-46. A discussion of the causes of defective enamel on steel sheet. Defects may be attributable to the enamel, the steel or to the processing. Typical defects are shown. JLG (8f)

Blisters in Enamel Over Welds (Die Blasenbildung im Email auf Schweissnähten) M. v. SCHWARZ & F. GOLDMANN. *Forschungsarbeiten über Metallkunde und Röntgenmetallographie*, No. 11, 1934, pages 1-9. Discusses causes of blisters and gives following suggestions for avoiding them. Avoid steel sheet containing slag, gas, or S inclusions. Use narrow and regular overlap, avoid leaving sharp corners, also slow welding that changes structure of sheet near weld. Enameling too soon or too long after welding is inadvisable. Avoid sheet that has been critically cold rolled after final annealing or sheet that has been annealed above the upper critical temperature. JLG (8f)

Rust-proofing and Paint-adherence. F. P. SPRUANCE. *Automobile Engineer*, Vol. 26, Jan. 1936, pages 41-42. See *Metals & Alloys*, Vol. 7, May 1936, page MA 246L/6. Ha (8f)

Effect of Mill Additions on the Thermal Expansion of Sheet-Iron Ground Coat Enamels. R. L. FELLOWS & E. E. HOWE. *Journal American Ceramic Society*, Vol. 19, Apr. 1936, pages 109-111. 13 batches of enamel of varying composition were investigated. The results are given in curves and tables for 2-frit ground coat. WB (8f)

Metallurgical Control in the Production of Non-Ferrous Sheet and Strip. A. F. Dunbar. *Metal Industry,* London, Vol. 47, Dec. 20, 1935, pages 603-607; Dec. 27, 1935, pages 630-632. A lecture by the metallurgist at the Ammunition Factory of the Munitions Supply Board of Australia. Describes the foundry and rolling mill practice at the ammunition factory of the Munitions Board with particular reference to controlling quality. Listed as representative of the various classes of alloys produced are brasses, gilding metal, platers' metal, phosphor-bronze, Al-bronze, cupro-Ni, Ni-Ag and key-metal. Their approximate composition and uses are indicated. The quality of the raw material used and the effects of the several impurities on the different alloys are discussed. Foundry equipment, dressings for ingot molds, fluxes used for non-ferrous alloys, couples, and typical pouring temperatures are briefly discussed. The principal causes of defects in the finished material that are attributed to the foundry are (1) too high pouring temperatures which result in coarser grained material and produce cracks on rolling, particularly on the break-down rolls, (2) too low a pouring temperature, which results in (a) "double-strip" caused by a so-called "loose centre," i.e., a central cavity not observed during cropping, and (b) "blisters," caused by trapped gas during solidification, and (3) incorrect feeding, which results in subsurface cavities. The methods of sampling for chemical analysis are indicated. The rolling mill operation is described from the surfacing of the ingot prior to rolling to the finished material which is supplied in a number of degrees of hardness. The different physical testing methods used include (a) Shore hardness, (b) Erichsen cupping tests, (c) Vickers hardness, (d) tensile tests, and (e) microscopic examination. For the latter work a Vickers projection microscope is used because of its several advantages. HBG (9)

W. A. TUCKER, SECTION EDITOR

The Upper and Lower Yield Points and the Breaking Strain. G. Welter. *Metallurgia,* Vol. 13, Apr. 1936, pages 183-187. Describes further experiments that show phenomenon of upper and lower yield points to be attributable to the testing machine and not to the material tested. At the yield point an accelerated yielding of the material takes place, due to which no drop in load from an upper to a lower load stage of the test bar results. Similarly, the decline in loading from the maximum load to the breaking load on the material is a matter of a peculiarity of the machine, according to which the actual conditions obtaining in the tensile test are not reproduced true to reality. JLG (9b)

Does Upper and Lower Yield Point Have Actual Existence? G. Welter. *Metal Progress,* Vol. 29, Mar. 1936, pages 66-67. Due to small motion of head of most testing machines corresponding to a large load a sudden yielding of specimen results in drop on autographic record of load-extension. Where precautions are taken by design of machine or application of a dead load such drops in load are not recorded and the load continuously increases through the yield point. WLC (9b)

Mechanical Tests for Engineering Materials. A. M. Roberts. Draughtsman Publishing Co., Ltd., London, 1936. Paper, 5½ x 8½ inches, 89 pages. Price 4s.

In the introduction, the author states "The excuse for introducing yet another publication on this subject is to be found in the need for a brief treatment giving concisely the methods and purposes of the more usual forms of test, which it is hoped will be sufficiently comprehensive to meeet most of the needs of the designer or draughtsman without introducing details and arguments, which are only of real value to the person actually engaged in testing. The pamphlet is, therefore, written specifically for the engineer and draughtsman who, unfamiliar with testing methods, meets the problem of deciding what tests it is necessary to apply to the machine or structural part which he has designed and for which he wishes to insure a satisfactory performance under the service conditions with which he is acquainted."

The pamphlet describes various tests and testing machines (English): tensile, bend, hardness, impact, transverse on cast iron, fatigue, creep, tests on welds and cement, test procedure. Richard Rimbach (9b) -B-

"ROCKWELL"
HARDNESS TESTER

Do not judge either the sensitivity or durability of the "ROCKWELL" by one of the early and primitive models that was made ten or eleven years ago.

During the past five years the mechanical design of the "ROCKWELL" has been very different from that of early models.

The sensitivity desired in hardness testing today was not thought of a dozen years ago, but you may have it now and at the same time have a longer wearing machine.

Machine à enregistrement graphique pour l'essai mécanique des métaux) PIERRE CHEVENARD. *Revue de Métallurgie,* Vol. 33, Apr. 1936, pages 280-287. Mechanical features of a device registering strain stress diagram in ink. The principles involved are identical with those formerly described (*Bulletin de la Societe d'Encouragement pour l'Industrie Nationale,* Jan. 1935, page 59) but the size of specimens is larger. The device is applicable to tensile, shear and bend testing. JDG (9b)

Mechanical Testing of Aluminum and Aluminum Alloys (Mechanische Prüfung von Aluminium und Aluminiumlegierungen) R. IRMANN. *Aluminium,* Vol. 18, May 1936, pages 192-202. The test methods for determining the static properties of Al and Al alloys are reviewed, preparation of specimens is described, and a tabulation given showing which of the different tests (tensile, hardness, bending, impact, deep-drawing) can be made on the material in the form of sheets, wire and profiles. The German standards and definitions are described. Ha (9b)

International Standardization of the Impact Bending Test (Die zwischenstaatliche Normung der Kerbschlagbiegeprobe) A. LEON. *Montanistische Rundschau,* Vol. 27, May 16, 1936, pages 2-5. A summary of the efforts made to standardize the impact bending tests at the various international congresses held since 1906 in the field of materials testing. Much space is given to the 1933 meeting at Düsseldorf, where it was decided to carry out tests with 2, 3 and 5 mm. notches, to determine the most suitable depth of notch. These tests were to be carried out in several countries. The results of the French tests are given in the article; they show that the 5 mm. notch is the most satisfactory. BHS (9b)

An Improved Method for Preparing Cast-Iron Transverse Test Bars. A. I. KRYNITSKY & C. M. SAEGER, JR. *Bureau of Standards Journal of Research,* Vol. 16, Apr. 1936, pages 367-384. The importance of preparing cast-Fe transverse-strength test bars free from "burnt-on" sand and surface defects is discussed. A molding material and casting technique which will produce such test bars in green-sand molds has been developed. Test bars 0.75", 1.2", 1.5", and 2.2" in diameter and 23" in length were cast in top-poured and bottom-poured vertical molds, horizontal molds, and horizontally inclined molds. The effect of maximum heating temperature on the transverse breaking strength, hardness, primary structure, and microstructure of test bars made by these methods was investigated. Test bars cast in bottom-poured vertical molds yielded the most consistent results. The transverse breaking strength of the irons investigated increased with an increase of the maximum heating temperature, regardless of the casting method employed. A finer primary structure and finer graphite and pearlite constituents were found to be associated with higher transverse strength. WAT (9b)

Determination of the Maximum Temperature Effect During Cross Sectional Reduction of Wire Previously Annealed in an Inert Gas (Bestimmung des Temperaturmaximus in der Umgebung einer Querschnittseinschnürung eines in eimem Inerten Gas Geglühten Drahtes) LEOPOLD PRÁSNIK. *Zeitschrift für Physik,* Vol. 99, Apr. 2, 1936, pages 710-713. Derivation of equations is given to show the maximum temperature rise for different reductions in cross sectional area for W wire which was previously annealed in an inert gas. FHC (9b)

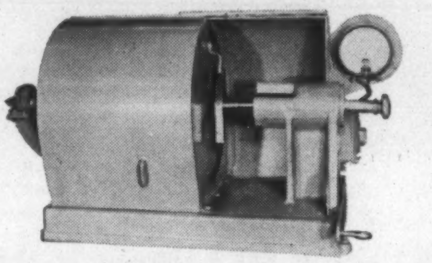
Leadership
in TESTING
methods and equipment

●

Because Southwark has brought together developments and designs for all that is strictly up-to-the-minute in physical testing, this organization has become a clearing house for the exchange of advanced ideas and methods related to this subject.

Take, for example, one subject—the study of the effect of impact on materials. This is being studied from different angles other than that of the classical notched bar.

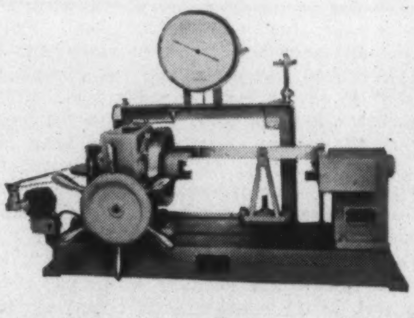
Torsion Impact



carries impact testing into the high hardness ranges with a high degree of reproducibility—showing in tool steels, for instance, the toughness under various conditions of quenching and drawing. Such impact tests are applicable to all brittle or hard-surfaced materials. They are also a study of the effect of shock on materials stressed in torsion, such as shafts and axles. These tests, in addition, are valuable in the study of the effect of surface corrosion.

Torsion Impact is used principally by steel companies, such as: Bethlehem, Allegheny, American Steel and Wire, Vanadium, Halcomb, Carpenter, Republic and others.

Static Torsion



—for hard and brittle materials. There are two schools of thought relative to the tests on hard metals, such as tool steels. One supports the torsion impact test advanced by the Carpenter Steel Company. The other supports the static torsion test advanced by Emmons of the Cleveland Twist Drill Company.

Each studies the effect of drawing temperature on toughness, but in a distinctly different way.

An ingenious precision torsion machine following Emmons' design has been developed for commercial use.

Dr. Sauveur of Harvard has also approached the study of materials from the point of view of torsion. He has found a relation between creep values and torsion values under constant load at elevated temperatures, and has designed a simplified torsion machine—autographically developing the load-twist curve by means of this machine and exploring very thoroughly the whole subject of torsion. In addition—Southwark's approach toward the study of the damping properties of materials (also known as dynamic ductility) is by the way of torsion. This has had much discussion in technical literature.

10. METALLOGRAPHY

J. S. MARSH, SECTION EDITOR

The Constitution of Binary Alloys (Der Aufbau der Zweistofflegierungen) M. HANSEN. Julius Springer, Berlin, 1936. Cloth, 6½ x 9½ inches, 1100 pages. Price 87 RM.

This is one of the most valuable reference books in metallurgy which has appeared in many years. Dr. Hansen has attempted—successfully—to assemble in one volume all of the information available on the constitution and structure of the binary systems of the metals. The effort must have been prodigious: no less than 828 binary systems are discussed, though of course constitution diagrams are not available for all of these. An effort was made to have the references complete up to the fall of 1935, though doubtless this date must not be taken as precise, with the difficulties in obtaining journals promptly, especially from distant countries.

Each binary system is discussed separately, with references given to all of the original papers. Where possible, complete temperature-composition diagrams are given, frequently reinforced by detail drawings on a larger scale of small sections. The discussion is as critical as it can be: work which seems untrustworthy is given little or no weight; of course in the end real criticism requires a repetition of the experimental work, and in lack of this an author can only summarize that which appears in the literature, taking most of it on faith. In many cases, where disagreement obtains, the author reproduces diagrams from a variety of authors, such as in the case of the region surrounding the β phase in the Cu-Zn system, the Wüstite phase in the Fe-O system, and the Al-rich terminal solid solution in the Al-Zn system.

In addition to the obviously metallic systems, systems of Ti, Se, Te, S, P, B, C, N, O, and H are included because of their obvious interest to metallurgists. It is surprising to discover the fact that a number of the praseodymium systems have been rather thoroughly studied by several Italian workers!

Much of the best work on the constitution of metal systems has appeared in the last 15 years. The earlier work was largely performed by thermal analysis and microscopic examination of specimens. Thermal analysis is now rarely used, apart from the determination of liquidus temperatures, and the newer X-ray diffraction methods and modern precision dilatometric methods are used very extensively. With improvement in methods and in materials and with a rapidly growing professional class, ever better trained, the quality of recent work has been very high. The author discusses this newer work thoroughly; he gives in each case the lattice structures of the phases obtaining in the system when these are known.

It is, of course, impossible to tell whether the work is complete,—the critic would have to do as much or more work than the author to tell this! I have discovered no omissions, and I have been surprised several times in the completeness of the references for the systems about which I happen to know something. The treatment of the constitution of the alloys of iron is not as complete as that given in the *Alloys of Iron Monographs,* but the treatment given seems adequate.

The book is delightfully orthodox in its presentation of constitution diagrams: changes from ferromagnetism to paramagnetism are indicated by single *dotted* curves, not to be confused with the boundaries of fields of true heterogeneous equilibrium which are drawn as *solid* curves, as, for example, in the systems Fe-C, Fe-Ni, Cu-Ni, Co-Ni, etc.; nor are solid conjugate curves drawn for those mysterious changes in the solid state leading to the formation of superstructures, as in the Au-Cu, and Cu-Pd systems.

The book is beautifully printed. The arrangement is extremely convenient: the systems are arranged alphabetically according to the symbol for the element appearing first in the alphabet; in this way any system may be readily found without reference to the excellent index. The book will be of great service to the metallurgical profession—it is far superior to all previous efforts along the same line; it has already proved of value in my own laboratory, for it has permitted two research men to select a series of systems for their purposes without the months of literature research which otherwise would have been necessary. How the author purposes in the future to keep the summary up-to-date, I don't know, but some effort should be made for the value of the book is too great to be slowly lost through becoming obsolete. Perhaps Dr. Hansen will similarly honor the metallurgical profession by presenting a like book on the constitution of ternary systems.

The price of this book is very high,—87 marks, and I fear that only libraries—and not all of them—will be able to afford it, yet every research metallurgist will require it for continual use and despite its price it must be recommended without any reservation and with full commendation for a difficult and arduous task accomplished with distinction. Robert F. Mehl (10) -B-

Hydrogen in Steel (Wasserstoff im Stahl) HEINRICH PLOUM. *Chemische Fabrik,* Vol. 9, Apr. 17, 1936, pages 173-177. Steel is capable of dissolving H if the latter be in the atomic state, a condition that may be realized in one of two ways: either by splitting of H molecules into atoms along the surface of a piece of steel heated in a H atmosphere or by the electrolytic evolution of H when steel is dissolved in acid or is treated cathodically without dissolving. An extensive review of the literature concerning both of the foregoing solution mechanisms is presented. Much of the dissolved H escapes at room temperature, and its escape is accelerated with rising temperature. Measurements of H evolution at room temperature show that the original rate of escape is high, but drops as the material becomes impoverished, a certain residue remaining finally. Further evolution occurs on heating. Investigation of the distribution of H across sections of wire and cylinders of varying thicknesses, cathodically treated, showed the surface concentration to be much higher than the internal, while the H absorbed by heating samples in H_2 atmosphere was distributed evenly across the section. The literature and mechanism of H embrittlement are reviewed, and the author's own observations, particularly with Fe wires, are presented. 25 references. FPP (10)

Ferrite Banding in Forged and Rolled Steel. A. V. PROHOROFF. *Metallurgia,* Vol. 13, Apr. 1936, pages 179-181. Reviews theories of ferrite banding and cites experimental study in which plates of different steels were welded together and then heat treated. Results proved that banding resulted from differences in concentration of Si, Mn, Ni or other elements. Some elements cause C increase and others C decrease where they are segregated. It is suggested that ferrite banding may be prevented by balancing the composition of a steel so that the alloying elements which segregate in interdendritic spaces oppose each other in their influence on the direction of C rediffusion on cooling. JLG (10)

The Present Status of Ferromagnetic Theory. R. M. BOZORTH. *Bell System Technical Journal,* Vol. 15, Jan. 1936, pages 63-91; *Electrical Engineering,* Vol. 54, Nov. 1935, pages 1251-1261. This article presents the current conceptions of the nature of ferromagnetism in readily understandable form. Briefly, it is held that the origin of ferromagnetism lies in the magnetic moments of the circulating and spinning electrons of the atom. In a nonmagnetic atom these moments are mutually neutralized within the atom but in a ferromagnetic atom there exist uncompensated electron spins which magnetically polarize the atom. For an element to be ferromagnetic however, not only must its atom contain uncompensated spins, but these must also be parallel from atom to neighboring atom, necessitating powerful "exchange" forces which depend both on the number of uncompensated spins and the distances between them. Even with no applied field these forces hold all electron spins parallel over small regions or "domains" of about 10^{-8} cm.^{3} in volume. In unmagnetized material the spin directions may vary from one "domain" to another. In the process of magnetization there is (1), at low field strengths, a growth of one "domain" at the expense of another, followed by (2), sudden changes of the "domain" spin direction to those directions of easiest magnetization in the crystal lattice which are most nearly parallel to the applied field direction and finally (3) a rotation of the electron spins in each "domain" out of the stable position toward the field direction. These three stages correspond to the initial, middle, and top portions of the magnetization curve. Magnetization may be helped or hindered by homogeneous axial strain because of the magnetic action between neighboring atoms. This action being balanced by electrostatic forces there is bound to be a change in atomic spacing when the material is magnetized (magnetostriction). Material in which local strains are directed at random are hard to magnetize or demagnetize. The effect of local strains on initial permeability can be calculated fairly closely but other properties such as maximum permeability may be estimated only qualitatively at present. HFK (10)

Formation of Spherical Eutectic Inclusions in Alloys (Die Bildung Kugelförmiger eutektischer Einschlüsse in Metallegierungen) W. GELLER. *Metallwirtschaft,* Vol. 15, Feb. 7, 1936, pages 141-142. Spherical eutectic inclusions found especially in high purity Al alloys are droplets enclosed by the matrix during rapid cooling. It is shown that their formation is favored by fast cooling from just above the solidus line and when the temperature range between the liquidus and solidus is small. Their occurrence is also demonstrated in an Fe alloy containing 28% Co and 30% Sn. GD (10)

New Methods for Constitutional Studies (Neuere Verfahren der Konstitutionsforschung) G. GRUBE. *Zeitschrift für Metallkunde,* Vol. 27, Sept. 1935, pages 194-195. Examples are given which show use of magnetic-susceptibility measurements over a range of temperature in determining phase changes for ferro-, para-, and dia-magnetic materials. A simple-but-accurate apparatus for such measurements is described. GD (10)

Variations in Work-function Emission at the Melting Point of Metals (Zur Frage der Austrittsarbeitsänderungen im Schmelzpunkt der Metalle) H. KURZKE. *Zeitschrift für Physik,* Vol. 98, Feb. 3, 1936, pages 684-691. Observations of the electron emission and the photoelectric effect show that for certain metals in the region of their melting points, the work function is greater in the liquid than in the solid state. FHC (10)

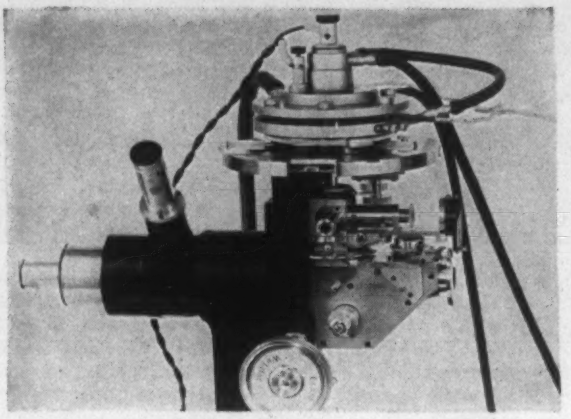
Inner Potentials of Crystals and the Electron Diffraction. W. E. LASCHKAREW. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1081-1095. The present state of the question of the inner or the "effective" potential in relation to electron diffraction is discussed. The "effective" potential is not a constant but increases with the order of the diffracted reflection. A new method for calculating the potential distribution in the grating and the mean grating potential from X-ray data is given. The independence of the "effective" potential value from the presence or absence of free electrons in the grating is pointed out. Difficulties are discussed which arise in the determination of the "effective" potential when using diffraction of slow electrons. By considering the temperature factor it is possible to arrive at unique reflection orders and a unique determination of the "effective" potential. 26 references. PRK (10)

Investigation of the Mg-Cu-Al System, Especially the $MgCu_2$-$MgAl_2$ Section (Untersuchungen im System Mg-Cu-Al, speziell auf dem Schnitt $MgCu_2$-$MgAl_2$) F. LAVES & H. WITTE. *Metallwirtschaft,* Vol. 15, Jan. 3, 1936, pages 15-22. Thermal, X-ray, and microscopic studies were made on alloys along the Mg-Cu_2-$MgAl_2$ section at compositions from 0-85 mol. % $MgAl_2$ with 5% increments. Beyond 45% the alloys prepared by melting were not homogeneous and specimens were made by annealing compressed powders of $CuAl_2 + Mg + Al$. A large part of the Al corner was roughly explored with these powder samples. It was found that the cubic $MgCu_2$ formed a solid solution up to 35% $MgAl_2$ with a regular increase in lattice constant. From 35 to about 52% $MgAl_2$ the hexagonal lattice of the $MgNi_2$ type was found, but annealing at 500° produced the hexagonal lattice of the $MgZn_2$ type, which was also formed in the alloys up to 60% $MgAl_2$. It was evident that some crystallographic mechanism controlled the transformation from $MgNi_2$ to the $MgZn_2$ lattice. Other ternary compounds corresponding to the formulas $Mg_2Cu_2Al_5$ and $Mg_3Cu_7Al_{10}$ were found. GD (10)

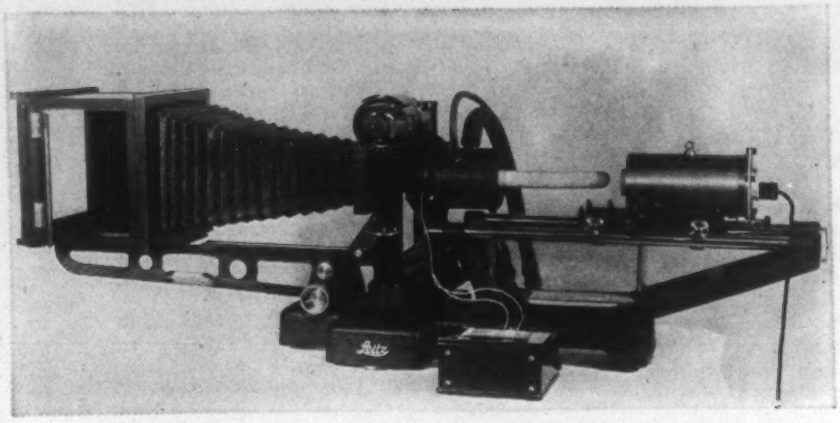
The Structure of Polished Metal Surfaces. C. S. LEES. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1102-1106. Surfaces of Cu and Au were polished. 3 methods of polishing Cu were used and one of polishing Au. Surfaces were etched electrolytically and photographed by electron diffraction. The Beilby layer was found to be separated from the non-oriented polycrystalline interior of the metal by a layer of oriented crystals. The thicknesses of the 2 layers were estimated on Cu. The amorphous layer extended from 0 to 45 A.U. and the oriented layer extended from 0 to 300 A.U., according to the polishing technique on Cu. Au has a much thicker oriented layer than Cu. The orientation appears to be due to deformation of the crystals by compression. The actual surface cannot consist of crystal faces. 8 references. PRK (10)

Leitz

SERVES INDUSTRY OPTICALLY



Leitz Vacuum Heating Chamber



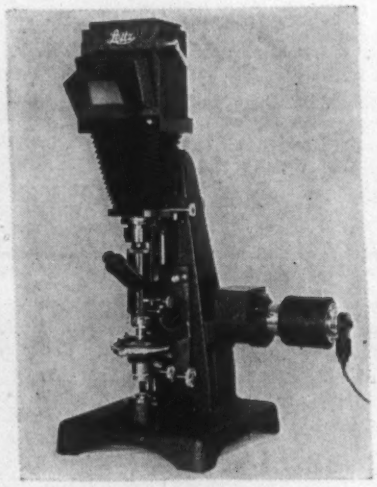
Leitz Automatic Recording Dilatometer

More and more are practical problems concerning the production and use of metals being solved with the aid of the microscope in one or more of its many variations. It is the key that unlocks the door to facts concerning metals that hitherto were deep mysteries or not even suspected.

LEITZ serves industry optically.

The PANPHOT, for example, is a combination microscope and camera that just about covers every requirement of applied microscopy. The user can make visual observations—can take both micro and macro photographs—can make micro-drawings and projections. He may use all methods of illumination, changing them quickly and in any sequence. Both extensive objects and reflecting objects may be studied and photographed. And there are many other uses for the LEITZ PANPHOT. It is indeed a most useful instrument for the metallurgist and metallographer.

The Vacuum Heating Chamber is another recent LEITZ development with wide possibilities in the metal-working industries. It is an apparatus attachable to the LEITZ Micro-Metallograph which permits observation of micro structures in metals while heated as high as 1150 deg. C.



Leitz Panphot

The DILATOMETER discloses and records photographically not only the relative expansions of various metals when heated but records critical points where physical or crystalline changes occur.

These three are but a few of the many optical and other instruments LEITZ makes for the metal-working industry. We shall be glad to send you descriptive literature and to assist you in making better use of optical instruments.

Etch Planes of Tin. L. W. McKeehan & Harold J. Hoge. *Zeitschrift für Kristallographie,* Vol. 92. Dec. 1935, pages 476-478. In English. Etch planes of Sn were developed by etching with HCl and small additions of $KClO_3$. For alloys with 0.6% Sb the acid had to be dilute. Alloys with Cd and Ga additions up to 1% were intermediate in resistance to attack between these extremes. The sharply defined etch planes are listed. They were accurate enough to dispense with time-consuming X-ray analyses. EF (10)

Manner of Reaction of Carbide Etching Reagents (Wirkungsweise der Karbidätzmittel) R. Mitsche. *Archiv für das Eisenhüttenwesen,* Vol. 9, Dec. 1935, pages 311-312. For carbide etching the presence of an oxidizing agent along with the alkali is necessary. A suitable reagent proved to be $KMnO_4$ in KOH or NaOH. Ferrohydroxide formed on the cementite by the attack of the caustic is oxidized to ferrihydroxide, which deposits on the cementite and gives it a dark color according to the length of etching. The Ternary System FeO-MnO-SiO₂. W. R. Maddocks. *Iron & Steel Institute, Carnegie Scholarship Memoirs,* Vol. 24, 1935, pages 51-68. The system FeO-MnO-SiO_2 was studied using various slags made from pure FeO, MnO, and SiO_2, and the melting surface of a wide range of compositions was determined. A ternary eutectic having the composition 50% FeO, 20% MnO, and 30% SiO_2 was observed which melts at 1170° C. A ternary diagram is constructed, and the usefulness of this in understanding the behavior of acid open-hearth slags and the deoxidation of steel is given. Thermal analyses were made of pure melts contained in Mo crucibles. A differential Mo-W thermocouple connected to a galvanometer served for indicating thermal arrests and a Mo-W couple connected to a potentiometer indicated temperature. 10 references. CW (10)

Relation Between Diffusion and Structure of Solid Alloys (Beziehung zwischen Diffusion und Aufbau fester Legierungen) W. Seith & A. Keil. *Zeitschrift für Metallkunde,* Vol. 27, Sept. 1935, pages 213-216. With discussion. A survey of diffusion experiments shows that the temperature dependence of diffusion is given by the equation $\ln D = A - \frac{Q}{RT}$ where A and Q are constants. The rate of diffusion of component A in matrix B will be the greater the closer B is to its melting point, both the rate and the melting point being related to the vibrational energy of the lattice in the same way; thus the self-diffusion of Pb at a given temperature is increased by the addition of Bi, which lowers the melting point, but not by Tl which raises it. Similarly diffusion is markedly rapid during recrystallization and during allotropic transformation. The rate of diffusion of B in A is inversely proportional to the tendency of B to form solid solutions in A, as shown by studies of a series of Pb alloys. Material transport, corresponding to that calculated for C with a double positive charge, is shown if carburized Fe is heated above Ag by a direct current. GD (10)

Investigation of the Heats of Transformation of Iron (Untersuchung über die Wärmetönung bei den Umwandlungen des Eisens) H. Steinwehr & A. Schulze. *Zeitschrift für Metallkunde,* Vol. 27, Dec. 1935, page 289. Corrections to the article of the same title, *Zeitschrift für Metallkunde,* Vol. 27, June 1935, page 129. FNR (10)

Precipitation from Supersaturated Solid Solutions Across a Temperature Gradient (Die Ausscheidungen aus übersätigten Mischkristallen in einen Temperaturgefälle) G. Tammann & W. Boehme. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 226, Dec. 31, 1935, pages 87-91. A method is described for imposing a nearly linear temperature gradient on a rod of metal (in this case Cu with 6.1% Ag and duralumin). The rod is thereafter surveyed for hardness and the temperature corresponding to the point of maximum hardness is determined Apparatus consists of a Cu block heated to desired temperature and heat is conducted to 100-mm. long rod to be tested, through end screwed in Cu block. The other end of rod is clamped to a Cu block, water cooled. Thermocouples are placed in the rod at both ends and in center. A heat insulating sheath covers the rod between the Cu blocks. Curves are given for the 2 solid solutions investigated. On polishing the length of the rod and etching, the regions of precipitation could be determined with microscope. In the Cu-Ag alloy after 10 hrs., precipitation begins at about 210° C. and at 250° C. is visible under microscope; maximum hardness occurs at 300°-350° C. For the duralumin (4% Cu, 0.5% Mg, 0.5% Si) after 3½ hrs., maximum hardness occurs at 167°-200° C. and precipitate at 700 × becomes visible at 300° C. There is not an exact correspondence between hardness and precipitated phase as is corroborated by X-ray investigations (Göler & G. Sachs, *Zeitschrift für Metallkunde,* Vol. 19, 1927, page 90). Discussion of precipitation hardening and lattice parameter follows. WB (10)

Some Recrystallization Phenomena (Quelques phénomènes de recrystallisation) A. E. van Arkel. *Revue de Métallurgie,* Vol. 33, Mar. 1936, pages 197-202. A summary. When crystals slide along their cleavage planes the crystallites adjoining them turn on an axis perpendicular to the direction of rolling. This produces distortion in space lattice, which is never restored by drawing. High temperature to which a metal can be subjected reduces the friction between distorted crystallites, and they return almost to their original position. In recrystallization, atoms rearrange themselves instead of whole crystallites. Recrystallization depends on the number of nuclei of crystallization and these are controlled by the amount of deformation. Linear speed of recrystallization is a function of deformation and temperature. Sheets were punch marked and stretched to produce strain concentration at the edges of these marks. These start large grains in annealing. Sheets in process of recrystallization, strained and annealed, are composed of large crystals only. The same deformation which was sufficient to start grain growth on original sheets has no effect after sheets were recrystallized, indicating that small deformed crystals do not act as crystallization nuclei. Undeformed grains cannot be considered as nuclei. In transition from α to γ state the number of nuclei is independent of the size of crystals, untransformed α forming a number of transition points increasing with the state of deformation. Crystallization nuclei in undeformed α act as transition nuclei. In Al secondary recrystallization takes place after a deformation of 30% and annealing at 600° C. producing thousands of small crystals oriented similarly in areas which were occupied by original grains before deformation. On additional heating they unite in grains corresponding both in shape and orientation to the original. The phenomenon can occur only when certain conditions are fulfilled. JDG (10)

Silver-gallium Diagram (Das Zustandsdiagramm des Systems Silber-Gallium) Friedrich Weibke, Karl Meisel & Lotte Wiegels. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 226, Feb. 7, 1936, pages 201-208. Thermal analysis, diagram, and X-ray data are given. Experimental work and phases found are discussed. WB (10)

Information on Metallurgical Processes Obtained by Radioactive Experiments (Nachweis metallkundlicher Vorgänge durch radioactive Verfahren) O. Werner. *Zeitschrift für Metallkunde,* Vol. 27, Sept. 1935, pages 215-219. A qualitative picture of the diffusion of emanation through the metal lattice is developed whereby only the lattice atoms having the highest vibrational energy have an important influence on the heavy emanation. As a consequence of this the temperature coefficient of the diffusion of emanation is inversely proportional to the Debye characteristic temperature of the metal. Due to this importance of vibrational energy of the matrix, grain boundaries have a marked influence, and any process altering the energy characteristics of the material, such as mechanical work, precipitation, transformations, recrystallization, sintering of powdered metal, can be observed by radioactivity experiments. The presence of impurities in the material, especially gases, must be avoided. GD (10)

The Effects of Heat Treatment on Carbon Steels. E. Widdowson. *Machinery,* London, Vol. 47, Feb. 6, 1936, pages 557-560. General. WB (10)

Determination of Best Hardening Temperature for Duralumin Alloys (Versuche zur Ermittlung der günstigsten Aushärtungstemperatur bei Durallegierungen) U. v. Scheidt. *Zeitschrift für Metallkunde,* Vol. 27, Dec. 1935, pages 275-277. Because homogenization of duralumin is most readily accomplished at the highest temperature below that of the solidus, and, because small variations in the Si, Mg and Mn, as well as the Cu content of the alloy have pronounced effects upon the location of the solidus, the heat treating temperature of duralumin should be adjusted to conform with the requirement of each alloy. Four commercial duralumin alloys analyzing A (Cu 4.12%, Mg 0.84%, Si 0.23%, Mn 0.52%), B (Cu 4.21%, Mg 0.49%, Si 0.34%, Mn 0.35%), C (Cu 3.63%, Mg 1.07%, Si 0.58%, Mn 1.12%) and D (Cu 4.07%, Mg 0.74%, Si 0.38%, Mn 0.63%) were each subjected to 20 minute homogenizing treatments at 10 temperatures ranging from 493° C. to 576° C., and were quenched in water at room temperature. After aging at room temperature for 2 to 3 weeks they were tested to determine the resulting values of yield point (0.02 and 0.2% extension), ultimate strength, elongation, and bend count. By plotting the values of the mechanical properties of each alloy against homogenizing temperature, the most favorable temperature for the treatment of each alloy was shown to be: A 510° ± 2.5° C.; B 515° ± 2.5° C.; C 505° ± 2.5° C.; and D 512° ± 2.5° C. Loss of strength through "burning" occurred at A 530° to 535° C., B 538° C., C 520° to 521° C., and D 533° to 535° C. The following empirical formula for computing the best homogenizing temperatures for duralumin of various compositions was developed: $t = [548 - (5.65 - \%\ Cu) \cdot 9.04] - (40.3 : \%\ Mg + 31099 \cdot \%\ Si - 32.5 \cdot \%\ Mn) \pm 2.5°\ C.$ FNR (10)

The Irreversibility of the Iron-nickel Alloys and Their Equilibrium Diagram (Die Irreversibilität der Eisen-Nickel-Legierungen und ihr Gleichgewichtsschaubild) E. Scheil. *Archiv für das Eisenhüttenwesen,* Vol. 9, Sept. 1935, pages 163-166. The irreversible field in Ni steels is wide and at a certain temperature range results in a transformation. The irreversible field is attributed to a combination of fast lattice changes and slow changes in composition by diffusion. From the measurements 2 hitherto undetermined points on the Fe-Ni diagram were determined. With the aid of these points the equilibrium temperature of the α-γ change in the composition range 0 to 10% Ni was plotted. SE (10)

Statistical Studies of Structure (Statistische Gefügeuntersuchungen) E. Scheil. *Zeitschrift für Metallkunde,* Vol. 27, Sept. 1935, pages 199-209. With discussion. The already great usefulness of the metallurgical microscope can be increased and be made quantitative, rather than qualitative, by the application of statistical methods of analysis. An example of the integration method is the comparison of special samples with standard grain-size charts. Individual observations can also be made valuable by plotting a distribution curve for large numbers of them. Simple graphical methods for such studies are explained. Results already obtained from deformation measurements on individual crystals, as well as the relative deformation of slag inclusions and the effect of temperature upon this property are cited. A treatment is given of the determination of spatial grain size from two-dimensional observation of the number and size distribution of grains. This is based upon the assumption that the grains may be considered as spheres. Additional applications of statistical analysis to such problems as directional distribution of structural features, dendrite studies, dimensions of eutectic structures, and experimental confirmation of statistical theories are suggested. GD (10)

Study of Metallic Crystals (Sur l'étude des cristaux métalliques) E. SCHMID. *Revue de Métallurgie,* Vol. 32, Dec. 1935, pages 638-648. Summary of the present views on the nature and processes of deformation of single crystals. 28 references. JDG (10)

Thermal Expansion and Constitution of Antimony (Ueber thermische Ausdehnung und Konstitution des Antimons) A. SCHULZE. *Zeitschrift für Metallkunde,* Vol. 27, Dec. 1935, pages 286-287. A review of work on anisotropy of thermal expansion and electric conductivity of Sb and of the search for allotropic modifications of Sb, dealing chiefly with the investigations of P. Hidnert (*National Bureau of Standards, Journal of Research,* Vol. 14, No. 5, 1935, pages 523-544). It is concluded that Sb undergoes no allotropic transformation between room temperature and 600° C. FNR (10)

Studies of the Crystal Structure of Some Be Alloys (Kristallstrukturelle Untersuchungen von einigen Berylliumlegierungen) L. MISCH. *Metallwirtschaft,* Vol. 15, Feb. 14, 1936, pages 163-166. The following structures are determined: CoBe and PdBe are of the body-centered cubic CsCl type with $a_0 = 2.606$ and 2.813 A.U. respectively. $AgBe_2$ and $TiBe_2$ are of the face-centered cubic $MgCu_2$ type with $a_0 = 6.287$ and 6.435 A.U. respectively. $CrBe_2$, $MnBe_2$, VBe_2, $ReBe_2$, $MoBe_2$, and WBe_2 all occur with the hexagonal structure of the $MgZn_2$ type; the lattice constants and parameters were determined. With atomic ratios of about 1:2, Ir-Be and Rh-Be have similar complex structures with isotropic properties. Alloys of Be with Rh and Os have similar structures. Pt-Be form one compound, which is of a deformed γ-brass type. Zr-Be with an atomic ratio of 1:2 has a strongly isotropic lattice of a deformed cubic type. Be-rich alloys with Mo, W, and Ta form tetragonal lattices. Be-rich alloys with Co form a strongly isotropic phase similar to those with Fe. These structures are listed, along with previously determined crystallographic data for many Be alloys. It is observed that with the exception of CuBe, the Hume-Rothery rule is not obeyed for alloys of the cubic AB structure, and that the hexagonal AB_2 lattice occurs only when the cubic AB lattice is not found, i.e., when A is body-centered cubic. GD (10)

Effect of Decarburization on the Microstructure of Quenched High Speed Steels. TAKEJIRO MURAKAMI & ATSUYOSHI HATTA. *Tetsu to Hagane,* Vol. 21, Dec. 25, 1935, pages 993-997. In Japanese. In microstructure of high speed steel quenched from a high temperature such as 1300° C., troostitic structure often appears in its decarburized part. In order to elucidate the formation of the structure, a sectional diagram of 18% W and 4% Cr with varying C content was constructed by means of thermal analysis, differential dilatometric measurement and microscopic investigation. From the diagram obtained the change of microstructure of the high speed steels with different C content cooled from the melt was made clear. The troostitic structure also appears in the low C high speed steel cooled from the melt owing to the occurrence of a eutectoid reaction, $\gamma \rightarrow \alpha + \eta$, in the temperature range below 1340°. The formation of the similar troostitic structure observable in decarburized portion of quenched high speed steel is, therefore, attributed to the same reaction taking place during rapid cooling. TS (10)

Experimental Study of Heterogeneity of Metals and Alloys (Etude expérimentale de l'hétérogéneité des métaux et alliages) ALBERT PORTEVIN & PIERRE CHEVENARD. *Revue de Métallurgie,* Vol. 33, Feb. 1936, pages 96-113. Heterogeneity of metals can be caused by liquation phenomena, major segregation, and secondary liquation occurring on solidification and fusion or during allotropic transformation when the changes from one phase to another are not fully completed. Structural heterogeneity is caused by the orientation of crystals. Heterogeneity can be determined qualitatively by chemical means. Physical methods offer a better way of approach, such as determination of ferromagnetic curve, hardness measurements with a diamond point device, microtesting machine proposed by Chevenard, etc. Thermomagnetic curve obtained on specimens free from heterogeneity shifts from its original position when heterogeneity is produced, and the amount of this shifting permits determining the intensity of this phenomenon. Applied to carburized Ni-Cr alloys the method permitted establishing of secondary liquation in ingots as cast. As neither solution nor precipitation of particles takes place instantaneously, a concentration gradient builds around them until equilibrium is established. Thermal treatment and deformation influence on secondary liquation of Ni-Cr-C alloys were studied and reported. All show the existence of concentration heterogeneity in solid solutions, showing that the present theories should be augmented by the conception of it. For example, hardening produced by drawing specimens quenched from very high temperatures and observed before any visible precipitation takes place should be attributed to heterogeneity inevitably preceding precipitation rather than to atomic phenomena. JDG (10)

New Method for Determination of Transformation Points (Über eine neue Methode zur Bestimmung Umwandlungspunkten) H. NIPPER & E. LIPS. *Zeitschrift für Metallkunde,* Vol. 27, Oct. 1935, pages 242-243. Mechanical properties of metals are found to be more sensitive indicators of certain types of phase transformation than are the more commonly measured properties. This is particularly true at the solidus transformation where, upon heating, liquid is formed at the grain boundaries with a consequent sudden lowering of tensile strength. An apparatus has been constructed for applying a torsional load to a wire specimen the temperature of which may be controlled accurately. The torsional response is recorded automatically and a plot of stress vs. temperature obtained. As a test of the equipment, two points on the Cu-Ag solidus were located with precision far greater than could be obtained by thermal analysis. FNR (10)

Effect of Cold Deformation on the Behavior of an Austenitic Silico-manganese Steel During Tempering (Einfluss der Kaltverformung auf das Verhalten eines austenitischen Silizium-Mangan-Stahles beim Anlassen) F. BOLLENRATH. *Archiv für das Eisenhüttenwesen,* Vol. 9, Sept. 1935, pages 155-162. A 2% C, 1% Si, and 3% Mn steel was made austenitic by quenching, then cold worked and tempered. Dilatation-temperature curves on heating indicated that carbide separated out first, after which the γ-α change occurred. With increasing cold work the temperature ranges of these changes were lowered and narrowed. In severely deformed steel the γ-α change occurred more readily directly after, or even during, the precipitation of carbides; the precipitated carbides were also readily spheroidized. The greatest hardening took place during precipitation of the carbides rather than after the γ-α change as in unalloyed steels. After precipitation the hardness changed more with temperature than in austenitic steels. The greatest hardening was obtained after slight deformation. SE (10)

Metallurgical Dialogue. ALBERT SAUVEUR. American Society for Metals, Cleveland, 1935. Cloth, 5½ x 8¼ inches, 166 pages. Price $3.00.

This is a delightful book!

A modern student, by no means embarrassed in the presence of his august professor, asks a simple question, "Master, do we know why steel hardens when plunged red hot in cold water?" But the master asks in reply whether the pupil knows what steel is, what red hot means,—and we have as a result 166 pages of Socratic discussion of iron and steel: the historical development of theories, practice, nomenclature, in fact almost everything relating to the metallurgy of iron and steel. The pupil is acute and not restrained from making remarks verging on impertinence, nor from interrupting the master in his infinite peregrinations to ask whether the original question will *ever* be answered. But the master is good-humored, tolerant, and intellectually benign, favoring his pupil's intellectual appetite and impatience; he treats his pupil (and the reader) to as interesting a discussion of the important aspects of his subject as one might hope to find in lay language, not hesitating meanwhile to dissertate upon such diverse subjects as the futility of academic degrees, of course not of education, the vanities and conceits of scientists, the ideals of science (with the sophistication of the French), and—but the list is nearly endless. We may readily recognize the master—he is Professor Sauveur himself! And his former students may wonder with some trepidation about the identity of the saucy student!

The master is distrustful (cautious would probably be a better word) of speculation, and not over-impressed with the preeminence of modern accomplishments in comparison with those of earlier years; this is, of course, as it should be, but it is well to be reminded. The master loves true humility:

"M. He (Röntgen) called them X-rays because he did not know their nature.

"P. That was foxy of him. I wonder what he would have done, if there had not been a letter X in our alphabet?

"M. I admit that the letter X is a very useful letter and one that might be used more frequently by some scientists. As it implies an admission of ignorance, however, there are some who are—shall we say too proud?—to make use of it.

"P. That seems to me to be a false pride, unworthy of a true scientist. Conceit is a better name for it.

"M. I think as you do."

"M. You must do your own thinking and weigh the evidence offered.

"P. Some scientists do not like to have you disagree with them.

"M. That is true and this peculiarity is not confined to scientists. It is an unfortunate attitude which must interfere rather than help in their activities which should be the relentless pursuit of truth. It also diminishes our confidence in the accuracy of their conclusions and detracts from whatever personal attraction they may have.

"P. You are severe with the conceited man of science.

"M. This severity, I think, is justified. Let me urge you to avoid dogmatism and conceit."

We find the names long famous in metallurgy scattered through the book, Osmond, LeChatelier, Roberts-Austen, Percy, Arnold, Howe, and many others, with their portraits and with copious quotations from their writings which at times seem quite modern. It cannot be denied that their writings often were more sparkling than modern writing, in the cold matter-of-fact style now demanded of scientists. In speaking of recalescence, Howe said:

". . . by relatively rapid cooling we can carry the metal considerably below Ar, without giving the Ar_1 change time to proceed far, strengthening the while the tendency toward this change, which keeps kindling more and more till it bursts into a blaze, with such evolution of heat as actually to recalesce, to raise the temperature of the metal by some 10° C. in spite of the continued cooling of the furnace."

The discussion of early theories of the hardening of steel, and the old polemic centering about β iron are as fresh as though the arguments had been alive yesterday; however greatly the reader may feel driven to argue his own views, in this or other connections, he finds the master's detachment and mental adroitness more than his equal. It is amusing that the argument concerning the nature of the A_2 change in iron, once so violent, seems now to be revived in a somewhat similar form in the case of the changes which accompany super-lattice formation, for in this case also the application of the term "phase change" is beset with difficulties. We can only agree that definitions are devilishly awkward things in metallurgy as elsewhere.

One last quotation can hardly be resisted:

"Scientific honesty demands that you play havoc with the pet theories of your best friends, if they stand in your way, and if it is necessary in order to support your views—and our best friends should not in the least resent it. Let them reply in kind, if they have the ammunition. We are all traveling towards the same destination, although we may disagree as to the best road to follow and it is proper that we should place as many obstacles as we can in the path of those who, in our opinion, are following the wrong direction."

This independence of mind,—the humility, tolerance, and courtesy so much in evidence elsewhere, are qualities that all recognize in Professor Sauveur.

It must not be supposed that the book is for entertainment alone; it is a serious discussion of the science of iron and steel, put—for once—in a palatable and brief form. No metallurgist should fail to read it, nor to own it, for it is instinctive and delightful as well to the old and tried as to the young and uninitiate. Robert F. Mehl (10) -B-

Creep and Twinning in Zinc Single Crystals. RICHARD F. MILLER. *Metals Technology,* Apr. 1936, *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 703, 15 pages. Zn single crystals ½" in diameter and 10" long (purity 99.999%), grown by the Bridgman method, were subjected to creep tests. A modification of the 2-microscope extensometer was employed, each microscope having a triple lens system, a magnification of 125x, a working distance of 3", and an accuracy of 3.3 x 10^{-6} in./in. on a 6" gage length. Creep was found to obey the crystallographic laws of glide. Much creep occurred with resolved shearing stresses as low as 2.8 g./mm.^{2} at 25° C., confirming Taylor's theory. No evidence was found of an elastic limit, nor of a critical temperature below which a definite shearing stress might occur. Remarkable ductility was maintained at lower temperatures, the ductile crystals bending readily under their own weight at the temperature of liquid air. Twinning on a 2nd order pyramidal plane of variable index was noted to be a characteristic of the early stages of the flexural gliding process, partly accounting for the phenomenon of shear strengthening. In contrast to the absence of measurable critical stress for glide, there was a large threshold stress for twinning on $\{10\bar{1}2\}$, which varied inversely with the amount of preceding basal glide. This observation may explain the difficulty of previous investigators in obtaining a constant twinning stress in different crystals at any one temperature. 15 references. JLG (10)

11. PROPERTIES OF METALS AND ALLOYS

Mechanical-technical Properties of the Pure Metals (Die Mechanisch-technologischen Eigenschaften der reinen Metalle). A. Burkhardt with the collaboration of G. Sachs. First sub-section of the tenth section **(Mechanical-technical Metallurgy)** of the second part **(Physical Metallurgy)** of the second volume **(The Properties of Metals and their Alloys)** of **Metallography** edited by W. Guertler. Gebrüder Borntraeger, Berlin, 1935. Paper, 7 x 10¾ inches, 494 pages. Price 54RM.

This is the latest section (synonyms are much in demand for the description of the German method of subdividing handbooks) of Professor Guertler's famous *Metallographie*. The first volume, written by Prof. Guertler himself, appeared in 1912; since then additional volumes have appeared from time to time, now totalling 13. Metallography has developed so rapidly in this time—24 years—that the first and last volumes belong to different eras, and though the whole treatise is of unmistakable value, the long delay in accomplishing the full task has greatly diminished the usefulness of the work. There cannot be a "complete whole" here: one can hardly turn for information from the present volume on mechanical properties back to the first volume on the constitution of binary systems, published 24 years earlier, and obtain much satisfaction. Unless a comprehensive treatise of this sort appears complete within a reasonable time-period its effectiveness is largely lost.

These remarks should in no way detract from the admirable character of each of the separate volumes which have appeared. These volumes represent that pronounced German trait of completeness, of exhaustive bibliographic research so evident in the continual publication of important books,—a condition which makes the English-speaking metallurgist envious of the library facilities of his German colleague. Apart from the recent admirable effort of the Engineering Foundation in publishing the *Alloys of Iron Monographs* in this country, English publications on metallurgy have been sporadic and little given to meeting the needs of the trade or the profession.

The present book reflects the growing importance to the metallurgist of a knowledge of the elastic and mechanical properties of metals. Those happy days when a laboratory metallurgist needed only to be able to recognize alloy structures under the microscope, and to know only the elementary principles of heat-treatment, are unhappily past. The mechanical properties are obviously of first importance in determining fabricating procedure; metals and alloys are sold and used chiefly because of their mechanical properties (I have never heard of a sales manager ordering a thousand tons of martensite to conform in specifications to a photomicrograph!). This part of the science is growing rapidly and is now as important to the metallurgist as metallography in the old sense; it is surprising that the first serious attempt to organize this field was made as late as 1925 (G. Sachs. *Mechanische Technologie der Metalle*). In a rapidly growing science, the present volume, needless to say, is very welcome.

Burkhardt and Sachs have assembled from the literature pertinent information on the mechanical and technical properties of the pure metals. Each metal, with the exception of several groups like the platinum metals, is listed separately, with discussions of physical constants, degrees of purity (and, fortunately, sources of supply which as given are largely German), elastic constants, plastic behavior, and technical properties, including methods of melting, purification (only briefly), and fabrication. The data are given in a multitude of tables and diagrams, and photomicrographs are frequently used in illustration. True stress-strain diagrams are often used; X-ray photograms, and the prejudiced pole-figure and stereographic projection are presented to describe the plastic properties, particularly preferred orientations. Results on the study of single crystals are given when available, and the effect of grain size on physical properties described when possible; recovery and recrystallization phenomena are included.

It would be a difficult task to ascertain the completeness of the work,—an attempt was made to have it complete up to the beginning of the year 1934. Some lack of balance is evident: only 14 pages are devoted to Fe, whereas 16 are given to Ag and 63 to Zn! Kenyon's paper on Armco Fe is not included, nor is the work of Edwards and Pfeil on single crystals of Fe; I believe that Cioffi's work on pure Fe was reported in time for inclusion, though it does not appear. A more complete treatment of blue-brittleness and aging would be welcome, for all pure irons exhibit these phenomena. The sections on Cu, Al and Zn are very complete; much space is devoted to a discussion of the effect of impurities on the properties of Cu; space is often given to special topics pertaining to particular metals, such as hydrogen brittleness in Cu, desulphurization of Ni, and the allotropy of Fe.

This book is a valuable and needed addition to the metallurgical literature. So far as I know it is the only reference book available on the mechanical properties of the metals, and it can certainly be used to advantage by the metallurgist—if he will. The book will appear in better perspective when the comparison volume on the mechanical properties of alloys appears.

The Distribution of Molecules in a Model Liquid. W. E. Morrell & J. H. Hildebrand. *Journal of Chemical Physics,* Vol. 4, Mar. 1936, pages 224-227. By means of a 3-dimensional molecular assemblage the relative frequency of occurrence of the varying intermolecular distances of a liquid may be determined. The model simulates the expansive effect of temperature and by it a good approximation is obtained to the distribution of molecules in liquid mercury determined by Menke with X-ray diffraction methods. FPP (11)

On the "Permalloy Problem." J. L. Snoek. *Nature,* Vol. 137, Mar. 21, 1936, page 493. Studies on permeability by Lichtenberger, Dillinger and Bozorth, Yensen and Ziegler, and Ruder, may be correlated with Lichtenberger's theory for the high permeability of permalloy (78% Ni). Disturbing effects from magnetostriction and crystal anisotropy are a minimum at the permalloy composition. CSB (11)

Powder Metallurgy, Notes on the New Art. Charles Hardy. *Metal Progress,* Vol. 29, Apr. 1936, pages 63-67. Describes the growth and applications of powder metallurgy from its origin with metals too refractory for melting to the preparation of very high purity alloys with new possibilities and properties. WLC (11)

11a. Non-Ferrous

A. J. PHILLIPS, SECTION EDITOR

Niobium and Its Uses. L. Sanderson. *Sands, Clays & Minerals,* Vol. 2, Apr. 1936, pages 99-101. Cb, one of the rarer elements, is contained in columbite which is an end member of a series of niobates of Fe and Mn; [illegible] closely resembles Ta and melts above 1800° C. It is mainly used as electrode material in radio valves and as a "getter" in vacuum tubes; it has a larger electron emission than Mo at high temperatures. When used as alloying element in steel it is said to render the metal harder and tougher than other elements, and it acts also as scavenger, in a manner similar to V. The metal is produced by reduction from the ore and manufactured into bars, sheets, wires and rods, but very little has been produced. The principal compounds are CbH, CbO_2, Cb_2O_4, Cb_2O_3, Cb_2O_5 and CbF_5KF. Sp. gr. is 8.3. As a stabilizer of stainless steels, it retards intergranular corrosion, especially after long holding at 1000°-1500° F. Ha (11a)

Magnetochemistry of Rhenium (Sur la Magnéto-Chimie du Rhenium) Nicolas Perakis & Léandre Capatos. *Journal de Physique et le Radium,* Series 7, Vol. 6, Nov. 1935, pages 462-468. Metallic and heptavalent Re were each found to possess very feeble paramagnetism, independent of the temperature within the interval — 190° to + 25° C. The coefficient of susceptibility was found to be + .366 x 10^{-6}. FPP (11a)

Relative Rates of Diffusion of Hydrogen and Deuterium Through Heated Platinum (Etude Comparative des Vitesses de Diffusion de l'Hydrogène et du Deutérium a travers le Platine Chauffé) René Jouan. *Journal de Physique et le Radium,* Series 7, Vol. 7, Feb. 1936, pages 101-106. The rate of diffusion of deuterium through Pt heated to various temperatures between 450° and 950° C. was ¾ that of H, a difference so slight as to preclude use of such a process for separating a mixture of the isotopes into its constituents. FPP (11a)

Influence of Phosphorus and Sulphur Upon the Mechanical Properties of Platinum and Palladium (Der Einfluss von Phosphor und Schwefel auf die mechanischtechnologischen Eigenschaften von Platin und Palladium) A. Jedele. *Zeitschrift für Metallkunde,* Vol. 27, Dec. 1935, pages 271-275. The embrittlement of Pt and Pd by small additions of P and of Pd by S is verified while Pt is found to be little affected by S up to 0.15%. The systems Pt-P, Pd-P and Pd-S form low melting grain boundary constituents (Pt — Pt_7P_{20} eutectic melting at 588° C.; solid solubility 0.005% P) (Pd-P low melting eutectic; solid solubility about 0.01% P) (Pd_4S melting at 761° C.; solid solubility about 0.01% S) which are molten at ordinary hot working temperatures and cause hot shortness when the P or S is present in quantities greater than about half the limit of solid solubility. S dissolves in Pt at least up to 0.23% and increases the hardness but not the hot shortness within the range noted above. The ultimate strength (t.s.) in kg mm.², yield point, elongation (E) in %, and Brinell harness (BHN) of the following composition ranges were measured on rolled and drawn stock at room temperature:

Temp.	Composition range	Ten. str. range	Elong. range	Composition	B.H.N. range
Room	Pt-P .001-.96	14.8-25.9	27.1-2.75	.001-.96	45-145
Room	Pd-P .006-.265	22.4-28.2	23.1-19.5	.006-.93	60-135
Room	Pt-S .005-.15	15.3-19.9	24.7-14.7	.005-.23	45-93
Room	Pd-S .001-.32	19.4-29.5	24.2-17.2	.001-.92	50-90
850° C.	Pt-P .001-.003	6.9-4.2	9-6.2		
850° C.	Pd-P .001-.006	5.3-4.1	9.2-15.2		
850° C.	Pt-S .005-.15	5.3-8.7	14.5-5.8		
850° C.	Pd-S .001-.003	6.6-8.1	16.8-18.8		

FNR (11a)

Ferromagnetic Increase of Resistance of the Copper-Nickel Alloys (Ferromagnetische Widerstandserhöhung der Kupfer-Nickel-Legierungen) B. Svensson. *Annalen der Physik,* Series 5, Vol. 25, Feb. 1936, pages 263-271. The specific electric resistance of 9 different Cu-Ni alloys was measured between 0°-500° C. and a formula developed giving the ferromagnetic resistance as function of concentration. 11 references. Heat Emission of Polonium; Determination of Its Radioactive Constants by Calorimetric Methods (Le Débit de Chaleur du Polonium; Determination par Voie Calorimetrique de ses Constantes Radioactives) A. Saniélevici. *Journal de Physique et le Radium,* Series 7, Vol. 6, Feb. 1935, pages 73-77. Using an adiabatic microcalorimeter, measurement was made of the heat emitted during radioactive emanation of Po. FPP (11a)

Zirconium and Its Compounds. L. Sanderson. *Chemical Trade Journal & Chemical Engineer,* Vol. 97, July 26, 1935, page 75. See *Metals & Alloys,* Vol. 6, Oct. 1935, page MA 411L/5. MS (11a)

The Plastic Deformation of Cadmium Single-Crystals. R. Roscoe. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Vol. 21, Feb. 1936, pages 399-406. Bending of monocrystal wires of Cd showed that, when the stress over the glide planes of a crystal is not uniform, slip begins when the max. value of the resolved shear stress reaches the critical value for deformation under uniform stresses. Surface oxidation of Cd monocrystals produces an increase in their resistance to plastic deformation which cannot be due to the cohesion of the oxide film; the added strength may be due to healing of submicroscopic cracks by the film. Ha (11a)

FORTIFY PERFORMANCE WITH THE RESPONSIVENESS OF FORGINGS–

WITH FLEXIBILITY

The dependable responsiveness of forgings to shocks, twists, and strains is inherent in millions of fibers of steel . . . fibers formed and compacted by rolling and hammering (directional working) the steel.

BE certain about flexibility. In forgings, flexibility is a controllable quality. Forgings impart the exact degree of flexibility required at the point where it is needed. Yielding to shocks and pressures and recovering demonstrates the flexibility of forged parts. Within the dense structure of kneaded fibers of steel, an exclusive characteristic of forgings—flexibility is merged with strength, toughness, stamina. Developed only by the forging process, these kneaded fibers of steel embody a resilience which reacts to the force of deforming shocks and endures relentless performance. Use forgings to control flexibility. Invite the counsel of competent forging engineers. Write for booklet.

DROP FORGINGS ARE THE SINEWS OF COUNTLESS USEFUL THINGS

OFHC
REG. U.S. PAT. OFF.

OXYGEN-FREE HIGH CONDUCTIVITY

A Superior Copper for All Purposes

OFHC Copper conforms to the A.S.T.M. Specification for electrolytic copper wirebars, cakes, etc., B5-27 with regard to metal content and resistivity, and is free from cuprous oxide.

OFHC Copper is characterized by its freedom from casting defects and its bar-for-bar uniformity. Its freedom from oxygen results in great ductility and toughness as evidenced by its high reduction of area and resistance to impact.

OFHC Copper withstands more working in hard condition when tensile strength is greatest, making it especially suited for products subjected to severe fabricating or service conditions.

Copies of a schedule of weights and dimensions of **OFHC** wirebars, cakes and billets, and a booklet containing technical information will be gladly furnished upon request.

Subsidiary of The American Metal Co. Ltd.
61 Broadway, New York, N. Y.

Silumin. Metallgesellschaft, Frankfurt-am-Main, 1936. Paper, 8 x 12 inches, 56 pages.

Modified cast Al-Si alloys, first introduced by Dr. Pacz under the trademark "Alpax," are known in Germany as "Silumin." The basic alloy contains about 13% Si, but modifications containing small amounts of Cu and Mn are known as copper-Silumin, and alloys containing added Mg and Mn are known as Silumin-beta and Silumin-gamma. This booklet gives a summary of the physical and mechanical properties of these alloys, together with suggestions regarding casting, heat treatment, working and surface finishing. The book is attractively illustrated with photomicrographs, diagrams, art studies of casting and testing operations, together with a multitude of photographs of various articles formed from these alloys. J. D. Edwards (11a) -B-

Experiments on the Electrical Resistance of Copper and Some Copper Alloy Wires. C. Blazey. *Engineering,* Vol. 141, Mar. 20, 1936, page 320. Abstract of paper read before the Institute of Metals. See *Metals & Alloys,* Vol. 7, May 1936, page MA 257L/1. VSP (11a)

Non-Ferrous Alloys Available for the Use of Industry. High Tensile Bronzes and Brasses. *Aluminium & the Non-Ferrous Review,* Vol. 1, Apr. 1936, page 300. Lists characteristics of Immadium II, III, IV, V, and VI, Crotorite IV and V, and Aluminium Bronzes Nos. 135 and 136, made by Manganese Bronze and Brass Co. JCC (11a)

Large Single Crystals of Cooper. Simplified Method for Their Preparation. J. G. Thompson. *Metals & Alloys,* Vol. 7, Jan. 1936, pages 19-21. 3 references. Describes preparation of single crystal of Cu large enough to machine into a 2.25" sphere by melting in a vertical Arsem furnace and slowly cooling the mass in the melting crucible from the bottom upward. WLC (11a)

Magnesium Silicide in 85-15 Brass. Effect on the Properties. H. S. van Klooster & J. E. Harris, Jr. *Metals & Alloys,* Vol. 7, May 1936, pages 135-139. Additions of up to 4.7% Mg_2Si to 85-15 brass shows increased hardness and decreased electrical conductivity with high Mg_2Si. Annealing tends to increase both properties up to about 500° C. No age hardening is observed. Hard particles of Mg_2Si scattered through the brass after prolonged annealing at high temperatures produce a structure of possible application as bearing metal. 8 references. WLC (11a)

Effect of Thallium on the Freezing Point of Indium-Lipowitz Alloy. Sidney French. *Metals & Alloys,* Vol. 7, Mar. 1936, page 64. Alloy of 81.9% Lipowitz metal and 18.1% In (m.p. 46.5° C.) was not reduced in m.p. by Tl additions but the sharpness of m.p. was reduced. WLC (11a)

The Effect of Thallium on the Freezing Point of Lipowitz Alloy. Sidney J. French & Donald Saunders. *Metals & Alloys,* Vol. 7, Jan. 1936, pages 22-23. 6% Tl produces alloy freezing at 66.6° C. or 3.1° C. lower than Lipowitz alloy. WLC (11a)

Elektron and Hydronalium Castings (Ueber Elektron- und Hydronaliumguss) P. Spitaler. *Giesserei,* Vol. 23, Apr. 10, 1936, pages 177-181. Certain conditions which should be observed when casting elektron metal (Mg alloy with Al) and hydronalium (Al alloy with 3-12% Mg) are discussed and explained. Al-containing Mg alloys obtain a much finer structure if the melt is overheated (to about 900° C.) which also influences castability and mechanical properties favorably. A certain manner of filling the mold is described which secures the dense structure. Hydronalium melts have a tendency to strong oxidation and formation of nitrides and dissolve H; by adding boric acid this tendency is largely reduced. Tables of mechanical properties for different compositions of both alloys are given. Ha (11a)

The Effect of Heat Treatment on the Structure of Gold- and Silver-Leaf. G. D. Preston & L. L. Bircumshaw. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Vol. 21, Apr. 1936, pages 713-727. Au and Ag leaves were heated in air, H and in vacuum and tested by the electron diffraction method with regard to eventual changes. A contraction takes place when Au leaf is heated in air to about 350° C. whereby recrystallization and reorientation of the crystals take place. These changes are absent in H at even higher temperatures and in vacuum. Similar effects are observed in Ag leaf but at lower temperatures. 10 references. Ha (11a)

Selection of Light Alloys for Aero Engines. J. R. Handforth. *Metal Treatment,* Vol. 2, Spring 1936, pages 3-13. This paper is remarkable for its comprehensive tables. Details are given of compositions and mechanical properties of all the principal American, British, and German wrought and cast Al alloys. In addition, the alloys chosen by 10 leading manufacturers for the principal nonferrous components of their aero engines are tabulated. Mg alloys are little used. Besides mechanical properties, it is often necessary when making a choice of alloy to consider such characteristics as anti-frictional properties at high temperatures, specific heat, thermal conductivity, and coefficient of thermal expansion. JCC (11a)

Production of White Metal Linings. Edmund R. Thews. *Canadian Chemistry & Metallurgy,* Vol. 20, Apr. 1936, pages 111-112. The strength, ductility, and frictional properties of the white metal liners are of no greater value than the adherence and compression strength. In applying a lining, a number of important points must be considered: the properties of the alloy used, composition and size of the bushings, the diameter of the shaft or journal, finish on the inside of the bushings, temperature of the bushing, the pouring temperature of the white metal and temperature of the shaft or journal, metal to metal adhesion, cleaning and etching, tinning the bearing, lining temperature, the effect of rate of cooling, and core conditions are discussed. The essential conditions in lining bearings with white metal are summarized as: (1) correct composition of the lining material, (2) proper preparation of the bearing surface, (3) correct cleaning and etching, (4) correct tinning, (5) rapid succession of etching, tinning and lining, (6) proper bearing and lining temperatures, (7) correct temperature of journal core, and (8) avoidance of vibration during cooling of lining. WHB (11a)

Photoelectric Effect of Aluminum Films Evaporated in Vacuum. E. Gaviola & John Strong. *Physical Review,* Vol. 49, Mar. 1936, pages 441-443. Sensitivity curves of Al films deposited by evaporation in vacuum have been determined. A new threshold value of 2830 A.U. and a selective maximum around 2700 A.U. have been found. The cell has the form of a horn, absorbing all the incident light. Charcoal was used for producing high vacuum and for giving off gases that influence the position and inclination of the sensitivity curves. WAT (11a)

Inconel (Inconel). R. Hanel. *Chemische Fabrik,* Vol. 9, May 13, 1936, pages 217-220. Chemical composition, physical and mechanical properties, corrosion resistance, heat resistance, workability hot and cold, foundry properties, heat treatment, surface finishing, welding, soldering and applications of Inconel are discussed and tabulated. The alloy contains 80% Ni, 14% Cr and 6% Fe, is resistant to many corrosive fluids, resists oxidation to 1100° C., is less susceptible to high temperature sulphur attack than Ni, and is used as castings, sheet, tubing, bars and rods. FPP (11a)

Endurance Limit of Aluminum Alloys (Limite d'endurance des alliages d'aluminium) R. Irmann. *Revue de Métallurgie,* Vol. 33, Apr. 1936, pages 231-236. A general discussion. JDG (11a)

Atomic Weight of Gallium. G. E. F. Lundell & James I. Hoffman. *Bureau of Standards Journal of Research,* Vol. 15, Oct. 1935, pages 409-420. Preliminary tests showed that the metal was free from an appreciable film of oxide and did not contain occluded gases. The highly ignited oxide, obtained through the hydroxide or the sulphate, contained no gases and was not appreciably hygroscopic. The oxide obtained by igniting the nitrate was less satisfactory. To make possible the correction of the weights to the vacuum standard, the density of the oxide was also determined, and found to be 5.9 g./cm³. The value for the atomic weight based on this work is 69.74. WAT (11a)

Electrical Conductivity of Thin Films of Rubidium on Glass Surfaces. A. C. B. Lovell. *Nature,* Vol. 137, Mar. 21, 1936, pages 493-494. The conductivity of layers of Rb 1 to 10 atoms thick has been measured. Conductivity first becomes appreciable, with conditions of high purity and high vacuum in layers of ½ atom average thickness. CSB (11a)

Permeability of Pd to H_2. Effect of Temperature on Diffusion in Pure Pd. Regeneration of Contaminated Pd (Perméabilité du Palladium à l'Hydrogène. Perte du Pouvoir Diffusant du Palladium Pur sous l'Action de la Température. Régénération du Palladium Empoisonné) Victor Lombard, Charles Eichner & Maxine Albert. *Comptes Rendus,* Vol. 202, May 25, 1936, pages 1777-1779. Prolonged heating of Pd in H_2 at 500°-520° C. gives maximum penetration. Reheating in air at 500° C. with a subsequent heating in H_2 below 140° C. to reduce the superficial layer of oxide formed will restore the Pd to its original state. FHC (11a)

Photoelectric Effect of Pd-Ag Alloys Saturated with Hydrogen (Lichtelektrische Empfindlichkeit von Palladium-Silberlegierungen, die mit Wasserstoff gesättigt sind) F. Kruger & W. Kallenboch. *Zeitschrift für Physik,* Vol. 99, Apr. 14, 1936, pages 743-750. After 30 hrs. in H_2, an alloy with 20% Ag shows a maximum photoelectric effect and an alloy of 60-65% Ag the minimum effect. FHC (11a)

The Longitudinal Thermoelectric Effect: (6) Mercury. J. L. CH'EN & W. BAND. *Proceedings, Physical Society,* Vol. 48, Jan. 1936, pages 164-167. It is confirmed that the Benedicks e.m.f. in Hg contained in an unrestricted glass tube falls off with rise in temperature and is restored on cooling. It seems plausible to explain this by assuming that anisotropic liquid crystals exist in the liquid, their arrangement depending on temperature. JCC (11a)

Beryllium and Beryllium Alloys. M. G. CORSON & J. D. ZEISER. *Iron Age,* Vol. 137, Mar. 5, 1936, pages 28-32, 74. Reviews the history of Be, and the various alloys of Be are considered both from the technical and practical standpoint. The different properties of the alloys are listed and attention is focused on characteristics fitting the various alloys to specific industrial applications. Proper foundry practice is discussed in detail. Includes a table showing the characteristics of Ni-Be alloys of 1.7% Be. VSP (11a)

Study of Thermionic Emission of Salts Through Copper (Étude des Conditions de l'Emission Thermionique de Sels Diffusant a travers le Cuivre) J. CICHOCKI. *Journal de Physique et le Radium,* Series 7, Vol. 6, Sept. 1935, pages 397-400. Investigation of the thermionic emission of Cu sheet filled with alkaline halides revealed variations in work function explainable only by assuming the existence on the surface of the electrode of a monomolecular layer of alkali-metal atoms that had diffused through the Cu and combined with the Cu or its oxide. FPP (11a)

Skin Deep: Allowable Stresses in Stressed-skin Structures. JOSEPH S. NEWELL. *Aviation,* Vol. 34, Dec. 1935, pages 18-20. Based on Bureau of Standards Tests, formulae for calculating the maximum load carried by 17ST Aluminum Alloy flat sheets with V-groove edge supports are plotted and compared. FPP (11a)

Thermionic Electron Emission. J. A. BECKER. *Bell System Technical Journal,* Vol. 14, July 1935, pages 413-476. Comprehensive theoretical review which while mostly mathematical physics, contains information bearing on metallurgy of filament wire. Various crystals of a filament wire have different work functions and electronic emission. A compiled table giving values of the photoelectric and thermionic heat functions of many pure metals is given. HFK (11a)

Making and Testing Single Crystals of Lead. B. B. BETTY. *Proceedings American Society for Testing Materials,* Vol. 35, Part II, 1935, pages 193-203. Includes discussion. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 145L/1. (11a)

Non-Ferrous Nickel Alloys. L. M. ANGUS-BUTTERWORTH. *Engineer,* Vol. 161, Feb. 28, 1936, page 224. Brief article outlining the effect of heat treating on the properties of certain non-ferrous Ni alloys. By various heat-treating methods the alloys can be made either soft and ductile or hard and strong with high elastic properties. Heat treatment consists of softening by cooling rapidly from temperatures above 800° C. and hardening by reheating between 400° C. and 650° C. With the proper composition it is possible with one heating to obtain the combined effects of cold work, a strain-relief annealing and a hardening treatment. LFM (11a)

The Magnetic Transformation Point of Heavily Cold-worked Nickel. H. QUINNEY. *Journal Institute of Metals,* Vol. 55, No. 2, 1934, pages 229-245. Includes discussion. See "Some Properties of Heavily Cold-worked Nickel," *Metals & Alloys,* Vol. 5, Nov. 1934, page MA 535. (11a)

Plant-construction Materials. F. E. CARTER. *Chemical Trade Journal & Chemical Engineer,* Vol. 97, Aug. 16, 1935, page 140. See "Precious Metals as Materials of Construction," *Metals & Alloys,* Vol. 6, Oct. 1935, page MA 411R/9. MS (11a)

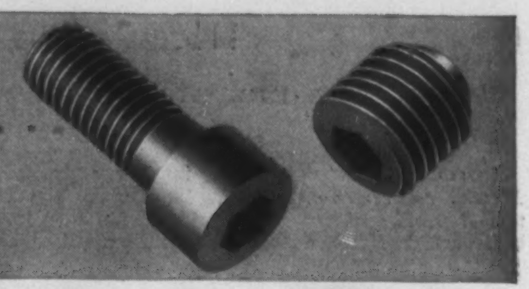
Non-ferrous Metals Handbook. Light Metals (Werkstoffhandbuch Nichteisenmetalle. Leichtmetalle, abschnitte G-K) Edited by G. MASING, W. WUNDER & H. GROECK. VDI Verlag, Berlin, 1936. Paper, 5½ x 8¼ inches, 174 pages. Price 13.50 RM.

Just as is the case with the "National Metals Handbook" of the A.S.M. the German handbooks are constantly being re-written and brought up to date. The Germans put the ferrous and non-ferrous data in separate handbooks. Their non-ferrous one is now out of print, and is being entirely re-written. All of the new edition is expected to be out during 1936 and 1937. The first section to be distributed is that on light metals. Most of the subsections in that section of the last edition were prepared in 1927. The 1936 edition of this section is some 25% larger. The heat-treatable alloys in particular are given more space than previously. Instead, as was often the case previously, of using German trade names as headings, those trade names, which have now become legion, are relegated to brackets below the main headings. The main divisions are pure Al, wrought alloys, cast alloys, and Mg and its alloys. The information is given in highly condensed form, with a selected bibliography after each subsection. With rare exceptions, the references are to German publications. It will be indispensable to German metallurgists, but the English-speaking reader, who will easily find the information he is after when only sketchy data are wanted, will have difficulty in chasing down the details when more comprehensive information is sought. H. W. Gillett (11a) -B-

Physical Properties of Babbitt, Tin Base Bearing Alloys. OWEN W. ELLIS. *Metal Progress,* Vol. 29, Feb. 1936, pages 56-59. Discusses the effects of various additions such as Zn, Al, Bi, Pb and Cd on various properties of Babbitt metal (Sn-Sb-Cu). Wear, fatigue, hot strength and hardness tests indicate that Cd improves these properties up to 1% Cd. WLC (11a)

The Physical Properties and Annealing Characteristics of Standard Nickel-Silver Alloys. MAURICE COOK. *Engineering,* Vol. 141, Mar. 20, 1936, page 320. Abstract of paper read before the Institute of Metals. See *Metals & Alloys,* Vol. 7, May 1936, page MA 258R/1. VSP (11a)

The Thermomagnetic Properties of Nickel. Part 2. WILLIAM BAND & Y. K. HSÜ. *Proceedings, Physical Society,* Vol. 48, Jan. 1936, pages 168-177. Determinations of the homogeneous thermoelectric e.m.f. in a Ni wire 1 mm. in diameter for various tensions up to 8 kg. are recorded and analyzed. It is suggested that the effect is controlled by the regularity of the arrangement of microcrystals within the wire. JCC (11a)



ALLOY STEELS

are economical steels to use where service conditions are unusually severe—calling for extreme toughness, hardness or wear resistance. The above screw parts, made of B & L Alloy Steel, annealed to proper structure and cold drawn, are meeting requirements far better than former grades used. Ask for details.

CHACE THERMOSTATIC BIMETAL USED IN THE Stimpson AUTOMATIC COMPUTING SCALE

In the manufacture of automatic counter computing scales, it is essential that the best thermostatic bimetal obtainable be used in the thermostatic control which mechanism accurately counteracts the expansion and contraction of the springs caused by changes in temperature. Chace Thermostatic Bimetal meets the requirements of both quality and dependability necessary in the manufacture of Stimpson De Luxe "Quality Supreme" Scales.

CHACE THERMOSTATIC BIMETAL
"It Bends with the Heat"

Manufacturers whose products demand automatic movement at predetermined temperature (heat or cold) will find Chace Thermostatic Bimetal a most dependable and economical servant.

V. V. KENDALL, SECTION EDITOR

Oxygen and Oxides Segregate in Reverse to Sulphur. ALBERT PORTEVIN. *Metal Progress,* Vol. 29, Mar. 1936, pages 65-66. Reports studies of segregation of O_2 in steel and suggests that, unless the location of the sample taken for O_2 analysis is known, erroneous conclusions may be drawn. WLC (11b)

Grain-Size and Its Influence on Surface Decarburization of Steel. D. H. ROWLAND & CLAIR UPTHEGROVE. *Transactions American Society for Metals,* Vol. 24, Mar. 1936, pages 96-132. Report of study of decarburization of C steels of 0.71-1.07% C. Data indicate that coarse grain steels lose more C than fine-grained under the same conditions. Time and temperature effects on character and depth of totally decarburized zone for both types of steel are reported. Relative widths of ferrite bands on coarse and fine grained steels are independent of time. Maximum depth of carburization at A_3 point of steels investigated is reported. Data are submitted in support of the theory that columnarization of ferrite between 1290°-1650° F. results from γ to α phase change. A theory is advanced for columnarization below A_1 point. Explanation of the mechanism of decarburization is reached from study of gas analysis of products of decarburization. 15 references. WLC (11b)

Choosing a Composition for Low-alloy High-strength Steel. S. EPSTEIN, J. H. NEAD & J. W. HALLEY. *Metals Technology,* Apr. 1936, *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 697, 31 pages. Steels were studied with the object of finding a composition that would give a yield strength of about 60,000 lbs./in.^{2}, a tensile strength of 75,000 lbs./in.^{2}, good ductility, formability approaching that of a C steel, and good weldability. The steel should have these properties in the as-rolled condition and should not require any special heat treatment. The literature is reviewed and summarized with reference to the effects of C, Mn, Si, Ni, Cr, Cu and P on the properties. The chosen composition was 0.10% max. C, 0.50% Mn, 0.12% P, 0.13% Si, 0.47% Ni, and 1.05% Cu. It was found that Cu, Ni and P increase yield strength more rapidly than tensile strength, whereas the other alloying elements increase tensile strength more rapidly than yield strength. Yield strength is considered of major importance in design. Tensile properties, bending properties, impact, hardness and weldability of the steel of the chosen composition are reported. Tensile and impact tests were made on welded specimens. 32 references. JLG (11b)

Some Alloys of Copper and Iron. The Tensile, Electrical and Corrosion Properties. EARLE E. SCHUMACHER & ALEXANDER G. SOUDEN. *Metals & Alloys,* Vol. 7, Apr. 1936, pages 95-101. Study of electrical and mechanical properties of 75%-37.5% Cu-Fe alloys shows little segregation in ¾" and 1" bars cast 20" long. All compositions hot worked satisfactorily from this size to 0.25" rod. Optimum combination of electrical and mechanical properties is found in 50-50 alloy aged at 500° C. before hard drawing which shows in 18 AWG a tensile strength of 180,000-190,000 lbs./in.^{2} and a conductivity 30% that of pure Cu. 19 references. WLC (11b)

Alloys of Copper and Iron. K. M. SIMPSON & R. T. BANISTER. *Metals & Alloys,* Vol. 7, Apr. 1936, pages 88-94. Reports study of hot and cold working properties of 25 and 50% Cu alloys of Fe. Physical property values are reported and it is stated that the alloys can be produced in wire, sheet, rod and seamless tubing. Effects of C and Cr on separation of 2 liquid phases and effects of Ni and Cr on corrosion resistance are discussed. In production of castings of ingots of the alloys proper feeding must be provided to take care of the large solidification shrinkage. 8 references. WLC (11b)

Note on Annealing Twins in Ferrite. ALLAN L. TARR. *Metals & Alloys,* Vol. 7, May 1936, page 130. Shows micrographs of annealing twins in Armco iron. WLC (11b)

The Role of Copper in Wrought Steel. CLYDE E. WILLIAMS & CLARENCE H. LORIG. *Metals & Alloys,* Vol. 7, Mar. 1936, pages 57-63. Cu increases yield strength with greater effect than C with less loss of toughness. Significant table shows the following in 3 steels having tensile strength of 100,000 lbs./in.^{2} in a normalized condition:

C content	0.47%	0.33%	0.20%
Cu content	0.00	1.00%	2.00%
Yield strength lbs./in.^{2}	60,000	67,000	80,000
Red. of area %	47	54	61
Elong. in 2 in. %	26	28	28
Brinell hardness	188	195	196

WLC (11b)

A Dilatometric Study of the Alpha-Gamma Transformation in High Purity Iron. C. WELLS, R. A. ACKLEY & R. F. MEHL. *Transactions American Society for Metals,* Vol. 24, Mar. 1936, pages 46-74. Paper and discussion from Chicago Convention of the Society, 1935. Fe used was prepared from selected Armco and carbonyl Fe by prolonged treatment in H_2 at high temperatures (1200°-1500° C.) for from 47-500 hrs. Vacuum-melted electrolytic Fe also studied. Chemical and spectroscopic analyses show high purity for carbonyl Fe. Dilatometric and thermal curves show agreement. Purest Fe samples show Ac_3 point independent of rate of heating and inferior purity samples show dependence upon rate. Rates of ⅛, ½ and 2° C./min. were used. 16 references. WLC (11b)

Martensite and Austenite in Hardened Steels. Their Transformation Temperatures. BENGT KJERRMAN. *Metals & Alloys,* Vol. 7, May 1936, pages 127-129. Reports measurements of electrical resistance of quenched steel while being tempered which indicate that tetragonal martensite can be transformed to cubic form at temperatures as low as 40° C. Austenite does not appear to begin to decompose until all the martensite has changed but starts at about 180° C. and is complete at 240° C. when long times are employed. See also *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 74R/9. WLC (11b)

Basic Electric Steel from "Masa" Magnetic Sand. TOYOZO ISHIGAKI. *Suiyokwai-shi,* Vol. 8, Mar. 30, 1936, pages 957-990. The "Kokusan-Kogyo" Co. (Domestic Industrial Co.) is producing basic electric steel from "masa" magnetic sand (pure magnetic sand) of Izumo and Hoki districts in Japan. The manufacturing process is unique to the Japanese. The steel produced by this method not only has good mechanical properties but also does not give rise to abnormal structure when carburized. The specimens of these specially produced steels and other steels from ordinary processes were chemically analyzed, especially for their O contents according to the Petersen process. The impact values of the specimens were also determined after suitable heat treatment. The impact value varies considerably among specimens manufactured by different processes. A careful examination of the relation between the impact value and the chemical composition leads to the conclusion that, C content in all the specimens remaining constant, the largest impact value was manifested by the basic electric steel only from "masa" magnetic sand and the value decreased in the order of basic electric steel from the mixture of the "masa" magnetic sand and steel scrap, Swedish acid open-hearth steel, and basic open-hearth steel, and it is due to their progressively increasing O content. HN (11b)

On the Elastic Constants of Single Crystals of Iron. REN'ITI KIMURA & KAICHI OHNO. *Kinzoku no Kenkyu,* Vol. 13, Mar. 1936, pages 99-102. In Japanese. From Young's modulus of elasticity E and the modulus of torsion n in various directions, the Voigt moduli were found for monocrystal Fe at room temperature. The results are as follows: $S_{11}.10^{12} = 0.765$, $S_{12}.10^{12} = -0.289$, $S_{44}.10^{12} = 0.895$; $E_{[111]} : E_{[100]} = 2.06$, $n_{[111]} : n_{[100]} = 1/1.90$. These values are all given in c. g. s. units. KT (11b)

Measurement of Specific Heat of Iron at High Temperatures (Die Messung der spezifischen Wärme von Eisen bei hohen Temperaturen) K. MELISS. *Archiv für das Eisenhüttenwesen,* Vol. 9, Oct. 1935, pages 209-212. The specific heat of Fe with 0.06% C was determined in a water calorimeter by the method of mixtures. A method is described for correcting for heat losses of the specimen on transferring from the furnace; the magnitude of the experimental errors was within 0.1%; the precision within 0.05%. The heat content of Fe over the temperature range 600° C. to 1250° C. is shown in a curve. SE (11b)

Tensile Properties and Corrodibility of High-Tensile Steels (Festigkeitseigenschaften und Korrosionsverhalten von Hochbaustählen) E. MAURER & H. HEINE. *Archiv für das Eisenhüttenwesen,* Vol. 9, Jan. 1936, pages 347-357. Tension and fatigue tests of various high-tensile German and American structural steels were made of smooth and notched bars, in air and under water, and after weathering, aging, and hardening. No significant differences were found between the steels, nor between those made with scrap-C practice and pig Fe-scrap practice. SE (11b)

Correlation of Failures from Embrittlement of 4-6 Per Cent Chromium Steel with Notched Bar Impact Test. H. M. WILTEN. *Transactions American Society for Metals,* Vol. 23, Dec. 1935, pages 915-967. 15 references. Discussion containing 25 additional references. Addition of 0.50% Mo to this steel prevents embrittlement as shown by both laboratory and service results. Similar data are covered in abstract of Low Alloy steel for Oil Refinery Service, R. L. Wilson, *Metal Progress,* Vol. 28, Sept. 1935, pages 29-33 (see *Metals & Alloys,* Vol. 7, Apr. 1936, page MA 204R/1). WLC (11b)

Properties of the 9% Chromium Steel (an intermediate alloy). H. D. NEWELL. *Metal Progress,* Vol. 29, Feb. 1936, pages 51-55. Describes development of 9% Cr, 1.50% Mo steel for moderately severe corrosive and oxidizing service up to about 1250° F. The composition specified is C 0.15% max., Mn 0.50%, max., Si 0.50% max., Cr 8.0-10.0%, Mo 1.25-1.75%. Tubes of this alloy will show physical properties over 75,000 lbs./in.^{2} tensile strength, 30,000 lbs./in.^{2} yield point, 30% elongation in 2 in. and Brinell of 180 max. Creep properties are reported as follows:

	900° F.	1000° F.	1100° F.	1200° F.
	lbs./in.^{2}	lbs./in.^{2}	lbs./in.^{2}	lbs./in.^{2}
0.10% in 1000 hrs.	33,250	11,650	6,950	2,300
0.01% in 1000 hrs.	24,750	5,800	3,775	1,600

WLC (11b)

Stainless Steels. H. BULL. *Aircraft Engineering,* Vol. 8, Feb. 1936, pages 51-54. A survey of the development of straight Cr and 18-8 steels. Weld decay is discussed and micros of failures shown. Considerable data are given in tabular form of physical properties and corrosion-endurance properties of the steels with various heat treatments. Effect of various temperatures is shown in tabular data on toughness determinations by means of impact tests. The solution to problem of development of 2-phase steel immune to weld decay is to produce a weld-decay free material containing a minimum of the 2nd constituent in order to prevent brittleness. Most recent development is addition of 3-4% extra Ni with 1.5-2.0 Si which gives corrosion resistance almost up to usual Ni content with 3½ Mo and without the usual brittleness. Some creep values for 538°-815° C. are tabulated. WB (11b)

Recent Developments Affecting Testing Society's Specifications for Steel Castings. R. A. BULL. *Metals & Alloys,* Vol. 7, Jan. 1936, pages 1-4; Feb. 1936, pages 35-38; Mar. 1936, pages 65-68. Discusses increased number of A.S.T.M. specifications for steel castings. Factors to be relied upon in the use of steel castings are metallurgically good casting design, proper grade of steel, dependability of available sources of supply and laboratory tests known to give reliable data on serviceability of castings in question. Mass effects in solidification and heat treatment are discussed as they affect the properties of castings. WLC (11b)

Electrical Resistivity of Faraday Steels; Gas Analysis and New Phenomena on Remelting in Radiation Furnace. CARL BENEDICKS. *Iron & Steel Institute,* May 1936, Advance Copy No. 5, 20 pages. Electric resistance of some of Faraday's steels were determined with equipment suitable for small specimens of irregular size. In 3 cases, where the electric resistance had been determined by other methods, the agreement was satisfactory. The influence of different elements on resistivity is discussed. Samples were melted in a radiation furnace and the occluded gases analyzed. Sharp corners on the specimens showed a high resistance to melting. On heating in a high vacuum pure Fe did not wet the Al_2O_3 crucible while C steels did. The difference is attributed to slight chemical reaction taking place on melting C-containing alloys. JLG (11b)

The master touch

Led by a famous conductor, a symphony orchestra gives a rendition of a great musical masterpiece that brings thunderous applause.

Yet with the same musicians playing the same notes on the same instruments, but guided by the hand of a conductor who lacks the touch of the master, the result is entirely different . . . a performance that, though mechanically perfect in detail, falls flat on the ears of the listeners.

It's the same in other fields of human effort. The work of the genuine craftsman has an excellence that cannot be measured in terms of standards fixed for the elements.

In making Bethlehem alloy steels, the guidance of masters of the art of making fine steels imparts to them a super quality, an added degree of perfection, over and above the aggregate of properties specified.

12. EFFECT OF TEMPERATURE ON METALS AND ALLOYS

L. JORDAN, SECTION EDITOR

The abstracts in this section are prepared in co-operation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

Alloys Which are Strong and Non-oxidizable at High Temperatures (Alliages tenaces et inoxydables aux temperatures elevees) P. Chevenard. *Chaleur et Industrie,* Vol. 17, Apr. 1936, pages 125-127. Paper read at the 4th Séance d'études thermiques, Dec. 1935. Methods used at the Aciéres d'Imphy for measuring creep rate, weight increase due to oxidation, and tendency to crack under cycles of heating and cooling are described. Creep limit is taken as the load which produces a mean elongation on unit length of 0.5 x 10^{-5}/hr. between the 25th and 35th hours. Typical creep rate-temperature curves are given. Strength at high temperature is shown by (1) steels with a depressed transition point such as Cr-Mo, Ni-Cr-Mo, Cr-Mo-V. These are good between 500° and 550° C., but softening effects of accidental overheating or overloading must not be overlooked; (2) complex solid solutions, usually with Ni-Fe-Cr base. These need stabilizing before use, for deformation accelerates the precipitation of carbides; (3) definite compounds, such as the sintered carbides; (4) age-hardening alloys, which should be used at temperatures below that at which precipitation occurs. Increase in the electrical resistance is used to measure the onset of cracking in samples repeatedly quenched from a high temperature. Ferritic alloys, low in C, strengthened by Cr, Cr-Si, or Cr-Al are least susceptible to cracking, and a richer alloy with 30 Cr and 5-6 Al may be used up to 1250°-1300° C. Cast irons with Cr or Mn have good non-scaling properties but lack strength. The complex Ni-Fe-Cr alloys containing Si, W, Al or Co developed at Imphy are recommended for general use, particular emphasis being placed on their stability when properly heat treated.
JCC (12)

Abbreviated Determination of Creep Strength at Variable Temperature (Abgekürzte Bestimmung der Dauerstandfestigkeit bei veränderlicher Temperatur) Max Schmidt & H. Krainer. *Mitteilungen des technischen Versuchsamtes Wein,* Vol. 24, 1935, pages 5-20. The behavior of materials under tests for creep strength is discussed and theoretically investigated which leads to a new method by Rohn. The method requires taking into account eventual sources of error due to irregular temperature distribution in the specimen and change of elasticity modulus with temperature, but as it is found that velocity of elongation and reciprocal absolute temperature have a linear relation the tests can be made in 30-48 hrs. The method is illustrated by measurements on 7 types of steel. 17 references.
Ha (12)

Standardization of Creep Testing of Steel (Vereinheitlichung des Dauerstandversuchs mit Stahl) H. Schmitz. *Stahl und Eisen,* Vol. 55, Dec. 19, 1935, pages 1523-1535. A correlated abstract giving also the recommendations of the Verein deutscher Eisenhüttenleute for creep testing. The sample should be at least 100 mm. long; the temperature over the gage length should be held constant within ± 3° C. The elongation should be measurable to 0.001% of the length. The load is applied for 45 hours after a preliminary heating period of 18 to 22 hours. 3 to 5 samples should be used with increasing loads for determining the creep limit. The rate of creep between the 25th and 35th hour is then measured, the creep limit being taken as the load which gives a rate of creep of 0.001%/hr. The total elongation after release of load also should not exceed 0.2% in 45 hours.
SE (12)

The Embrittlement of High-tensile Alloy Steels at Elevated Temperatures. W. E. Goodrich. *Iron & Steel Institute,* May 1936, Advance Copy No. 7, 17 pages. Alloy steels in the form of rounds from 1⅛" to 2" in diameter were heat treated to a tensile strength of approximately 145,000 lb./in.^{2} They were then tested to determine the effects on their Izod impact resistance of soaking at 200° and 450° C. for various periods up to 2400 hr. The effects of a constantly applied stress of 25,000 lb./in.^{2} during soaking, of intermittent temperature fluctuations from 450° to 100° C., and of the presence of initial strain were also studied. These treatments had no effect over and above that of soaking for the same period without stress or temperature fluctuation. A mildly alloyed steel with 0.6% Cr and 0.5% Mo had the greatest resistance to embrittlement. The higher the Ni and Cr contents of the steels the greater was the amount of Mo required to insure relative freedom from embrittlement. An increase in the Ni content decreased resistance to embrittlement of steels containing Cr and Mo. When comparing steels of almost the same composition samples tempered at the highest temperature had the greatest resistance to embrittlement at 450° C. All samples embrittled by heating for 2400 hr. at 450° C. exhibited a temper-brittle impact fracture, the path of rupture being partly intercrystalline. Soaking for 2400 hr. at 450° C. had practically no effect on Brinell hardness. Embrittlement was more pronounced at 450° C. than at 200° C. except for one Cr-Mo steel.

DURALOY

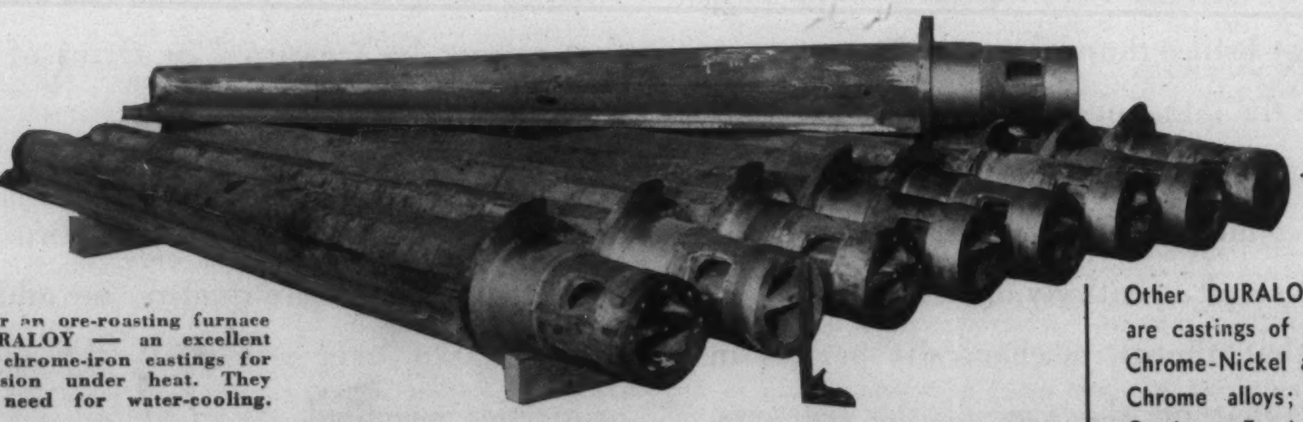
. . . where you are sure of getting *sound* Chrome-Iron Castings to meet your corrosion and high temperature problems.

Not every foundry can turn out sound Chrome-Iron castings. It takes more than foundry skill. It takes long experience in melting and pouring the many different Cr-Fe combinations available.

DURALOY has been producing Chrome-Iron castings since 1922 and retains today nearly all of the foundry men who started with the original plant.

Three electric furnaces provide ample capacity. Precise pyrometer control assures correct pouring temperatures. Our machine shop can handle any ordinary finishing job.

You will find in DURALOY just the service you want in Chrome-Iron castings. Our metallurgists will be glad to help in selecting the proper analyses.



Rabble arms for an ore-roasting furnace cast from DURALOY — an excellent application of chrome-iron castings for resisting corrosion under heat. They eliminate the need for water-cooling.

Other DURALOY products are castings of all kinds of Chrome-Nickel and Nickel-Chrome alloys; Centrifugal Castings, Forgings, Sheets, Tubes, etc.

V. V. KENDALL, SECTION EDITOR

Corrosion-Protective Value of Electrodeposited Zinc and Cadmium Coatings on Steel. William Blum, Paul W. C. Strausser & Abner Brenner. *Bureau of Standards Journal of Research,* Vol. 16, Feb. 1936, pages 185-212. Atmospheric exposure of plated specimens in 6 locations showed that in a rural or purely marine climate, both Zn and Cd coatings furnished better protection against the corrosion of steel than did Ni or Cr coatings of the same thickness, although the Zn and Cd rapidly lost their luster. In an industrial atmosphere, where H_2SO_3 and H_2SO_4 are present, both Zn and Cd were attacked rather rapidly, and the life was about proportional to the thickness. Under these conditions the Cd coatings failed in about ⅔ of the time required for failure of Zn coatings of the same thickness. Zn-Cd alloys containing about 10% Cd were superior to either Zn or Cd. Variations in the conditions selected for depositing the coatings did not have a marked effect on their protective value. Hot-dipped Zn coatings gave about the same protection as plated Zn coatings of the same thickness. In accelerated tests, such as the salt spray or intermittent immersion in a solution of NaCl, the time required for failure of a Zn coating is about proportional to its thickness. Cd coatings last much longer than those of Zn in a salt spray, which is not, therefore, a true measure of their relative value in an industrial atmosphere. The protective value of a Zn or Cd coating depends principally upon its minimum thickness, which can be determined by dropping tests, microscopic measurements, and the chord method. WAT (13)

Investigations on the Use of Aluminum in Glue Factories (Untersuchung über die Verwendung von Aluminium in Leimfabriken) *Aluminium,* Vol. 17, Dec. 1935, page 651. Al of at least 99.8% purity proved to be resistant as material in the apparatus used in glue factories, boilers, dryers, vaporizers and cooling coils, either entirely of Al or built into vessels of rustless steel. If the purity is lower (99.5%), however, the Al was corroded as the glue often contains SO_2 (about 0.4 g./kg.). These experiences were obtained in 10 French factories. Ha (13)

Research Work on Corrosion in the United States. *Engineering,* Vol. 141, Jan. 3, 1936, pages 8-9. Summary of the material contained in the reports of the four Corrosion Committees published recently by the American Society for Testing Materials. LFM (13)

Tantalum Resists Corrosion in Fountain Pen Valve. *Product Engineering,* Vol. 7, Feb. 1936, page 46. Ta resists corrosion both from ink and from contact with rubber compounds. Ha (13)

Studies on the Oxidation of Metals. Part III. The Kinetics of the Oxidation of Molten Tin. L. L. Bircumshaw & G. D. Preston. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Vol. 21, Mar. 1936, pages 686-697. The rate of oxidation of molten Sn was measured at different temperatures and pressures of O. The rate rises rapidly in the range 400°-800° C., but at any particular temperature the rate was found to vary considerably from one specimen to another. The law of oxidation for solid metals seems not to be obeyed for molten Sn, especially at low and high pressures of O. It is concluded that the rate of oxidation is not solely controlled by the progressive increase in the oxide film thickness but is determined rather by the orientation of the crystals composing the oxide film. 6 references. Remarkable Defects in Boilers (Beachtenswerte Schadenfälle an Dampfkesseln) Beckmann. *Die Wärme,* Vol. 58, Sept. 28, 1935, pages 632-634. An extract from the Annual Report of the Sächsisch-Thüringischer Dampfkessel-Revisionsverein details break-downs and defects of boilers and endeavors to bring out the source of trouble. EF (13)

Factors Contributing to Ring Wear. J. H. Ballard, S. Nixon & N. A. Moore. *Diesel Power,* Vol. 13, Feb. 1935, pages 84-86. The importance of piston ring wear as affecting the engine life is stressed. To date attempts to translate Amsler wear tests into service performance predictions have been unsuccessful. Under ideal service conditions commercial cast Fe piston rings may survive thousands of miles, but actual conditions are not ideal; wear factors to be considered are: foreign matter and abrasives, limitations of engine design and manufacture, lubrication characteristics, abuse of engines, and "blowby." The last named is most important and is closely related to distorted bores, misaligned rods, etc. and general engine design. FPP (13)

Thermomagnetic Study of the Heterogeneity of Solid Solutions (Etude Thermomagnetique de l'Heterogeneité des Solutions Solides) Pierre Chevenard. *Communications Presentées à Quatorzième Congrès de Chimie Industrielle,* Vol. 1, Oct. 21-27, 1934, 19 pages. Thermomagnetic analysis permits a delicate and quantitative evaluation of the phenomenon of heterogeneity in a ferromagnetic solid solution. The study includes an enumeration of the different factors in the phenomenon and the effects of the heterogeneity on the alloy. The author studied especially the effect on complex ferronickels resistant to intercrystalline corrosion, and of structural hardness, that is, resistance to heat and cold. At ordinary temperature the elastic limit exceeds 50 kg./mm.^{2}, and tensile strength 100 kg./mm.^{2} In alloys with additions of Cr, Al, Mo, and Ti, the constituent which is precipitated does not appear in the austenitic solution. Likewise, the hardness should not affect the chemical resistance. The immunity of these alloys to intercrystalline corrosion, which has been proven theoretically, is confirmed by these tests lasting 6000 hours. MAB (13)

The Deterioration of Colliery Winding Ropes in Service. S. M. Dixon, M. A. Hogan & S. L. Robertson. *Safety in Mines Research Board (Great Britain)* Paper No. 94, 1936, 108 pages. The results of observations and tests on nearly 250 ropes, 85 of which had broken, are summarized, and the types of deterioration classified. Corrosion-fatigue is the chief cause of rope deterioration. Methods of preventing breakages, types of ropes, their manufacture and properties, and the effect of different factors in the winding conditions on the endurance of the rope are discussed. AHE (13)

Experiences on the Maiden Voyage of S. S. "Potsdam" (Erfahrungen auf der Jungfernreise der "Potsdam") Bleicken. *Werft, Reederei & Hafen,* Vol. 17, Jan. 1, 1936, pages 1-4. A chapter of this paper reports on the failure of the condenser system on the new express liner on its maiden voyage. Al brass with 76% Cu, 22% Zn and 2% Al was used for the condenser tubes. The same material yielded a perfect record during 8 years service on other ships. The defects were primarily due to the faulty design, especially joining methods. The softening of the boiler water with Na phosphate and Na sulphite is indispensable for the formation of a protective lining in the boiler tubes to prevent corrosion defects due to free oxygen. WH (13)

Report on Protective Coatings for Underground Pipes. A. B. Densham & F. C. Smith. *Engineering,* Vol. 140, Nov. 15, 1935, page 523. From a paper read before the Institution of Gas Engineers, Nov. 1935. For protection against external corrosion of underground pipes it was found that pitch troughing or a pitch or bituminous coating reinforced with fabric was the most satisfactory. Bituminous paints and various adhesive bandages were found to be unsatisfactory. There was very little difference between the resistance of wrought iron and steel pipes to corrosion. It was found that an electrical resistance test gave a good measure of the power of a protective coating. LFM (13)

The Electric Currents Flowing Over Rusting Iron. U. R. Evans. *Nature,* Vol. 136, Nov. 16, 1935, page 792. During the corrosion of a horizontal Fe surface by a filter paper wet with $NaHCO_3$ solution it was possible to measure electric currents flowing horizontally through the paper. Non-polarizing electrodes touching the filter paper and connected to a micro-ammeter were used. Moving these over the surface in the neighborhood of a scratch intense anodic action was found immediately around scratch where corrosion was rapid. Cathodic areas were free from attack. Isolated rust spots on steel were found to be anodic. Confirms theories of electrochemical mechanism of corrosion. CSB (13)

Study of the Phenomena of the Abnormal Corrosion in Condenser Tubes. Kurazo Fukagawa & Kenichio Kamiyama. *Bulletin Institute of Physical & Chemical Research, Tokyo,* Vol. 14, Dec. 1935, pages 1241-1261. In Japanese. *Scientific Papers & Abstracts Institute of Physical & Chemical Research, Tokyo,* Vol. 28, Dec. 1935, page 73. In English. An inquiry into the abnormal corrosion of condenser tubes used in electric plants at the Setouchi sea-shore and on steamboats. The 4 different corrosion conditions observed have been imitated in laboratory experiments whereby Admiralty brass was used as testing material. WH (13)

Subcutaneous Effects During the Scaling of Steel. R. Griffiths. *Engineering,* Vol. 140, Oct. 4, 1935, pages 378-379. From a paper read before the Iron & Steel Institute, Sept. 1935. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 80R/8. LFM (13)

Recent Developments in the Use of Copper Pipe for Gas Distribution. F. A. Hough. *American Gas Journal,* Vol. 144, Jan. 1936, pages 31-33, 41. Conclusions from an earlier paper (1932) still appear valid. New evidence concerning the corrosion resisting properties of Cu is presented. Over 100 miles of Cu pipe have been installed in Southern Calif. with satisfactory results. The soils include adobe, alkali bottoms, salt marshes and submarine crossings. Cost data are also discussed. CBJ (13)

Anodic Behavior of Corrosion- and Heat-resistant Iron Alloys (Untersuchungen über das anodische Verhalten von Korrosions- und hitzebeständigen Eisenlegierungen) L. Harant. *Berg- und Hüttenmännisches Jahrbuch,* Vol. 83, Dec. 23, 1935, pages 122-127. Process of solution of anodes of different corrosion-resistant alloys in H_2SO_4 and HNO_3 was studied. Steels of approximately similar composition and structure showed also a great similarity in the dissolving process. After the passive state has been reached the solubility depends on the current density applied; at an average density there exists a sharply defined zone of perfect solubility, where all constituents of the steel dissolve in the same proportion in which they are contained in the steel. In the passive state and at the higher current densities the carbide C is oxidized so that the carbides are also dissolved. Curves show anode potentials as function of current density. 8 references. Ha (13)

Investigation into the Wear of Parts for Motor Vehicles (Untersuchung über die Abnutzung von Kraftfahrzeugteilen) F. Hanft. *Automobiltechnische Zeitschrift,* Vol. 39, Jan. 10, 1936, pages 9-19. Statistical data are compiled on the wear of parts in automobiles with time and of different materials. 15 references. Ha (13)

Test Comparative Values of Worm Gear Materials. Chester B. Hamilton, Jr. *Inco,* Vol. 13, No. 3, 1935-36, page 20. Tests with several materials for worm gears were made. A chill-cast Ni-P bronze of 87.5% Cu, 11% Sn, 1.5% Ni and 0.1 to 0.2% P was found to rank first in resistance to wear and deformation. The tests are briefly described. Ha (13)

Oxide Film of Alloys Containing Small Percentage of Aluminum. Ichiro Iitaka & Shizuo Miyake. *Nature,* Vol. 136, Sept. 14, 1935, page 437. Cu alloys containing more than 2% Al heated to red heat formed no oxide scale in several hours. The surface of a 10% Al alloy heated in contact with air blackened and gave the electron diffraction of CuO while the surface imbedded in the oxidizing flame of the Bunsen burner gave the electron diffraction pattern of γ-Al_2O_3. CSB (13)

Fight Against Corrosion in Duralumin (La Lucha contra la Corrosion en el Duraluminio) J. Lisbona. *Metalurgia y Construccion Mecanica,* Vol. 1, Jan. 1936, pages 9-10. Chemical and physical properties of duralumin (usually very pure Al with 4% Cu, 0.6% Mg and 0.6% Mn) are briefly discussed and means of protecting the surface against corrosion by anodic oxidizing treatment or coating with paint or artificial layers (of phenol, piridine, nitrocellulose, etc.) described quite generally. IRON AND STEEL EXPOSITION

Convention Hall **Detroit, Mich.**

●

September 22 to 25, 1936

●

Over 150 manufacturers of steel and steel making equipment will exhibit their products at this exposition. If you are anxious to secure your share of the huge amount being spent for new equipment, you can't afford to overlook this show. There is still space left.

●

Write, wire or phone,

IRON AND STEEL EXPOSITION
1010 Empire Building
Pittsburgh **Pa.**

The Influence of Light on the Electrode Potential and Corrosion Phenomena of Mild Steel. C. O. Bannister & R. Rigby. *Iron & Steel Institute,* May 1936, Advance Copy No. 3, 7 pages. Previous work is reviewed. An apparatus was used in which perfect control of O was possible. In the absence of O light had very little influence on the potential. With O a marked response to illumination was shown. During the first 2 days the illuminated electrode became more cathodic and during the second 2 days it became more anodic. Probable mechanism of the reactions is given and the results are compared with those obtained with non-ferrous metals. 6 references. JLG (13)

Solubility in Acid and Corrosion Resistance of Unalloyed Structural Steels (Saurelöslichkeit und Rostungsverhalten von unlegierten Baustählen) K. Daeves & F. Eisenstecken. *Stahl und Eisen,* Vol. 56, Apr. 2, 1936, pages 417-418. Acid solubility tests were made of a series of low-C structural steels according to the French method. In this a disc 3 mm. thick and 55.7 mm. in diameter is held 48 hrs. in a 30% solution of H_2SO_4 at 15°-18° C. and the loss in weight determined. The results were compared with those of atmospheric corrosion tests of the same steels. The conclusion was drawn that the acid solubility tests give no indication whatever of service behavior under ordinary corrosion conditions or any conditions other than that of acid solubility in the strength acid used. SE (13)

Wire Rope Research in Relation to Colliery Practice. M. A. Hogan. *Iron & Coal Trades Review,* Vol. 132, Apr. 10, 1936, pages 665-666; Apr. 17, 1936, page 714. The serious effects of corrosion and fatigue on ropes in mining service are discussed. There occur 2 types of wear, abrasive and plastic, the former, easily visible, by which metal is removed from the surface without changing the character of the remaining part; plastic wear, when the surface is deformed and caused to flow under heavy pressure and becomes brittle. The different reasons for fatigue and corrosion fatigue which is particularly dangerous in conjunction with internal corrosion, are explained. Factors of safety, rope examination and mechanical testing are described. Ha (13)

Factors Influencing the Rate of Attack of Mild Steels by Typical Weak Acid Media. T. P. Hoar & D. Havenhand. *Iron & Steel Institute,* Advance Copy No. 9, May 1936, 27 pages. Corrosion rates and electrolytic potentials of low-C (mostly rimmed) steels were determined in citric acid and citrate buffers. Corrosion decreased as pH increased from 1.98 to 4.98. In the more acid solutions corrosion was accelerated by S in the metal or in solution. The acceleration was attributed to stimulation of the anodic process by dissolved sulphides. Corrosion was retarded by Sn and Cd ions, which removed soluble sulphide, and by Cu in the metal, which probably also removed sulphides. Massive cementite in the steel may accelerate corrosion by assisting the cathodic process. In less acid solutions all of these effects are diminished and O becomes an important factor. Necessity of electrochemical measurements for a real understanding of the processes is emphasized. It is suggested on the basis of the work that steel for use under conditions of acid corrosion, such as the base of tin plate, should preferably be rimming steel having a Cu content not less than twice the S content. JLG (13)

Aluminum Stringer Failures Due to Fatigue Loading. Henry D. Johnson, Jr. *Engineering News-Record,* Vol. 116, Feb. 27, 1936, pages 318-320. Poorly placed ties on the Smithfield Street Bridge at Pittsburgh concentrated loads on edge of outstanding legs of flanges and subjected them to repeated stresses above the yield point. After 2 years service the condition of the Al-alloy floor system is summarized as follows: 1. The mechanical condition of the Al-members is good with the exception of the stringer flange angles which have been repaired. 2. The field coats of Al paint show deterioration at numerous points on the under side of the bridge, although the priming coat is in good condition. 3. There is no evidence of more than superficial surface corrosion of any Al alloy part. 4. There is no evidence of electrolytic corrosion or corrosion at joints either between Al and Al or Al and steel. CBJ (13)

Erosive Action in Steam Plants. Edward Ingham. *Power & Works Engineer,* Vol. 31, Feb. 1936, pages 62-63. Erosion of boilers and fans by flue dusts, scoring of steam valves and seatings by erosion as well as corrosion, and erosion of turbine blading are discussed. Dust particles should be largely removed from flue gases to prevent fan erosion. Valves and seatings must be finely finished with absolute absence of leaks to avoid erosion. The use of special alloy steels for turbine blades reduces their erosion. FPP (13)

Studies on the Wear of Metals in Gliding Friction (Untersuchungen über das Verschleissverhalten der Metalle bei gleitender Reibung) B. Kehl & E. Siebel. *Archiv für das Eisenhüttenwesen,* Vol. 9, May 1936, pages 563-570. Flat ring samples of steel and cast iron were used, the flat surfaces of 2 rings rubbing against each other as one of the rings revolved. On testing dry the wear increased directly with the load. After surface oxidation started the temperature of the rings rose to above 250° C. Between a speed of 0.2 to 1 m./sec. the wear decreased with increasing speed; beyond this speed the wear increased again. The wear resistance of pearlitic cast Fe increased with the hardness; in C steel a decided decrease in wear only occurred when a martensitic structure was present. When 2 different cast-irons rub against each other the harder one wears more and the softer one less than if both samples were of the same Fe. Harder cast Fe tends to corrode more than soft during wear. Wear and corrosion under oil increased with the roughness of surface. The wear decreased under pure oil as the time of test was prolonged; speed had little effect. Increased loading increased the wear proportionately at first and then as seizing or corrosion occurred the wear increased as much as 100 fold. The results were considered to bear a good correlation with certain service conditions. SE (13)

Corrosion at Permanent and Elastic Deformation (Korrosion bei bleibender und elastischer Verformung) W. O. Kroenig & A. J. Boulitschewa. *Korrosion & Metallschutz,* Vol. 12, Apr. 1936, pages 73-81. Corroding influences exert a different effect depending on whether the material is in a static or dynamic state; a specimen subject to a corrosion test illustrates the former, a part in an engine the latter case. These effects were investigated on Al, duralumin, brass and Fe, and it was found that the electrode potential of the metal or alloy is shifted towards baser values with increasing mechanical stresses, and that the corrosion resistance becomes lower with increasing stress; this resistance was in some solutions 10 times less for stressed than for unstressed specimens. Fe, brass and duralumin have a tendency to intercrystalline corrosion under elastic deformation which is not observed in the unstressed state. 13 references. Ha (13)

Corrosion Resistance of Metals and Alloys. ROBERT J. McKAY & ROBERT WORTHINGTON. Reinhold Publishing Corporation, New York, 1936. Cloth, 6 x 9¼ inches, 492 pages. Price $7.00.

This is No. 71 in the American Chemical Society Monograph series. Corrosion phenomena are notoriously difficult to control and equally difficult to understand, because of the complexity of the variables. This book is a real contribution toward intelligent unscrambling of the variables, toward clear thinking, and hence toward correct understanding and ultimate control. The preliminary chapters on the factors that enter into corrosion and that control corrosion rates, put the reader into the proper frame of mind to accept the authors' warning that the many tables of corrosion rates are to be considered as giving only a general appraisal and not figures from which the life can be calculated down to a day. Really getting that across is no small achievement.

The metals and alloys are taken up in the order: Mg, Al, Zn, Cd, Sn, Pb, Fe, FeSi, Mo, Cr, FeNi, Ni, NiCu, Cu. Under each metal, the corroding materials and environments that the metal resists or fails under, are discussed.

Corrosion-fatigue is dealt with wherever data are available. The question of galvanic attack in contact with other metals is discussed for each metal and alloy. Corrosion in tin cans by various food products is dealt with at quite some length, giving a very good birds-eye view of the problem. Other metal-coated metals are adequately discussed. The authors do not accept the usual view that light, i.e., thin, zinc coatings are to be preferred when galvanized steel must undergo bending.

The discussion of the activity-passivity relations of 18:8 and its congeners and of intergranular attack is both clear and concise.

The behavior of the various alloys in various atmospheres at high temperatures is included as a corrosion phenomenon, though seldom dealt with in as much detail as other types of corrosion. Except for this, little is said about corrosion under non-aqueous conditions, the interesting subject of corrosion of bearing metals not being touched upon.

The authors have spared the reader from having to cope with a complete bibliography, and confine themselves to a selected one, even the chapter on iron and steel requiring but 134 references. The book is well indexed. At the ends of chapters where a blank page or part of a page would normally occur, sketches of a demon "Old Man Corrosion," drawn by the junior author, enliven the pages.

The book is much more than a compilation of existing data on corrosion and corrosion rates for it not only gives the data but continually ties it in together so that the reader is made to consider the processes of corrosion that are going on. Since it covers the most important industrial alloys and handles its subject in such a thoughtful way, it is the best source of information on corrosion in general yet published. H. W. Gillett (13) -B-

Corrosion Resistance of Welds (Korrosionsbeständigkeit von Schweissungen) BÜRGEL. *Autogene Metallbearbeitung,* Vol. 29, May 15, 1936, pages 148-154. The behavior of a metal and of welds of the same or different metals against attack is investigated. Carefully and correctly made gas fusion welds possess, in most cases, at least the same corrosion resistance as the base material, and often a much higher corrosion resistance. Sometimes the transition zone is particularly sensitive, e.g. to HCl, so that this zone is more strongly attacked and more easily destroyed. The reason for this condition is the increase in grain size due to the temperature in this zone. Fine grain shows a greater corrosion resistance than coarse grain. Metal alloys without eutectic are more corrosion resistant than metals with eutectic. Ha (13)

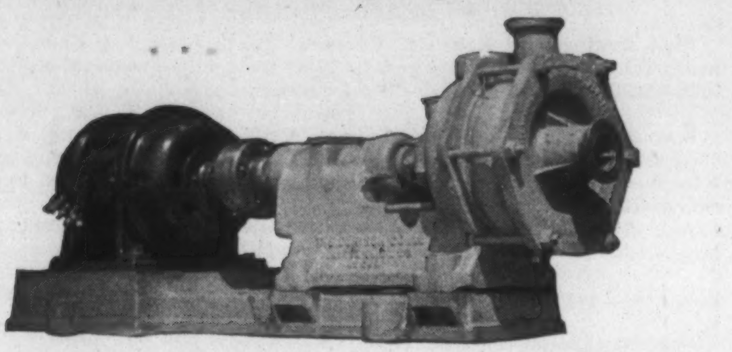
Effect of Sodium Silicate Containing Soda on Differently Pretreated Light Metal (Ueber die Einwirkung von wasserglashaltiger Soda auf verschiedenartig vorbehandeltes Leichtmetall) H. BOHNER. *Aluminium,* Vol. 18, Mar. 1936, pages 102-103. When dipping Al and Al alloys as rolled in a boiling, Na silicate solution containing soda, an instantaneous H evolution takes place in material (1) pickled in HCl up to 2 min., (2) scoured with steel wool, or (3) pickled in NaOH; no further effect is noticed. In material, however, which was sandblasted, or pickled longer than 2 min. in HCl, the H evolution lasts much longer. The stronger the attack of the light metal by HCl, the longer the soda solution with Na silicate must act to produce the protective action. Tests are described in detail. Ha (13)

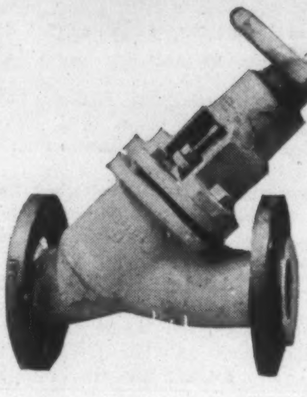
Piston Treatment and Wear. *Gas & Oil Power,* Vol. 30, Dec. 1935, page 296. A note on present status of use of Al pistons in heavy oil engines. FPP (13)

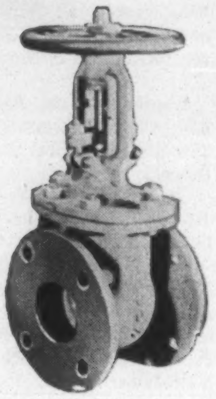
Corrosion and Construction (Korrosion und Konstruktion) KURT ADLOFF. *Die Wärme,* Vol. 59, Jan. 18, 1936, pages 38-42. Discusses corrosion and strength, combatting corrosion by proper design, effect of various anti-corrosion means on the corrosion fatigue of different steels. EF (13)

Corrosion from Products of Combustion of Gas—Part III. The Experiments (continued). 36th Report of the Joint Research Committee of the Institution and Leeds University. JAMES W. WOOD & E. PARRISH. *Institution of Gas Engineers, Communication* No. 121, 1935, 47 pages; *Gas World,* Vol. 103, Nov. 9, 1935, pages 421-422, 431-438; Dec. 7, 1935, pages 540-541; *Gas Journal,* Vol. 212, Nov. 13, 1935, pages 470-472; Dec. 4, 1935, pages 692-693. The products of combustion of gas containing 8.1 grains S/100 ft.^{3} were led through tubes of various composition and the results compared with previous similar experiments with gas containing 25.6 and 51.2 grains S. With the gases of higher-S content, the corrosion products remained in solution; in the present tests there was a tendency for the condensates to throw down precipitates. The rate of corrosion from beginning to end of the tests (as judged by the amount of metal in the condensates) was remarkably uniform for individual materials (with higher S gases there was an initial period of relatively severe attack). When the metals are arranged in order of resistance to corrosion, their sequence is substantially the same for all S concentrations. The metals fall into 3 groups having good, medium and poor resistance to corrosion. Pb, Sn, and solder show a marked superiority to other metals. As the S content of the gas is reduced, the difference between metals of the good and medium groups becomes less pronounced. The metals in the medium group are Al, 70/30 brass, hard Cu and soft Cu. The least resistant metals are Fe, Zn and Ni. The rate of corrosion falls as the S content of the gas is reduced, but the fall is appreciably less than would be expected if corrosion is proportional to S content. The S retained in condensates from the low S gas was 11.4-95.9% that in the gas burned and in every case was a higher proportion of the S originally present than when using gas of higher S content. There was less free acid than before. HNO_3 was never less, sometimes much greater, than in tests with high S. With the resistant materials, the HNO_3 in solution was fairly constant at 0.003-0.005 g./100 cc. AHE (13)

Standard Equipment

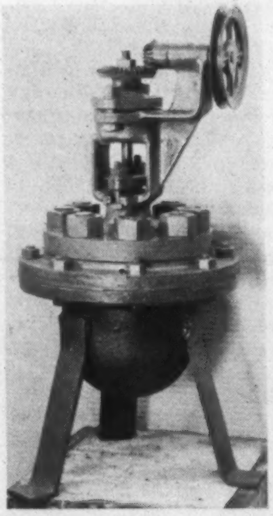


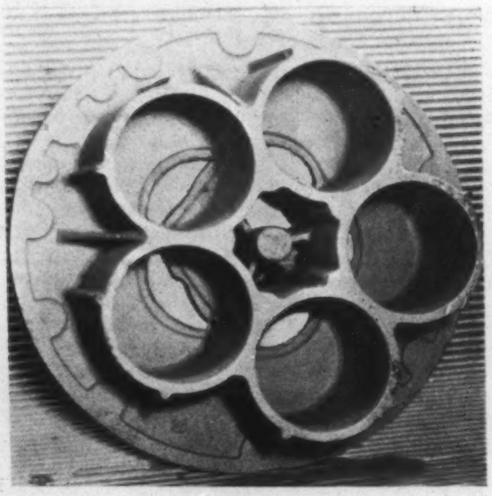




or

Special Equipment





in corrosion-resisting

DURCO ALLOY STEELS

Standard Equipment

Centrifugal pumps in sizes from 1" suction, 1" discharge to 8" suction, 6" discharge; Y valves, gate valves and lubricated valves with screwed ends, split-flange ends or integral flanges; elbows, tees, crosses, unions, plugs, caps and couplings, and other equipment for corrosion service.

Special Equipment

In either simple or complex forms, rough or finished castings, will be made to your specifications from suitable patterns, of the correct analysis for the service intended.

Bulletin No. 171 and Circular No. 103 contain information on Durimet and Durco Alloy Steels and equipment. Copies will be sent you upon request.

Photographs on Electrolytically Oxidized Aluminum (Das Lichtbild auf elektrolytisch oxydiertem Aluminium; Seo-Foto-Verfahren) Alexander Jenny. *Chemiker Zeitung,* Vol. 60, Mar. 25, 1936, pages 257-258. The development of photographic images on oxidized Al has opened an entirely new field of photography. The process consists in impregnating the previously produced "eloxal" film with a solution of an optically sensitive chemical, and subjecting the sensitized film to the customary photochemical treatment. Successful imagine production depends on the thickness, adherence, porosity and hardness of the oxide film. Careful cleaning of the film pores by treatment in hot water or organic solvents is essential. Advantages claimed are the general resistance of such photographs to fire and heat, organic solvents, and abrasion. The cost of such Al oxide photographs is little higher than that of customary reproductions. See also *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 84R/6. FPP (14a)

Aluminium Alloys in Shipbuilding and Marine Engineering. J. W. Donaldson. *Metallurgia,* Vol. 13, May 1936, pages 173-177. Describes applications and alloys used. JLG (14a)

Fifty Years March of Aluminum. F. Reed Dallye. *Electrical World,* Vol. 106, Feb. 15, 1936, pages 24-26. Use of Al as busbar material, for transmission and distribution conductor, and in coil windings is discussed. CBJ (14a)

Aluminum 1936 Practice. F. V. Hartman. *American Machinist,* Vol. 80, Feb. 26, 1936, pages 185-192. The different processes developed for shaping Al, working methods and welding processes are reviewed and modern applications described. Ha (14a)

Development of Aluminum for Aircraft. C. F. Nagel, Jr. *Aero Digest,* Vol. 28, Feb. 1936, pages 27-29, 84. General. WB (14a)

Aluminum is Fifty. Lewis K. Urquhart. *Factory Management & Maintenance,* Vol. 94, Feb. 1936, pages 70-71. New uses of Al discussed include: all-Al train, fire-resistant and fire-retarding partitions on ships, architecture, interior decoration and colored Al. CBJ (14a)

Aluminum Connecting Rods. R. L. Templin. *Mechanical Engineering,* Vol. 58, Mar. 1936, pages 169-170. A forging alloy of 4.4% Cu, 0.8% Si, 0.75% Mn, remainder Al, was used successfully in a large freight locomotive. The stress distribution in the rod was investigated and is diagrammatically explained. Ha (14a)

Properties of Lead-Calcium Alloys for Storage Cell Grids and Plates. Earle E. Schumacher & G. S. Phipps. *Metal Industry,* London, Vol. 47, Nov. 22, 1935, pages 512-513. An abridged form of the original paper. See *Metals & Alloys,* Vol. 7, May 1936, page MA 265L/8. HBG (14a)

Tin and Its Utilisation. *Chemical Trade Journal & Chemical Engineer,* Vol. 95, Aug. 17, 1934, pages 111-112. MS (14a)

Aluminum Celebrates Its Fiftieth Anniversary. *Mill & Factory,* Vol. 18, Feb. 1936, pages 53-56 and 116-117. Reviews history and modern uses of Al and its alloys. FPP (14a)

Air Preheaters and Exhaust Pipes of Airplane Motors Made of Inconel (Auspufftöpfe mit Luftvorwärmung aus Inconel für Flugmotoren) *Nickel Berichte,* Vol. 6, Feb. 1936, pages 21-23. The alloy containing 80% Ni, 14% Cr, 6% Fe withstands the temperature of 600°-750° C. of the exhaust gases. The rather complicated construction is assembled by welding. EF (14a)

Aluminum-Copper Alloys. Foundry Practice and Properties. *Metal Industry,* London, Vol. 47, Oct. 11, 1935, pages 368-371; Oct. 18, 1935, pages 391-394. Report of Non-Ferrous Division of A. F. A., in abridged form, which contains practical information for the foundrymen who handle non-ferrous alloys. HBG (14a)

Aluminum Pistons: Details to be Observed to Insure Successful Operation. P. B. Jackson. *Diesel Power,* Vol. 14, Mar. 1936, pages 170-173. To permit high speed operation Al alloys are being employed as Diesel piston materials. Satisfactory performance depends on observance of several fundamental precautions. Piston proportions, i.e. the length and location of wristpin, length of ring belt, amount of space between ring and piston top, piston head design, thickness of metal in the piston head, size of piston rings, dimensions of piston skirt, use of bearings and bosses and composite piston design are discussed as factors affecting the technical and economic advantages of Al alloys as pistons. FPP (14a)

Aluminium in Rolling Stock Construction. Ernest V. Pannell. *Railway Gazette,* Vol. 64, Mar. 27, 1936, pages 613-614. The important effects of train weight on energy or fuel consumption and on permanent way maintenance are discussed. Weight reduction must not sacrifice strength, and Al alloys offer cumulative advantage in this respect. Additional advantage of Al alloys is their very low modulus of elasticity which reduces the disastrous effect of possible railroad collisions. A review of present application of Al to train construction in America and Great Britain is included. FPP (14a)

Non-Ferrous Metals. *Times [London] Trade & Engineering,* Vol. 38, Jan. 1936, page XVII. Reviews developments during 1935 in industrial applications of alloys, metal protection processes, and research. MS (14a)

Cost Savings Afforded by Alloy Anchorage of Punches and Dies. *Steel,* Vol. 98, Mar. 30, 1936, pages 35-36. Cost of complicated assembly of punches and dies can be reduced substantially by machining the punches and dies in separate sections, mounting them in a shoe or die-block, and cementing them in place with Cerromatrix. Punch assemblies are located by fitting them into punch plate. They are then fastened to an auxiliary holding plate by means of screws. Regular punch holder is clamped to auxiliary plate and entire assembly is withdrawn from punch plate. Assembly is inverted, preheated from below to prevent drawing temper of hardened parts, and alloy is poured. Cerromatrix is composed of Bi, Pb, Sn, and Sb; has a tensile strength of 13,000 lbs./in.^{2}, Brinell hardness of 19, and elongation of less than 1%; and is sufficiently hard to hold punch and die parts permanently in their proper locations. Its m.p. is 248° F., pouring range, 300°-350° F., and freezing range, 260°-216° F. It should be allowed to stand for 12 hrs. after pouring as it age hardens. It expands approximately 0.002"/in. on cooling. It in no way "wets" the steel, and therefore, it is necessary to provide a mechanical anchorage from alloy to piece to be held and from alloy to holding medium. Die-blocks and punches must rest firmly against a solid steel or Fe foundation and no alloy must be allowed to flow beneath either die-block or punch. Other uses of alloy are material for molds for pressing cold-formed plastics, short-run forming dies for light-gage sheet-metal, stripper plates, etc. MS (14a)

Sectional Steel Poles. *Electrician,* Vol. 116, Apr. 24, 1936, pages 552-553. Light-weight sectional steel poles for supporting overhead lines or lamp standards used in Europe are described. CBJ (14b)

Scrap-Rail Flooring Mats Withstand Severe Abuse. *Railway Engineering & Maintenance,* Vol. 32, Apr. 1936, page 243. The Erie Railroad has effectively used scrap rails as flooring at local spots in locomotive shops subject to unusually severe wear or abuse. Lengths of rails, laid base up and parallel to form a mat, are grouted into the floor. The grout filler prevents possible breakage of the base flanges. Sections of such rail mat floorings are still in service after more than a year. FPP (14b)

Cold Heading Dies and Die Steels. J. C. Alexander. *Heat Treating & Forging,* Vol. 22, Apr. 1936, pages 171-173. See *Metals & Alloys,* Vol. 7, May 1936, page MA 265R/10. MS (14b)

Prolonging the Life of Rails. C. B. Bronson. *Railway Engineering & Maintenance,* Vol. 32, May 1936, pages 302-305. From a paper presented before International Railway Maintenance Club. Rail renewals are required because of direct rail failures (crushed heads, fissure and base breaks, web cracks etc.), joint conditions, head wear, rails damaged by faulty equipment, and corrosion. Corrosion and joint problems are most serious. Poor joints may often be salvaged by welding repair, but defects should be removed from joint bars. Reference is made to importance of rail manufacturing methods and to H. F. Moore's investigation of transverse fissures and cooling conditions. FPP (14b)

Coal Cutter Picks. A. J. Beeley. *Edgar Allen-Buell Gazette,* Vol. 2, Mar.-Apr. 1936, pages 131-134. The best material for coal cutting tools is a rather dense steel of fine grain; the temperatures in heat treatment should be carefully observed as otherwise coarse crystals and brittleness might occur. Prescription for the treatment of a special steel (composition not given) is given in detail. Ha (14b)

Steels for Dies for Plastic Materials. *Edgar Allen News,* Vol. 14, Apr. 1936, pages 824-825. The various steels manufactured by the Edgar Allen Co. and their heat treatment and mechanical working are described briefly. Ha (14b)

Standard Specifications for Lock-Bar Steel Pipe. *American Society for Testing Materials,* A. S. T. M. Designation: A 137-34; *American Standards Association,* A. S. A. No.: B 36.7-1935, 5 pages. AHE (14b)

Nickel Steel Saves Weight, Prolongs Life of Boilers and Fireboxes. R. E. PENROD. *Steel,* Vol. 98, Mar. 23, 1936, pages 53, 55. Lehigh Valley Railroad has put 27 new locomotives in service since 1931, in which Ni-steel plate is used for boiler and fire-box elements. They were fabricated by 2 different builders, each using a different composition of steel. These locomotives have been in almost continuous service without need for repairs to either boiler or fire-boxes. Minimum tensile strength of boiler steel was specified as 75,000 lbs./in.^{2} and of fire-box steel as 65,000 lbs./in.^{2} making possible a saving of 9000 lbs. in overall weight of each unit. MS (14b)

Locked Coil Winding Ropes. RICHARD SAXTON. *Metallurgia,* Vol. 13, Feb. 1936, pages 117-118. Describes different designs of locked-coil rope and discusses problems arising in their manufacture. JLG (14b)

Foreign Raw Materials for Special Steels for Chemical Equipment (Beitrag zur Frage der ausländischen Rohstoffe in Sonderstählen des chemischen Apparatebaus) P. SCHAFMEISTER. *Technische Mitteilungen Krupp,* Vol. 3, Nov. 1935, pages 218-223. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 153L/5. Ha (14b)

Nickel Alloy Constructional Steels. D. A. NEMSER. *Modern Machine Shop,* Vol. 8, Mar. 1936, pages 40-48. The various uses of Ni alloy steels in the tool and die fields are discussed, their classification according to SAE specifications explained, their composition and heat treatment described, and tables of mechanical properties given. Ha (14b)

Progress in the Production of Cast Iron for Locomotive Parts. A. REYBURN. *Transactions American Foundrymen's Association,* Vol. 6, Dec. 1935, pages 151-160. Following the World War, Canadian railroads were rehabilitated and larger and heavier motive power was introduced. Failures of locomotive cylinders in this heavier equipment focused attention on cast Fe. The new developments resulted in a new specification requiring a cast Fe with an analysis as follows: Si 0.80-1.10% (0.90 desired), S 0.11% maximum, Mn 0.80-1.00% (1.00 desired), P 0.20% maximum, total C 3.00-3.20%, Ni 0.75% minimum, and a Brinell hardness of 240 and a deflection of 0.13″ on 1¼″ diameter bar, 12″ centers, load 4,000 lbs. The types of irons used for such parts as cylinder liners, valve bushings, pistons, bullrings, and packing-rings together with the general molding and core-making practice for cylinders are outlined. The use of Ni and Ni-Cr cast irons has in several instances increased life of parts and saved considerable cost to the railroads. CEJ (14b)

Yoloy—Its Properties and Welding. FRED J. ESSLINGER. *Welding Journal,* N. Y., Vol. 15, Jan. 1936, pages 18-19. Discussion of a new Youngstown Sheet and Tube Co. product, a high tensile, low alloy steel whose superior properties are due to the alloying elements, P, Cu and Ni. Compared with mild steel it has yield point almost doubled, very high tensile strength and fair ductility. Atmospheric and soil corrosion resistance is stated to be superior together with excellent fatigue and impact resistance. An important feature of the material is that its strength is increased by heating to 1000-1200° F. and cooling, and because of this it is considered to be especially suitable for welding pressure vessels, etc. No difficulties met with in welding with fluxed wire in the low C contents, but higher C contents require preheating and bottom layer of mild steel which may or may not be chipped out as conditions require. Stress relief of welded sections considered almost indispensable, procedure being 1½ hrs. at 1200° F. for each 1″ of thickness. Tables of mechanical properties are presented. WB (14b)

Forty-Five Tons of Steel Used in Building this House. *Steel,* Vol. 97, Dec. 9, 1935, pages 17-18. Describes house under construction near Toledo, O., which employs welded steel frame. Floors and walls use about 43½ tons of steel, while about 1½ tons are in loose lintels. MS (14b)

Resilient Post Bracket Supports Free Cables in New Highway Guard. *Steel,* Vol. 97, Dec. 9, 1935, page 50. Development of American Steel & Wire Co. Cables are held taut by 2 end anchor posts, but are free to move horizontally through intermediate post brackets. Bracket is shaped to provide flexibility under direct impact from moving vehicle. Recommended composition of steel for brackets is 0.60-0.75% C, 0.40-0.70% Mn, 0.05% maximum S, and 0.04% maximum P. Hardness after tempering should be 40-45 Rockwell C. Cables and fittings are galvanized. MS (14b)

Stresses in the Steel Reinforcement of Reinforced Concrete Structures. R. H. EVANS. *Structural Engineer,* Vol. 63, Sept. 1935, pages 354-369. Paper before the Yorkshire Branch of the Institution of Structural Engineers at Leeds, Mar. 1935, contains 11 diagrams and bibliography. WH (14b)

Steel Alloys. WALTER M. MITCHELL. *Food Industries,* Vol. 7, Dec. 1935, pages 577-579. Strength, non-corrosive properties, light weight in fabricated forms and a permanent bright, clean appearance are properties of stainless steel of the 18-8 type of particular importance in handling foods. There is no deleterious action of 18-8 on foods. Stainless alloys are much used in equipment for handling fruit juices, in wineries and breweries and in the dairy industry. The use of "stabilized" 18-8 is advocated for beer tanks and vats fabricated by welding and in other applications where corrosive conditions are met. Such stabilization against danger of locally increased susceptibility to chemical attack is accomplished by the addition of Ti or Cb followed by a suitable heat treatment. BWG (14b)

Making Forgings for Otis Elevators. J. B. NEALEY. *Heat Treating & Forging,* Vol. 21, Nov. 1935, pages 522-523. Describes steel foundry and machine-shop of Otis Elevator Co. at Buffalo, N. Y. Foundry has a 1000-lb. and 2 6-ton electric melting-furnaces and 3 gas-fired car-bottom type ovens for drying molds. Forge department has 7 gas-fired furnaces. MS (14b)

Key Words to the Metallurgy of Steel. Second Edition. G. A. DEBELIN & E. E. G. BRADBURY. Greenup & Thompson, Ltd., Sheffield, England, 1935. Paper, 4 x 6 inches, 46 pages. Price 9d.

This little book contains key words to the metallurgy of steel, and is intended primarily for practical men. In the preface it states: "While the authors believe that the definitions are not scientifically inaccurate, their object has been to achieve lucidity from the point of view of the ordinary individual, although this may occasionally have involved some looseness of phrasing." In spite of this the booklet should be very useful. R. Rimbach (15) -B-

VDI Jahrbuch 1936. Die Chronik der Technik. VDI Verlag GMBH, Berlin 1936. Paper, 5¾ x 8¼ inches, 192 pages. Price 3.50 RM.

The third volume of the VDI-Jahrbuch, which gives an annual bird's eye view of the developments made in all branches of science, has been prepared by 85 specialists under the direction of G. Garbtotz, Director of the Verein deutscher Ingenieure. Six thousand references are mentioned and 2300 subject listings are included.

The second volume of the Jahrbuch appeared in 1936 and contained 183 pages (Price 3.50 RM); 5000 literature references. The review of Vol. 1 of the Jahrbuch appeared in *Metals & Alloys,* Vol. 5, June 1934, page MA 300. R. Rimbach (15) -B-

Invention and the Law. H. A. TOULMIN, Jr., Prentice-Hall, Inc., New York, 1936. Cloth, 6 x 9 inches, 399 pages. Price $5.08.

This discussion of what is and is not patentable is primarily aimed to help the patent lawyer by collecting court findings that bring out the various points. Much of the text consists of excerpts from court decisions and there is a copious bibliography. These are chosen to express general principles without going into detail as to the exact features of the case in question. This gives the reader little aid in grasping the abstract principles through the means of an easily visualized specific example, but it keeps out the danger of having the reader's mind wander from the main track.

The book stresses that an invention may be a real and patentable invention even though it may be extremely simple, and that it is the last step that counts. The comments on transference from one art to another are helpful. One wishes that the doctrine of equivalents in compositions of matter had been more fully dealt with.

English patent practice is discussed because of its analogy to American practice, that of other countries is not covered in detail.

Most such books are of doubtful value to those up against patent matters but not versed in patent law. This is distinctly more intelligible to the general reader than the common run. H.W. Gillett (15) -B-

Advertising and Selling Industrial Goods. VERGIL D. REED. Ronald Press Company, New York, 1936. Cloth, 5¾ x 8½ inches, 287 pages. Price $3.50.

Mr. Reed, who is Associate Professor of Marketing and Foreign Trade, Boston University, is also Chief, Retail and Wholesale Trade, Bureau of the Census, U. S. Department of Commerce.

The volume deals with the strategy, tactics and technique involved in advertising and sales promotion of industrial goods. It prevents practical suggestions to advertising and sales executives as a guide in the development of sound plans. The subject is presented in a manner to be helpful to small and medium sized companies, which are dependent upon the most effective use of limited appropriations to attain their marketing objectives.. R. Rimbach (15) -B-

Research Laboratory of the London, Midland and Southern Railway. *Metal Industry,* London, Vol. 47, Dec. 13, 1935, pages 591-593. A description of the opening of the new research laboratory of this company by Lord Rutherford of Nelson. The history of the beginning and growth of railway laboratories is related and the development of the research policy is outlined. The functions of the different sections are indicated and the different rooms and their equipment are described. HBG (15)

Production, Heat Treatment, and Properties of Iron Alloys. LOUIS JORDAN. *National Bureau of Standards Circular,* C 409, Mar. 17, 1936, 40 pages. Prepared in response to many requests for a brief and simplified statement of the principles of the heat treatment of steels and for a similarly simplified statement covering the production and properties of Fe alloys in general. This circular gives particular consideration to recently developed theories of the hardening of steel and the role of special alloying elements in steel. It describes very briefly the reduction of Fe ore, the production and properties of cast Fe, production and fabrication of steel, and also discusses the fundamental principles upon which the heat treatment of steel is based. There are also included brief discussions of the equipment used in heat treating processes and the major types and chief characteristic properties of alloy steels. LJW (15)

What do Recent Developments in Non-Ferrous Metallurgy Bring to the Ferrous Metallurgist? (Was bringt dem Eisenhüttenmann die neuere Entwicklung in der Technik der Nichteisenmetalle?) G. MASING. *Stahl und Eisen,* Vol. 56, Apr. 16, 1936, pages 457-465. Recent developments in non-ferrous metallurgy are discussed and their bearing on or similarity to ferrous metallurgical problems brought out. SE (15)

Review of Iron and Steel Literature for 1935. E. H. MCCLELLAND. *Blast Furnace & Steel Plant,* Vol. 24, Jan. 1936, pages 59-64; *Heat Treating & Forging,* Vol. 22, Jan. 1936, pages 25-30. 19th annual classified list of the more important separately published books and pamphlets of the year, with a few of 1934 not available for inclusion in last year's list. Will be reprinted, with additions, by the Carnegie Library of Pittsburgh and may be obtained gratis. MS (15)

The Role of Patents in Modern Metallurgy. ANTHONY WILLIAM DELLER. *Metals & Alloys,* Vol. 6, Nov. 1935, pages 313-316. 22 references. Discussion of the use and value of patents in protecting inventions. Several metallurgical patents and cases growing out of them are discussed. WLC (15)

Post-war Development of the Swedish Iron and Steel Industry. K. WISTRAND. *Iron & Coal Trades Review,* Vol. 132, May 1, 1936, page 805. Ha (15a)

The Soviet Non-Ferrous Metal Industries—Some Recent Developments Reviewed. *Metal Industry,* London, Vol. 47, Dec. 6, 1935, page 563. Due to the introduction of modern methods, the non-ferrous metal industry of the Soviet Union has proved this to be one of the richest countries in these metals. It is expected that by the beginning of the Third Five-Year Plan, the Soviet Union should occupy first place in production in Europe and an important place in world economics. Due to the location of the deposits there are a number of difficulties to be overcome such as an adequate supply of fresh water, available labor and necessary training of personnel. The technique in all of these industries is being brought up-to-date and experiments on the utilization of raw materials and waste products have been successful. HBG (15a)

Metallurgy in Belgium and the Belgian Congo (La Métallurgie en Belgique et au Congo Belge). E. PROST. Dunod, Paris, 1936. Paper, 4¾ x 7½ inches, 340 pages. Price 35 Fr.

Historical, tracing developments since 1345, also descriptive of the present situation, listing the firms in operation and giving many world production statistics. The description of the devastation of the Belgian steel works by the Germans during the war carries such adjectives as abominable, bestial and barbarous, indicating that German behavior has not been forgiven. Emphasis is laid on the importance of electric melting of steel and of electric melting and duplexing of cast Fe in present day Belgian practice.

Considerable attention is paid to the various past and present Zn furnaces. The N. J. Zinc vertical retort is rated as well worth the attention of the Belgian producers. Competition of electrolytic Zn, with its purer product is noted. Because of Belgium's water power, it is considered fitting that electrolytic should advance there, and Vielle-Montague is installing equipment to produce 500 tons per month at one plant, and has an electrolytic operation going at another plant that produced 22,000 tons in 1934. The Cd production is being stepped up, the rising price having brought back into production a Belgian plant whose Cd department was closed from 1931 to 1935.

Attention is then paid to Belgian refining of Pb, Ag, Cu, Ni and Sb. The scene then shifts to the Belgian Congo, with discussion of Cu, Co, Au, Sn and Ra, on which the technical discussion is very brief.

The book is of considerable interest from the economic point of view. On the technical side, the information is rather scanty, though Zn is treated more fully than the other metals. H. W. Gillett (15a) -B-

Metallurgy, Mechanical and Electrical Construction (Métallurgie, Construction Mecanique et Electrique). D. HALLET, Brussels, 1935. Paper, 5 x 8¾ inches, 224 pages. Price 50 Belgian Fr.

This publication classifies geographically and by products the metallurgical and engineering companies in Belgium and Luxembourg. Lists of professional, trade and sales associations, as well as an index of supplies to the metallurgical industries are included. R. Rimbach (15a) -B-

FREE SERVICE DEPARTMENT

Wanted:—By a well-known manufacturer of Heat and Acid Resisting Castings Sales Representatives who are acquainted with buyers and operating heads in the Steel, Automobile, Chemical and Oil Industries in the following territories: New York, Boston, Philadelphia, Chicago, Cincinnati, Houston and Birmingham. No objection to one or two more lines. Reply giving references and full information as to qualifications. Address Box MA-2, Care of Metals & Alloys, 330 W. 42nd St., New York, N. Y.

REPRESENTATIVE WANTED—A manufacturer of heat resisting alloys and castings seeks representation in both the Philadelphia and New England territories. We are looking for a manufacturer's representative now calling on metal working plants who has the entree to the heat treating supplies market. Write Box No. MA-3, METALS & ALLOYS, 330 42nd Street, New York, N. Y.

Junior Executive Available—M. I. T. Graduate. General engineering experience, Chase Brass and Copper Company. Purchasing chemicals and equipment, R. H. Macy and Company. Single, Christian, references. Box No. MA-4, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

POSITION WANTED: INSPECTOR, SUPERVISOR or INSTRUCTOR of WELDING. Specialized 8 years in arc welding. Knowledge of Metallography, Heat-Treating and Physical Metallurgy. Capable of performing tests and conducting investigations of Weld-Metal. Sales experience. Member of American Welding Socy. and American Socy. for Metals. Good Linguist. Consider position outside U. S. Available July First. Address box MA-6, care of METALS & ALLOYS, 330 W. 42nd Street, New York, N. Y.

MARKET RESEARCH SPECIALIST with a good technical background. Complete developing and marketing experience on electrical and chemical specialties and instruments. Salary or fee basis. Box MA-9, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

METALLURGIST, TESTING, OR RESEARCH ENGINEER POSITION WANTED: Age 29. Five years' experience in physical metallurgy, metallography, material testing, including fatigue, at temperatures from +70° F. to —50° F., metal inspection, and design of special testing machine equipment. Some experience in heat treating. University graduate, M. S. degree. Now employed on nearly completed investigation. Available on or before Jan. 1st. Box MA-10, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

REPRESENTATIVE WANTED: Industrial furnace manufacturer wants experienced sales engineer familiar with middle west territory and with some metallurgical knowledge. Commission bassis. Address Box MA-12, c/o METALS & ALLOYS, 330 West 42nd St., New York, N. Y.

AVAILABLE — METALLURGIST — Technical graduate — 35 years—8 years metallurgical supervision over all phases of special ssteel manufacture, including melting. Address Box MA-11, c/o METALS & ALLOYS, 330 West 42nd St., New York, N. Y.

An Outline of Steel and Iron. ARCHIBALD ALLISON. H. F. & G. Witherby, Ltd., London, 1936. Cloth, 5¼ x 8 inches, 191 pages. Price 6s.

This book is a very interesting outline which will be read with value by the layman and the student of metallurgy. It is obvious that the treatment must be brief, but the author has prepared a bibiliography of books for reference. Unfortunately he has omitted the names of the publishers which does not make the list of much value outside the large reference libraries. This list is also limited to books in the English language, and even here no mention is made of: Spring—Non-Technical Chats on Iron and Steel, 2nd Edition, 1927, Frederick A. Stokes Co., New York; Walker—The Story of Steel, 1926, Harper & Bros., New York; and Wilhelm—The Book of Metals, 1932, Harper & Bros., New York.

The book has many interesting historical references and illustrations.

Richard Rimbach (15b) -B-

CURRENT NEWS ITEMS

A Correction—Nickel Steels at Low Temperatures

To the Editor: In the July issue of your valuable magazine I believe that I have located an unfortunate error in the article on nickel steels at low temperatures, by Aldridge and Shepherd. In Fig. 16, on page 192, it would appear that the draftsman who drew this chart has interchanged the numbers 4 and 6 in marking the curves for reference to the table at the top of the chart. As reproduced in Metals and Alloys, the figure indicates that the unalloyed carbon steel plate showed very good resistance to impact at low temperatures and that the nickel steel casting was very poor in this respect, whereas the contrary is actually the case.

Since it is quite possible that many readers may glance at this chart without carefully reading the text, it would appear to the writer that it would be well to point this error out in a future edition in order to avoid any misunderstanding.

A Beryllium Non-Ferrous Foundry

The Beryllium Corp. of Pennsylvania, Reading, Pa., announces the opening of a non-ferrous foundry department specializing in the production of heat-treated castings of beryllium alloys. Present facilities will take care of both large and small castings for electrical parts, machine parts and dies of beryllium copper, and other special alloys. Special foundry technique has been developed to make possible the best combinations of properties for these heat-treatable non-ferrous alloys.

Alloy Steels Simplified

A new publication, entitled "Alloy Steels Simplified," has been issued by the Carpenter Steel Co., Reading, Pa. Recognizing that the market for automotive alloy steels divides itself into two classes: The large tonnage buyers and the small tonnage buyers, the company has felt that buyers in the second class have been much confused by the multiplicity of structural alloys recently developed.

The purpose of this attractive and excellently conceived pamphlet is to simplify the alloy steels as far as possible and still cover the complete requirements of the small buyer. The publication is a valuable help and can be obtained free of charge to users of alloy steels in the United States.

Electrochemical Society's October Meeting

The Electrochemical Society will hold its 70th convention at the General Brock Hotel, overlooking Niagara Falls, Canada, Oct. 8 to 10. The general subject of the convention will be electrochemical products produced through the use of high temperature electric furnaces. "Power for Electric Furnaces" will be a feature symposium. A second session will be devoted to "What the Electric Furnace Has Done for Civilization," organized under the direction of F. J. Vosburgh of the National Carbon Co., New York.

Exhibit of Metals and Minerals

The American Institute of Mining and Metallurgical Engineers, in cooperation with the Metal Products Exhibits, Inc., has assembled an interesting and instructive exhibition which reveals the metallic elements present in the earth's crust, their availability, the locations of commercial sources and the flow of metals and minerals in world trade. Genuine ores, metals, and typical fabricated metal products, including specimens and displays supplied by State and Federal agencies as well as the major metal producing companies, are being shown.

This special exposition is open from Aug. 17 to Oct. 17 at the Metal Products Exhibits in the International Building at Rockefeller Center. It is open every weekday from 10 a.m. to 6 p.m. except Saturday, when the closing hour is 3 p.m. Admission is free.

"Clinics" on Welding Practice for Non-Ferrous Alloys

Latest developments in welding practice for non-ferrous alloys will be demonstrated at two "clinics" to be held in Cleveland and Buffalo, N. Y., during September. Included will be practical examples and demonstrations of the latest methods of electric and oxy-acetylene welding and brazing on Monel, aluminum, nickel, copper, brass, bronze, Inconel, and nickel-clad steel.

The "clinic" at Cleveland will be conducted by welding engineers of the International Nickel Co., the Aluminum Co. of America, and the Revere Copper & Brass Co. It will be held in the warehouse of Williams & Co., Inc., 1748-56 East 22nd St., on Sept. 18 and 19.

At Buffalo, the clinic will be held on Sept. 25 and 26 in the warehouse of Whitehead Metal Products Co. of New York, Inc., 254 Court St. It will be under the auspices of the International Nickel Co., the Aluminum Co. of America, and the American Brass Co. Somewhat similar clinics have been planned for Montreal and Toronto in October.

Technical Features of the Metal Show

Fifty-seven lectures and papers, dealing with every important phase of metallurgical engineering, will be presented during the technical sessions of the eighteenth annual convention of the American Society for Metals, to be held in Cleveland, Oct. 19 through 23, as a part of the National Metal Show. This announcement has been made by Robert S. Archer, president of the society and chief metallurgist in the Chicago district for Republic Steel Corp.

"This program gives the society the largest and most comprehensive list of talks ever scheduled, exceeding even last year's technical sessions. Papers will be presented each morning and afternoon of the convention, with the exception of Wednesday morning, when the society's annual meeting will be held and the 1936 Edward De Mille Campbell Memorial Lecture presented by J. P. Gill, chief metallurgist of the Vanadium Alloys Steel Co.

"The large number of papers to be presented at the 1936 convention again makes necessary the staging of simultaneous sessions," Mr. Archer continued. However, these have been arranged so that there will be no conflict with regard to subjects. In other words, no papers on the same subject will be presented at the same time and members will be able to hear all important lectures relating to their particular branch of the metal industry. There will be simultaneous sessions Tuesday, Thursday and Friday mornings and Thursday and Friday afternoons.

"Other features of this year's technical program are the lectures on 'Physical Testing of Metals' by Prof. H. D. Churchill, professor of mechanics at Case School of Applied Science, and the three lectures on X-Ray by Dr. Kent R. VanHorn, metallurgist of the Aluminum Co. of America."

Research Associates at Battelle

Clyde E. Williams, director, Battelle Memorial Institute, has announced the appointment of four research associates at Battelle for 1936-1937. The research associate plan, which is designed to supplement the work of the institute in fundamental research, is new this year. It is expected that a number of additional associates will be available in the future. Alfred Clark, Ph.D., University of Illinois, 1935, has been assigned a research project dealing with fundamental problems in chemistry; John E. Dorn, Ph.D., University of Minnesota, 1936, in metallurgy; Robert P. Graham, M.S., University of Washington, 1936, in ceramics; and L. G. Turnbull, Ph.D., University of Toronto, 1936, in industrial physics.

Elmer A. Schneider, formerly owner of the Mishawaka Pyrometer Instrument Co., is now production manager for **Wheelco Instruments Co.,** 1112 Milwaukee Ave., Chicago. Mr. Schneider was formerly with Leeds & Northup, and later with the Brown Instrument Co. and the pyrometric division of the Republic Flow Meter Co. **George W. Keller,** formerly vice-president of the Brown Instrument Co., is now in charge of the Eastern Sales Division of the Wheelco company.

MANUFACTURERS' LITERATURE

Chapmanizing

A pamphlet devoted to Chapmanizing, which is a process of hardening low-carbon steel, compares it to nitriding and carburizing. The Chapman Valve Mfg. Co., Indian Orchard, Mass. (936)

Air Operated Control Instruments

A colorful pamphlet devoted to the Air-O-Line controllers contains the statement that engineers like it because it insures maximum accuracy; it is easily adapted to any process control requirement as the throttling range and automatic reset dials are easily accessible and can be reached without removing the chart plate and taking the instrument off control; the balanced bellows system insures exact control point setting; and it is rugged. Illustrated. Brown Instrument Co., Philadelphia, Pa. (937)

Hi-Steel

Information concerning chemical composition, physical properties and corrosion resistance of this steel is offered by the Inland Steel Company, Chicago, Ill. (938)

Truck Body Construction

Through the use of the light, strong alloys of Alcoa Aluminum, bodies have been built which weigh only 35 to 60 per cent as much as they would have if built of heavier structural materials, according to this catalog. A table of recommended alloys for different applications is included. The alloys are available in the form of structural shapes, sheet plate, rivets, bolts, nuts, castings and forgings. Aluminum Co. of America, Pittsburgh, Pa. (939)

Insulation

Some looseleaf pages devoted to Therm-O-flake granules, a mineral insulator; Therm-O-flake coating, a high temperature insulation, Therm-O-flake light weight insulating brick and Therm-O-flake light weight concrete or castable insulation have been issued by the Illinois Clay Products Co., Joliet, Ill. (940)

Gas Fired Furnace

The manufacturer of the gas fired Lindberg Cyclone furnace for heating at temperatures from 250 deg. F. to 1400 deg. F. claims that the heating rate is remarkably fast, and either open or extremely dense charges are handled with equal facility. The principle of the furnace is described in Bulletin 51. Illustrations. Lindberg Engineering Co., Chicago, Ill. (941)

Flame-Otrol

This automatic gas shut off which is simple, positive in operation and operates with split second speed, according to the manufacturers, is the subject of an illustrated pamphlet. Wheelco Instruments Co., Chicago, Ill. (942)

Wheelabrator Tum-Blast Cleaner

This cleaner, which it is claimed sets the highest standard of efficiency ever attained in an abrasive cleaning machine is a combination of the Tum-Blast Cleaner and the Wheelabrator. Book 111 is devoted to it. American Foundry Equipment Co., Mishawaka, Ind. (943)

Controlled Atmosphere Electric Furnaces

This booklet lists advantages to be derived by the use of these furnaces and contains many illustrations of typical installations for annealing or normalizing without oxidation, for hardening without scale and for electric-furnace brazing. General Electric Co., Schenectady, N. Y. (944)

Konik

Data on this steel's physical properties, corrosion resistance and working are offered by the Continental Steel Corp., Kokomo, Ind. (945)

Sonittep Products

This booklet discusses heat loss and its control. The advantage of Sonittep insulating cement and its uses are listed. Instructions for its application are included. Graphs. George F. Pettinos, Inc., Philadelphia, Pa. (946)

Sixteen Sins of the Cleaning Room

Are listed in a circular for convenience in checking on cleaning rooms. Great Lakes Foundry Sand Co., Detroit, Mich. (947)

Armco H.T.-50

An illustrated folder devoted to the above alloy steel contains data on the average physical properties, corrosion resistance and forming and welding qualities. American Rolling Mill Co., Middletown, O. (948)

Heavy Duty Refractories

This handbook contains complete descriptions, applications, tables and illustrations of standard shapes. Many useful engineering data are included. Norton Company, Worcester, Mass. (949)

Braze-Rite Furnace

This furnace, developed principally for brazing sintered carbide cutting tools, provides for localized heat to be applied only to the portion of the tool to be brazed. The sintered carbide blank to be brazed in place is merely laid onto the shank and after the proper heat has been obtained the blank is firmly pressed onto the shank —all controlled under a hydrogen atmosphere. Illustrated. Firth-Sterling Steel Co., McKeesport, Pa. (950)

Sicromo Steel

High temperature data sheets containing full information on this steel have been issued by The Timken Steel & Tube Co., Canton, O. (951)

Application of Heat to Core Baking

A profusely illustrated booklet containing information resulting from research on the subject has been published by the American Gas Association, New York, N. Y. (952)

Ferrocarbo

This material containing both silicon and carbon combined in the form of silicon carbide acts as a graphitizer or softener when added to cast iron. The compound is broken up and the Si and C react vigorously with the Fe with an exothermic effect when the Ferrocarbo comes in contact with the molten Fe. The manufacturer claims that when Ferrocarbo is used with a properly adjusted charge, the fine graphite structure and high strength characteristic of a hard charge are combined with a high degree of machinability. Carborundum Co., Niagara Falls, N. Y. (953)

Drop Forgings

Characteristics, qualities and uses of drop forgings are discussed in an attractive book published by the Drop Forging Assn., Cleveland, O. (954)

Free Cutting Steel

An attractive booklet records fifteen years spent by the company's metallurgical department in research on the machinability of free cutting steels. Jones & Laughlin Steel Corp., Pittsburgh, Pa. (955)

Vanadium Facts

Another issue of this publication contains accounts of progress and performance in the field of alloy steels. Vanadium Corp. of America, New York, N. Y. (956)

Monel Metal and Nickel

Bulletin C-4 is devoted to the use of these metals in the manufacture of pharmaceuticals, fine chemicals and proprietary products. International Nickel Co., Inc., New York, N. Y. (957)

Fluxing, Deoxidizing and Hardening Alloys

Ajax alloys (phosphor copper, phosphor tin, nickel copper, manganese copper and silicon copper) are the subjects of a new leaflet issued by the Ajax Metal Co., Philadelphia, Pa. (958)

Sand Control in the Foundry

A colorful pamphlet lists the major causes of casting defects and inferiorities and states that they may be avoided by the use of the proper sand control equipment. Illustrated. Harry W. Dietert Co., Detroit, Mich.

Published by the same company: "The Core Maker"—a leaflet and "Deformation and Resilience Accessory for Universal Sand Strength Machine" —looseleaf data sheet. (959)

Value of Draft Control

Bulletin No. L-125 is devoted to the above subject and points out the proper value of the furnace draft and this company's control which consists of a draft switch, a damper motor and a manual station Illustrated. Shallcross Controls, Inc., Milwaukee, Wis. (960)

Spectrometric Equipment

Catalog D-221 is devoted to the above equipment. Basic theory and design are described as well as the various types of instruments. Illustrated. Bausch & Lomb Optical Co., Rochester, N. Y. (961)

What Scientists Say of Leitz Ultropak

Bulletin No. 17 describes the personal experiences and applications to which Ultropak has been placed by scientific workers in various fields. E. Leitz, Inc., New York, N. Y. (962)

Granite City Hi-Yield 1 and 2

This company offers two types of high elastic steel which may be ordered in the regular or corrosion resistant grade. These steels are recommended for use where abrasion resistance is required. Physical properties and a typical analysis are included. Granite City Steel Co., Granite City, Ill. (963)

Mallory Elkon

Looseleaf catalog containing engineering data with descriptions, illustrations and recommendations for the selection of electrical contacts for all types of service. P. R. Mallory & Co., Inc., Indianapolis, Ind. (964)

MANUFACTURERS' LITERATURE

Enduro

Data on the welding of Enduro stainless steels are given in a colorful brochure. Electric arc, gas, spot and projection, seam, flash, atomic hydrogen welding and brazing and silver soldering are features of this discussion. A complete list of products is included. Illustrated. Republic Steel Corp., Massillon, O. (965)

High Temperature Insulation

For all types of heated equipment is the subject of an illustrated leaflet issued by Armstrong Cork Products Co., Lancaster, Pa. (966)

Silico-Manganese Spring Steel

Extreme care is taken in processing this steel to avoid imperfections, in rolling to obtain cold-shearing qualities and in controlling the uniformity of the structure to insure both high inherent fatigue resistance and uniform heat treating characteristics, according to the manufacturer. Illustrated. Bethlehem Steel Co., Bethlehem, Pa. (967)

Dowmetal Data Book

A new edition of this book, containing especially significant accomplishments since the last data book, in the sections Available Forms and Shop Practice, has been published by The Dow Chemical Co., Midland, Mich. (968)

Cutting Oils

A leaflet is devoted to the EFHCut series of oils. It is claimed that this series represents the best straight cutting oils obtainable, at a price which meets and beats competition. E. F. Houghton & Co., Philadelphia, Pa.. (969)

Electric Furnaces

A pamphlet describes the "Certain Curtain" furnace which was developed for heat treating at temperatures between 1850 and 2500 deg. F. C. I. Hayes, Inc., Providence, R. I. (970)

Electric Welding Products

Catalog No. 101 contains information on welding rods (recommended uses for the different types, physical properties, welding procedure, etc.); miscellaneous apparatus, and Wilson arc welding machines. Air Reduction Sales Co., New York, N. Y. (971)

Duraloy

Chrome-nickel and chrome-iron alloy groups with recommended applications are listed in a new pamphlet from this company. Centrifugal castings and recuperators are discussed and a table of the characteristics of various Duraloys is included. Illustrated. Duraloy Company, Pittsburgh, Pa. (972)

A. W. 70-90

This bulletin describes the new high-strength "70-90" steel in sheets and plates. An article on the engineering aspect of high-strength sheet steels is included. Alan Wood Steel Co., Conshohocken, Pa. (973)

Polishing Machines

A portable model and a floor model of these new metallographic machines are described and illustrated in a pamphlet from Eberbach & Son Co., Inc., Ann Arbor, Mich. (974)

Forging Rolls

Bulletin No. 91 claims that these wide adjustment forging rolls are completely modernized machines with improved mechanical operation, increased economy and efficiency of this forging method and improved quality of the product. They are built in six sizes which cover the field of forging that can be handled manually. Illustrated. Ajax Manufacturing Co., Cleveland, O. (975)

Industrial Furnaces

This catalog describes, illustrates and gives specifications for furnaces suitable for various applications. Mahr Manufacturing Co., Minneapolis, Minn. (976)

Zinc Alloy Die Castings

A technical booklet tells the story of the development of the "Zamak" alloys. Tables and illustrations. New Jersey Zinc Co., New York, N. Y. (977)

Phosphor Bronze

A leaflet lists the sizes in which the company's twelve-inch stock bushing bars are now offered. The Phosphor-Bronze Smelting Co., Philadelphia, Pa. (978)

Rocking Furnace

Type G-M is a small-scale indirect arc electric furnace designed for iron, steel, brass, copper and nickel alloy. The furnace is illustrated and specifications are included in a leaflet which has been prepared by the Detroit Electric Furnace Co., Detroit, Mich. (979)

Alloy Steels

A colorful folder devoted to these steels lists some of the advantages to be obtained by their use. Bliss & Laughlin, Inc., Harvey, Ill. (980)

Properties of OFHC Copper

An attractive booklet contains reprints of three papers relating to the above subject. Photographs, diagrams and photomicrographs are used to illustrate them. United States Metals Refining Co., New York, N. Y. (981)

Optical Pyrometer

The Burrell optical pyrometer, a direct reading instrument originally designed for use with the Barrett fusion furnace and equally useful for other work requiring an optical pyrometer with a temperature range from 1500 to 3000 deg. F., is described and illustrated in a leaflet published by the Burrell Technical Supply Co., Pittsburgh, Pa. (982)

Electromet Review

This publication, whose purpose is to bring "News and Views of Alloy Steels and Irons" to the reader, contains interesting items. Electro Metallurgical Co., New York, N. Y. (983)

Dolomite Refractories

This interesting pamphlet presents the case of Clinkered vs. Calcined Dolomite in the basic open-hearth steel furnace. Basic-Dolomite, Inc., Cleveland, O. (984)

Crucible Melting Furnaces

PDM Met-L-Melt furnaces for melting aluminum, brass, monel, nickel and iron, oil or gas fired, embody new design using the latest improved refractories, resulting in superior metal, low fuel consumption and melting speed, with long life of lining and crucibles, according to this company's Bulletin M-736. Philadelphia Drying Machinery Co., Philadelphia, Pa (985)

Aerocase

Booklet on this subject. Illustrations, curve charts, tables. American Cyanamid and Chemical Corp., New York, N. Y. (986)

Radium for Industrial Radiography

This article written by R. A. Gezelius and C. W. Briggs, containing interesting and important information on the subject, is published in handy booklet form. Radon Company, Inc., New York, N. Y. (987)

Special Atmospheres in the Heat Treatment and Brazing of Metals

A reprint of the above article by C. L. West, Research Engineer, is offered by The Electric Furnace Co., Salem, O. (988)

Inhibitor

Grasselli 3 inhibitor for efficient, economical pickling is the subject of a booklet of The Grasselli Chemical Co., Inc., Cleveland, O. (989)

Bimetal

A simplified version of its manufacture and the way it works is contained in this pamphlet. W. M. Chace Co., Detroit, Mich. (990)

Electric Arc Welding

The Manual for Training Operators contains very complete information on the subject. General information, theory of arc-welding, complete set of lessons and tests on the fundamentals of the metallic arc-welding process are some of the features. Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. (991)

Alloy Castings

Corrosion resistant and stainless steel castings are the subject of a new booklet. Chemical and metallurgical properties of these castings are included. Illustrated. Michiana Products Corp., Michigan City, Ind. (992)

Castings

Beryllium copper heat treated castings, either finished or unfinished, because of the fatigue, corrosion-resisting, high strength and unusually stable properties of this alloy, are offered to industry to fill the demand for better properties in cast parts, according to The Beryllium Corp. of Pa., Reading, Pa. (993)

Stainless and Heat Resisting Electrodes

A colorful price list and data book containing complete descriptions of the company's products and also analyses of stainless and heat resisting alloys manufactured by other companies has been issued by Maurath, Inc., Cleveland, O. (994)

3300 Deg. Super Refractory

An illustrated catalog devoted to "Shamva" Mullite contains information regarding its background, characteristics and uses. Mullite Refractories Co., Shelton, Conn. (995)

NEW EQUIPMENT AND MATERIALS

Korduct Is New Thin-Wall Form of Transite Conduit

"Transite Korduct," a new thin-walled companion to "Transite Conduit," has just been announced by the Johns-Manville Corp., 22 East 40th St., New York, after several months of development work which included a number of successful field installations.

Korduct, identical with Transite Conduit except in thickness, is an asbestoc-cement product formed under high pressure on a polished steel mandrel which assures an absolutely smooth inner surface. Transite Conduit was created more than two years ago to provide a conduit sufficiently strong and resistant to enable the laying of underground duct systems without a concrete protective envelope, and also to provide permanence in an electrical conduit used in exposed locations.

Korduct has now been introduced in its thin-walled form to enable the economical application of Transite's permanence and other inherent qualities to duct systems that are enclosed in concrete. Korduct is rot-proof and incombustible. It is immune to electrolysis and highly resistant to all forms of corrosion. Its rate of heat dissipation is high and cables are easily pulled through its smooth interior. This new material is recommended for use on all multiple duct transmission systems, in tunnels, bridge structures or dams, and wherever the service calls for concreting in.

Johns-Manville has prepared a new brochure containing complete engineering and technical data on both Transite Conduit and Korduct.

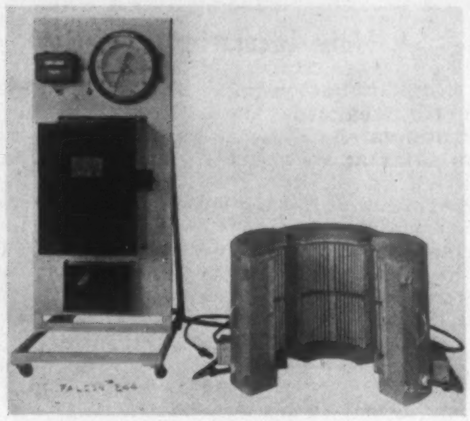
Another Falcon Electric Stress Reliever

Supplementing information which was published in the June, 1935, issue relative to "Falcon" portable electric heaters for stress relieving welded seams in pressure piping, nozzle attachments, etc., an additional type of "Falcon" heater now is being supplied to customers of H. O. Swoboda, Inc., Pittsburgh.

The heater is arranged in three sections for clamping together around the pipe to form a complete circular unit. This heater is suitable for pipe sizes 8 to 12 in. in dia. with maximum thickness of 1¼ in. The capacity of the heater is 27 kw. and it can be used on either 220 or 440 volts, 3 phase (one heater section per phase).

With the heaters are furnished portable automatic control panels for regulating and controlling the temperature during stress relieving and cooling. The control consists of contactor, transfer switch (for transferring to 220 or 440 volts or vice versa), push button, current input regulator for regulating the heating up and cooling off periods for various thicknesses of pipes and automatic recording control pyrometer for recording temperature and controlling same during stress relieving.

The heaters are provided with thermocouple location holes for inserting thermocouple for reading the temperature of the pipe at the weld during stress relieving. The heater is provided with plug type terminals; the control is supplied with 50 ft. length of flexible cable with plugs for connecting to heaters.



The heaters have a heating face of 22 in. in length to insure absolutely uniform stress relieving temperature in the pipe for a distance of six times the pipe thickness on each side of the weld and to allow the pipe temperature beyond said area to gradually diminish in order to eliminate the possibility of abrupt temperature differential between the hot and cold sections of the pipe.

Solvent Degreasing Machine

A new two-dip solvent degreasing machine, designated as size 624, has recently been added to the line of Detrex Degreasers manufactured by Detroit Rex Products Co., 13005 Hillview Ave., Detroit. Among the important features are a water jacket type of condenser completely encircling the machine, and a solvent condensate collecting trough located directly beneath the condenser. By this arrangement of the condenser and condensate collecting trough, the solvent vapors are held within the machine and all of the pure solvent distillate is emptied directly into the second or rinse chamber, thus continuously renewing the rinse chamber with pure solvent.

With this type of degreasing machine, the work is usually handled manually in baskets or on racks. For convenience, especially when comparatively heavy loads are cleaned, a small hoist may be employed. This machine is used for both immersion and vapor cleaning. The usual sequence of operations is to immerse the work in the boiling chamber, cool it in the clean solvent rinse, and finally suspend it for a few seconds in the pure solvent vapors over the boiling chamber. The work is removed clean and dry. This complete cycle of cleaning operations is accomplished in less than a minute and yet every trace of oil and grease is removed.

Either "Perm-A-Clor" or "Triad" stabilized chlorinated solvent is used in Detrex Degreasers. These solvents are non-inflammable and non-explosive and have a solubility factor for oils and greases more than four times that of ordinary organic solvents. The solvents are used over and over with but slight maintenance. The contamination resulting from the cleaning operation is removed from the solvent by periodic distillation within the machine. To facilitate this cleaning operation, there is an outlet from the solvent trough at one end. The unit is arranged for electric heating, using three immersion type heaters. These degreasers are also designed for steam or gas heating.

A Bright Zinc Deposit

A new and radically different type of zinc deposit, known as "Grasselli Bright Zinc," is announced by the Grasselli Chemical Co., Cleveland. In contrast to the old electro-galvanizing, in which in most cases the deposits of zinc were dull, gray and porous, this new process deposits zinc in a very brilliant, dense and ductile form.

The primary function of zinc deposits is to protect the underlying steel or iron from rust and corrosion. A rough porous coating which will hold moisture and easily collect dirt and foreign materials, especially microscopically small metallic particles, will discolor and deteriorate more rapidly than a dense, smooth plate, and, consequently, afford less protection against rusting and corrosion of the base metal than an impervious smooth deposit.

While appearance is often of secondary consideration, it is becoming more and more necessary to provide products with eye appeal. This is what Grasselli Bright Zinc does. It produces a very ornamental finish. Thus, one objection to zinc plating that has in the past ranked it inferior in the class of electro-deposited finishes has been overcome, and, at the same time, its value from a standpoint of rust prevention has been increased.

These improvements in the electro-deposition of zinc are largely the result of the use of molybdenum, a recent development of the same company. The use of molybdenum in the electro-deposition of zinc may parallel its use in stainless and alloy steels. In contrast to the old methods of electro-galvanizing, this new process operates at normal room temperatures, higher current efficiencies, high or low current densities, with a bright plating range from 15-100 amps. per sq. ft., and provides unusual economies.

Enamels To Protect Steel from Corrosion

A new line of air-drying enamels, especially designed to prevent the corrosion of iron and steel in railroad, marine, mining, oil, and general industrial service, has been developed by Maas & Waldstein Co., makers of lacquers and lacquer enamels, Newark, N. J.

These new anti-corrosive enamels are made of rust inhibiting pigments and a synthetic resin vehicle, and form a hard, tough coating that is resistant to wear and of pleasing appearance. Exposure tests, conducted for a long period of time, show that they are particularly effective in providing protection from the corrosive action of humidity, salt water, alkali, and a variety of chemicals, and in preventing electrolytic action, according to the manufacturer. A single coat gives adequate protection where the exposure is not prolonged or severe, but for maximum protection two coats are recommended.

These new enamels can be applied by either brush or spray. They air-dry in 4 hours, and are hard overnight. Types for baking for 1 hr. at 250 to 350 deg. F. can also be supplied. They cover approximately 350 ft. per thinned gallon. Available colors are brown, black, red, and a bronze liquid, which serves as a vehicle for aluminum and other metallic powders.

Electrolytic Production of Metallic Manganese

The first report of the electrometallurgical laboratory of the Bureau of Mines, Department of the Interior, soon to be issued, will disclose the development of a method for the production of metallic manganese from its ores by leaching and electrolysis. The pure metal so produced is in the form of bright, coherent sheets perfectly stable in air. The electrolyte used is manganese sulphate, since this is the most convenient form in which to obtain manganese by leaching. The secret of success is an ingenious method of maintaining an absolutely constant acidity of the electrolyte. The process is simple and cheap and adaptable to commercial utilization.

It is estimated that the power requirements for electrolytic precipitation will not be more than 4,000 kw.-hr. per ton of manganese. With large manganese deposits located within reach of power from Boulder Dam and other Federal projects, the power cost of producing high-purity manganese metal from the sulphate electrolyte obtained by leaching may be as low as $10 a ton.

A New Insulating Material

Consummation of a selling arrangement whereby the Armstrong Cork Products Co., Lancaster, Pa., will act as sales agents in the equipment insulation field for the Corning Glass Works' new highly refined wool insulation consisting of long, interlocked glass fibres, is announced by L. E. Cover, manager of Armstrong's equipment insulation sales department. Armstrong will sell this efficient material under the trade name of "Armstrong's Wool Insulation" and it will be furnished in the form of sealed packages, blankets, fold-bats, and in bulk or loose form for use as a fill insulation.

Included in the field to be served by Armstrong will be manufacturers of refrigerators and refrigerated equipment, refrigerator and passenger railway cars, refrigerated truck bodies and passenger automobiles, stoves, and equipment for the oil, steel, and other industries. The material also will be sold by Armstrong for industrial duct insulation and other industrial equipment.

Tests made by the Armstrong research laboratories show that the insulating wool, made by Corning Glass Works, possesses unusually low thermal conductivity, ranging, in the commercial densities, from 0.23 B. t. u. to 0.26 B. t. u. hr. deg. F. at 90 deg. F. mean temperature. Especially long, intertwined fibres give the insulating wool blankets strength. Since the insulation holds together, it will not shake down or settle under extreme vibration. Depending on the temperature requirements the new wool insulation can be furnished in forms weighing from 1½ to 6 lbs. per cu. ft.

New Brazing Alloy Increases Applications

Improvements and refinements in manufacturing "Phos-Copper" brazing alloy have been announced by the Westinghouse Electric & Mfg. Co. Increasing its field of application, the new processes include annealing and pickling to insure freedom of any carbonaceous deposit on the surface which might interfere with the production of leak-proof joints. This makes the new alloy especially suitable for applications such as refrigerator parts where leak-proof joints are a necessity.

An alloy of phosphorus and copper developed to replace expensive silver solders, Phos-Copper has a relatively low melting point, high tensile strength and excellent penetration. Some of its other desirable properties include absolute uniformity of alloy, self fluxing properties for most applications, high ductility, high fatigue resistance, high corrosion resistance, high electrical conductivity, high fluidity at brazing temperature, and economical to use. Also, brazed joints may be electroplated or tinned.

Phos-Copper is available in many sizes and shapes, including rod, ribbon, washers, strip, and other shapes. Standard rods are 3 ft. in length with diameters as follows: 1/16, 3/32, 1/8, 3/16 and 1/4 in. Ribbon is 0.015 in. thick by 1.25 in. wide. Other shapes for special applications are available.

It is applicable to all kinds of copper and copper alloy joints where strength, or gas and liquid tight joints are required, such as bus bar structures, copper tanks, cooling coils, electrical connections radiators, refrigerators, terminal lugs, water heaters, copper piping, air conditioning systems, and copper smithing.

Phos-Copper is applied essentially the same as soft solders, except that it requires a higher temperature. It melts at 707 deg. C., a temperature which can easily be obtained by an oxy-acetylene torch, incandescent brazing or carbon arc. High fluidity at brazing temperatures makes the alloy easy to use. At brazing temperatures it flows freely over the surface, facilitating the brazing of hard-to-get-at joints. It is self fluxing when used on ordinary copper work where it is not necessary to secure gas or liquid tight joints.

Parker Launches Zinc Bonderizing Process

Working behind closed doors, research workers of the Parker Rust Proof Co. in Detroit have been testing, experimenting and retesting a new Parker process. They have just made the announcement that they have perfected a new process and are satisfied with their tests. The new process is called Bonderite "Z." This latest Parker process is claimed to prevent corrosion and to stabilize paint finishes on zinc-alloy die-castings and galvanized and galvanealed iron. Like the other now famous Parker processes, it is a low-cost, easily applied, chemical conversion process that both coats and alters the surface of the metal.

Metallurgists, designers, sales engineers and executives who have seen the results of tests with the new Bonderite "Z" process are reported to unite in agreeing that it will open the door to new sales opportunities and new markets for many manufacturers, such as producers of zinc die-castings. These require little or no machining and finishing, can be more easily cast into intricate shapes, and usually can be produced in quantities more economically. Galvanized and galvanealed iron, too, have long been considered the ideal materials for countless stampings, linings and other parts or products that are to be subjected to long and hard use.

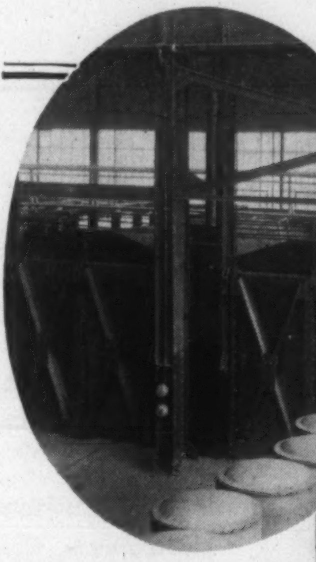
Nevertheless, these materials have been kept out of some markets because of corrosion difficulties and poor paint-holding qualities. But now, with the development of the Bonderite "Z" process that prevents corrosion and gives them a substantial base for paint, zinc and galvanized iron can step into these markets. Bonderite "Z" is claimed to greatly extend their already wide sales fields.

Technically, Bonderite "Z" is a chemical conversion process. It converts the metal's smooth surface into an absorbent, paint-holding, crystalline structure and produces an insoluble phosphate salt coating that becomes an integral part of the metal itself. It may be applied to zinc-alloy die-castings, stampings, forgings and rolled or machined parts and galvanized or galvanealed parts of any size or shape. Its effectiveness is best demonstrated on parts having recesses, depressions or internal threads. It contacts all surfaces equally, converts the metal, and deposits its protective coating in every crevice and corner. Because it is a chemical conversion process, and because it is applied at comparatively low temperatures, Bonderite "Z" does not change the size, shape or contour nor does it distort or warp the production treated. Like Bonderite "B" and "X," and its other related processes Bonderite "Z," requires comparatively simple equipment, is easily applied, and is inexpensive. It requires no electric current. Besides ordinary cleaning and rinsing tanks, the only other equipment needed is a processing tank of sufficient size—and trays, baskets or hooks in sufficient quantity—to handle the daily production requirements.

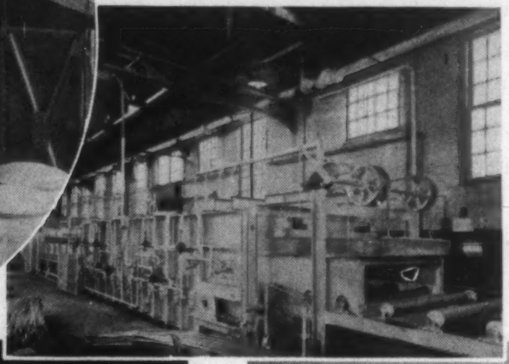
Bonderite "Z" can be applied without expert supervision. Parts to be treated are simply cleaned, immersed in the processing tank ½ to 3 min., removed, rinsed and dried. It comes in concentrated liquid form which requires only the addition of water to prepare the working solution. A simple titration indicates the concentration of the processing solution which can easily be kept at the proper working strength by the addition of the concentrated Bonderite "Z" chemical. The entire process, including chemicals, labor, and write-offs on equipment, adds but a fraction to the total cost of any product.

LEADING FURNACE BUILDERS INSULATE WITH ARMSTRONG'S BRICK

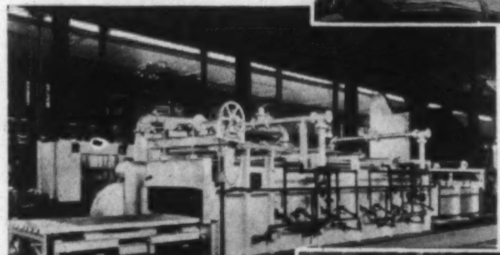
...to insure successful results

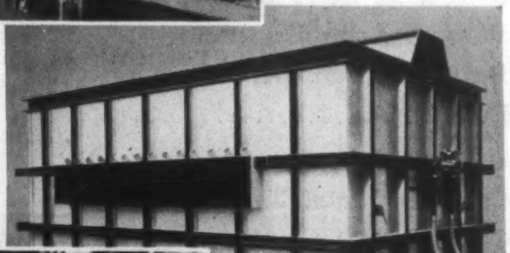


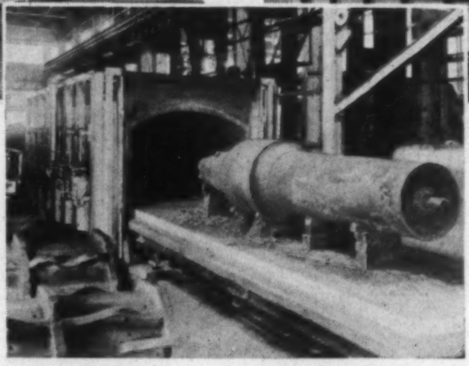
LEFT—
RUST *of Pittsburgh built a battery of these box annealing furnaces for the Wheeling Steel Corp., and insulated them throughout with Armstrong's N-16 Insulating Brick for accurate temperature control and operating economy.*



LEFT—
ROCKWELL *insulated this gas-fired, continuous, controlled atmosphere, brass annealing furnace with Armstrong's EF Insulating Fire Brick. The result is efficient operation with uniform temperatures.*







ABOVE—
SURFACE COMBUSTION *knows the value of efficient insulation to prevent waste of heat. That's why this normalizing furnace, like many others built by this Toledo Company, is insulated with Armstrong's High Temperature Products.*

SWINDELL-DRESSLER *report fuel savings of 65% with this gas-fired, car-type annealing furnace which they built for a Pittsburgh manufacturer. Insulation is 9" Armstrong's EF-22 Insulating Fire Brick backed up with 9" Armstrong's N-16 Insulating Brick.*

ABOVE—
LEE-WILSON, *furnace builders of Cleveland, Ohio, insure uniform distribution of heat in this vertical-tube annealing cover by insulating it with Armstrong's N-20 Insulating Brick.*

ARMSTRONG'S High Temperature Products have won the preference of leading furnace manufacturers and plant operators for two big reasons. *First*, the technical expertness with which they are made. *Second*, the careful testing which keeps them consistently up to Armstrong's rigid specifications for quality.

The complete line of these time-proven products includes: Armstrong's N-16, N-20, and A-25 Insulating Brick for temperatures up to 1600°, 2000°, and 2500° F., respectively, behind the refractory; and Armstrong's EF-22 and EF-26 Insulating Fire Brick for use without fire brick protection up to 2200° and 2600° F., respectively.

We'd like to send you your copy of the new illustrated folder on Armstrong's High Temperature Products, without obligation. Write Armstrong Cork Products Company, Building Materials Division, 982 Concord Street, Lancaster, Pennsylvania.

At the Heart of the Car—MOLY Iron

Modern, more efficient automotive engines require modern, more dependable materials. From the cylinder block to the smallest washer, dependability is the first consideration.

Moly cast iron makes it possible to meet the strictest cylinder block requirements economically. Sections can be as thin as necessary, and still have the requisite strength. The structure of Moly iron is stable at operating temperatures. Wear resistance is excellent, and hardness is uniform regardless of section. Consequently the dependability of the block is high—and its life is longer.

Moly blocks are economical to cast and finish. There are fewer rejects from casting flaws. Fine grain makes it easier to lap bores and bearing bushings to a high polish.

These are the highlights of Moly iron. Fuller details are given in our technical book, "Molybdenum"—yours for the asking. The service and experience of our laboratory are always available to those interested in investigating Moly as a solution for their ferrous problems.

1. ORE CONCENTRATION

JOHN ATTWOOD, SECTION EDITOR

Gold Ore from Island Mountain, Wells, Cariboo District, B. C. W. B. Timm et al. *Canada Department of Mines, Mines Branch, Report* No. 748, 1936, pages 6-15. Amalgamation failed to recover Au; jigging effected no concentration. Flotation of an 0.84 oz. ore gave a 3.08 oz. concentrate at 88% recovery. Cyanidation extracted up to 97%. **Gold-Silver Ore from Kozak Mine, Algoma District, Ontario.** Pages 16-20. Maximum recovery is secured by flotation at 90% —200 mesh. Cyanidation gives a higher Au recovery but Ag losses are much higher. **Gold Ore from Bosquet Gold Mines, Limited, Sudbury, Ontario.** Pages 21-28. Good recovery can be obtained by any one of a number of standard flow sheets. **Gold Ore from Bluenose Gold Mining Company, Limited, Stormont Township, Guysborough County, N. S.** *Ibid.*, pages 29-37. For a small mill, stamp to 35 mesh, amalgamate, table the tailings, discard sand, thicken and float slimes. Amalgamation recovers 71.25% of the Au, tabling 11.75% and flotation 15.7%; recovery after extraction is 95%. For a large plant, ball mill to 60% —200 mesh, amalgamate and cyanide tailings. Overall recovery is over 95%. **Gold Ore from the Canadian Malartic Mines, Limited, Abitibi County, Quebec.** Pages 38-45. Working with an ore assaying 0.22 oz. Au/ton, low recoveries were obtained by amalgamation or flotation alone or in combination with traps, blankets or amalgamation plates. Cyanidation of 50-60% —200 mesh pulp gives 88-90% extraction. **Gold Ore from Stadacona Rouyn Mines, Limited, Rouyn Township, Témiscaminque County, Quebec.** Pages 46-49. Maximum recoveries (95%) are obtained by cyanidation of —150 mesh ore for 48 hrs. **Gold Ore from Rice Lake Gold Mines, Limited, Manitoba.** Pages 50-52. From 60 to 70% of the Au is recovered by amalgamation; 97% is extracted by 48 hrs. cyanidation of —150 mesh ore. Grinding, discharge over a blanket, amalgamation of the concentrate and thickening and cyanidation of the tailings is recommended. **Gold Ore from the Queen Mine, Sheep Creek Gold Mines, Limited, Salmo, B. C.** Pages 53-60. Tests by amalgamation, flotation and cyanidation in various combinations are reported. Fine grinding is necessary. Cyanidation, giving 98% extraction, is the most satisfactory. **Arsenical Gold Ore from Minto Gold Mines, Limited, Bridge River District, British Columbia.** Pages 61-71. Straight cyanidation or concentration by flotation and blanketing with smelting of the concentrates gave 85-90% recovery. **Gold Ore from Grandoro Mines, Limited, Penticton, B. C.** Pages 72-76. Amalgamation recovered 75%. Cyanidation at 45% —200 mesh for 24 hrs. gave 97.5% extraction with low reagent consumption. Flotation recovered 97.32% of the Au, but overall recovery after cyanidation of the concentrate was 81%. **Ore from Central Patricia Mines, Limited, at Pickle Lake, Ontario.** Pages 77-80. Pyrrhotite in the ore greatly reduces cyanide extraction. Grinding in alkaline solution, followed by aeration for 6-8 hrs., gives 92-96% extraction. **Gold Ore from the Porcupine Peninsular Gold Mines, Limited, Timmins, Ontario.** Pages 81-86. Maximum recoveries are obtained by 48 hrs. cyanidation of 93% —200 mesh ore. Flotation of 44% (or 95%) —200 mesh ore recovers 90% of the Au; cyanidation of reground concentrate gives 83% overall recovery. **Ore from the Wendigo Mine, Near Kenora, Ontario.** Pages 87-94. Cyanidation is unsuitable due to high Cu content. At 60% —200 mesh, over 70% of the Au is caught on blankets and 20% recovered in a flotation concentrate assaying 20% Cu and 2-2.5 oz. Au. Plate amalgamation recovers 60% and flotation 30% more. **Ore from the Kilo Mine, Near Slocan City, B. C.** Pages 95-105. From 85-98% of the Au is recovered on blankets. Amalgamation of the concentrate after 93% extraction gives a minimum recovery of 79%. Use of amalgam plates with the blankets gives overall recovery of about 90%. Recovery can be increased by treatment of the 4-oz. tailing. Cyanide extraction was 95%. **Ore from the Arntfield Gold Mine, at Arntfield, Quebec.** Pages 106-110. Cyanidation, perhaps with tabling and regrinding of the sulphides, is the most practical; over 95% extraction is obtained. **Gold Ore from Pontiac-Rouyn Gold Mines, Limited, Rouyn Township, Quebec.** Pages 111-116. Cyanidation of —200 mesh ore for 24 hrs. gave 93% extraction with low reagent consumption. Blanket concentration followed by flotation gave 93.5% recovery. **Gold Ore from God's Lake Gold Mines, Limited, God's Lake, Manitoba.** Pages 117-125. Cyanidation is satisfactory; there are certain advantages in using blankets, jigs or traps in closed circuit with the mill and classifier. **Gold-Silver-Lead Ore from the Marysville Mining Company, Limited, Fort Steele Mining Division, B. C.** Pages 126-133. The highly altered condition of the minerals makes concentration difficult; a 2-stage process is necessary. Tabling gives a concentrate containing galena and Au. The tailing, consisting largely of $PbCO_3$, requires sulphidizing prior to flotation. Cu is difficult to concentrate. About 90% of the Au and 80% of the Ag are recovered by tabling and flotation. **Gold-Copper Ore from Tashota Goldfields, Limited, Tashota, Ontario.** Pages 134-140. Blankets between the grinding mill and the classifier recover 50-65% of the Au; barrel amalgamation recovers 98% of the Au in this concentrate. Flotation of the tailing with depression of pyrrhotite and pyrite with lime, gives a concentrate containing 19% Cu and 2.69 oz. Au and a tailing assaying 0.075 oz. Au; this can be reduced to 0.01 oz. by cyanidation. Overall Au recovery is 97% and Ag 98%. **Copper-Gold Ore from the Sunset and Mother Lode Mines, Boundary District, B. C.** Pages 141-151. Ball milling to 75% —200 mesh, aeration of the classifier overflow for 20 min., rougher flotation, cleaning, and regrinding and return of the middling gave 90% Cu and 85% Au recovery in a 20% Cu and 0.80 oz. Au concentrate. **Gold Ore from the Reno Gold Mines, Limited, Salmo, B. C.** Pages 152-158. Amalgamation of a blanket concentrate gave 53.6% Au recovery; cyanidation gave 39-45% more. Very fine grinding was not beneficial. Pre-aeration will lessen the cyanide consumption by pyrrhotite. **Gold Ore from the Powell-Rouyn Gold Mines, Limited, Rouyn Township, Quebec.** Pages 159-164. Cyanidation preceded by trapping of coarse Au is most suitable. **Gold Ore from the Hudson-Patricia Gold Mines, Limited, Narrow Lake, Ontario.** Pages 165-170. Cyanidation extracts 98% of the Au; traps should be used. **Gold-Silver Ore from the Monashee Mines Syndicate, Limited, Vernon, B. C.** Pages 171-178. Cyanidation of ore ground 70-80% —200 mesh gives 96% extraction of Au and 83.4% extraction of Ag with normal reagent consumption. Barrel amalgamation of a blanket concentrate (100-130 oz. Au/ton) followed by flotation of the tailing gives an overall recovery of 94-95% of the Au and 90% of the Ag. **Arsenical Gold Ore from the Hedley Mascot Mine, Hedley, British Columbia.** Pages 179-190. Good results were obtained by cyanidation followed by flotation of the tailings. Due to the high As content, the concentrate can be sold to a smelter equipped to handle it, roasted and cyanided, or reground to —325 mesh and cyanided.

1a. Crushing, Grinding & Plant Handling

Heavy Fluid Separation—New Efforts Offer Promise. F. J. Tolonen. *Engineering & Mining Journal,* Vol. 137, Feb. 1936, pages 91-92. Recent development in the use of heavy liquids in the preparation of minerals has been in 2 general fields: (1) where the media are heavy liquid chemicals, or solutions having a high sp. gr., and (2) where they consist of suspensions of more or less finely divided solids in water. The flowsheet for one application to Fe ore and on Cu rock is shown. Heavy fluid processes may be used for preliminary enrichment of feed.
WHB (1a)

1c. Flotation

Critical Observations of Mineral Behavior When Associated with Superheated Water. Arthur J. Crowley. *Engineering & Mining Journal,* Vol. 137, Jan. 1936, pages 27-30. This phenomenon is believed to function importantly in the processes of mineral depositions. A S liquefier is described and illustrated that permits the production of a 99.5% S from 86% S flotation concentrate from Nevada ores. It seems likely that similar conditions have existed in the past in Nevada, Utah and California which may have caused the formation of the S deposits.
WHB (1c)

New Methods for Treating Gold Bearing Ores (Les nouvelles méthodes de traitement des minerais auriferes) Ch. Berthélot. *Revue de Métallurgie,* Vol. 33, May 1936, pages 291-294. The present general tendency in handling Au ores is to recover as much Au as possible in the first stages of the processes. Xanthates mixed with other collectors appear to be the most used. JDG (1c)

The Bubble Machine for Flotation Testing. Guido R. M. Giudice. *Engineering & Mining Journal,* Vol. 137, June 1936, pages 291-294. With a modification in construction and a changed technique of use, the results obtained with this machine in measuring contact angles are now readily reproducible. The bubble machine measures contact angles at the line of 3-phase contact: air or oil, mineral, and water. The arrangement of the apparatus is shown diagrammatically.
WHB (1c)

1d. Magnetic Separation

Experiments Upon Magnetic Dressing of Brown Hematite Ores of Lower Silesia (Versuche zur magnetischen Aufbereitung von niederschlesischem Kaseneisenerz) W. Luyken & L. Kraeber. *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Düsseldorf, Vol. 18, No. 4, 1936, pages 35-41. Experiments are reported to find means for concentrating high SiO_2 ores to reduce the great amount of lime additions necessitated by this condition and the consequently large amount of slag. Magnetic separation of part of the SiO_2 which occurs in form of small quartz grains was possible, but this yielded a concentrate of only 39.2% Fe with a total yield of Fe of 83%. After roasting the ore to ferromagnetic Fe oxide, however, a concentrate of 49.7% Fe with a yield of 83.3% Fe could be obtained, and this was still further improved, by crushing the intermediate sized grain, to 50% concentrate and yield of 88.7% of the total Fe. Under the existing conditions, magnetic concentration can be recommended for the Fe-poor parts of the ore while the richer ores may be dried only. The influence of grain size is shown by test runs.

The Oxygen Content of Cyanide Solutions. F. J. Tromp & W. E. Schilz. *Journal Chemical, Metallurgical & Mining Society of South Africa,* Vol. 36, Jan. 1936, pages 195-197. Discussion. See *Metals & Alloys,* Vol. 6, Nov. 1935, page MA 434L/7.
AHE (1e)

The Re-treatment of Cyanide Tailings from the Golden Horseshoe Mine. T. B. Stevens. *Bulletin Institution of Mining & Metallurgy,* No. 378, Apr. 1936, 12 pages. The tailings are sluiced by a monitor using spent solution and pulp. Recirculating a percentage of pulp makes use of a thickener unnecessary. Most soluble Au is dissolved in the sluicing circuit, so little agitator capacity is needed. In the agitators, cyanide concentration is 0.015%, derived from the spent solution; before precipitation it is brought up to 0.03%. Consumption of cyanide is 0.54 lb./ton treated. Solutions must be kept nearly neutral to prevent precipitation of Mg salts in the precipitation plant. Lime consumption is 1.2 lb./ton. Bullion contains Au 62, Ag 33 and base metals 5%. The plant is described.
AHE (1e)

The Solubilities and Free Energies of Some Metallic Sulfides. S. Frederick Ravitz. *Journal of Physical Chemistry,* Vol. 40, Jan. 1936, pages 61-70. The values recommended for the standard free energies of formation, the solubility products and the solubilities in H_2O of the metallic sulphides are given. 33 references.
EF (1e)

2. ORE REDUCTION

A. H. EMERY, SECTION EDITOR

Thermodynamic Approximation Calculations (Thermodynamische Näherungsrechnungen) Paul Drossbach. *Metall und Erz,* Vol. 33, Apr. 1936, pages 173-177. The approximation equation $\Delta Z = Q_1 - T\Delta S$, is discussed, and its application to several examples illustrated, among them the decomposition potential of Pb chloride and lime, and the reduction of Zn oxide and Fe oxide. FPP (2)

2a. Non-Ferrous

Zinc and Lead Recovery from Shaft Furnaces Slags at Trail (British Colombia) (Récupération du zinc et du plomb des laitiers de hauts-fourneaux à Trail (Colombie Britannique)) G. Murray. *Revue de Métallurgie,* Vol. 33, May 1936, pages 309-313. Abstract of a paper delivered at the 7th Congress of Mining & Metallurgy in Paris. Coal dust is blown into molten slag. C reduces oxides contained in it and excess of air oxidizes them into fumes which are recovered in gas houses. Daily recovery averages 100 tons. Full description is given in *Transactions of Canadian Institute of Mining & Metallurgy,* Vol. 34, 1933, pages 75-103. JDG (2a)

Making Alumina by the Seailles Process (La fabrication de l'alumine par les procédés Séailles) *Journal du Four Electrique,* Vol. 45, May 1936, pages 162-163. Al bearing materials are sintered at 1000°-1150° C. with $CaCO_3$ and leached with water. Leaching is feasible because at 30° C. calcium aluminates do not set. $CaCO_3$ and alumina are precipitated by CO_2. $CaCO_3$ can be removed from the mixture by treating with CO_2 charged water which removes Ca as bicarbonate. Or Al can be removed with soda. Anhydrous Al_2O_3 precipitates in the process, which permits utilization of siliceous bauxites, completely prevents soda losses and reduces expenses for heat generation and labor. JDG (2a)

Electrolysis of Aluminum Sulphide. E. I. Khazanov & A. I. Belyaev. *Legkie Metallui,* Vol. 4, Nov. 1935, pages 1-14. In Russian. Al_2S_3 was electrolyzed in a solution of 70% NaCl and 30% Na_3AlF_6 at 800° C. A maximum current efficiency of 55% was obtained. Addition of Al_2O_3 to the electrolyte did not influence the efficiency but the addition of FeS sharply reduced the efficiency. HWR (2a)

Beryllium. Robert Gadeau. *Aluminium & the Non-ferrous Review,* Vol. 1, May 1936, pages 353-360. See *Metals & Alloys,* Vol. 7, June 1936, page MA 279L/5. JCC (2a)

Mercury in Germany (Deutsches Quecksilber) E. Reitler. *Chemiker Zeitung,* Vol. 60, May 2, 1936, pages 365-367. Germany's position in the world's production and consumption of Hg is discussed, and the composition, occurrence and extraction of Hg ores, and current uses of the metal are described in some detail. FPP (2a)

2b. Ferrous

Overblowing in Blast Furnace Practice. Wm. McConnachie. *Blast Furnace & Steel Plant,* Vol. 24, May 1936, pages 403-405. Using data presented by J. Gayley in *Journal of the Iron & Steel Institute,* 1890, pt. 2, discusses reasons for increased fuel consumption when overblowing. Concludes that poor results must be attributed to the fact that extra blast has thrown more work on furnace, in that more crude Fe is reoxidized, and that proportionately more cyanide is oxidized, thus throwing a further amount of work on furnace, while simultaneously depriving it of a most useful reducing agent. Every effort should be made to utilize reducing power of the alkali cyanides to the fullest extent. This can be effected by abandoning idea of a more thorough distribution of blast by increasing number of tuyeres and realizing that a large proportion of stock does not pass through combustion zone, so must depend on deriving necessary heat in an indirect manner. It is advisable to keep number of air inlets down, and by overhanging tuyeres so to arrange for as great an area as is practicable in which the very powerful reducing vapors, generated below tuyere level, can rise among the materials without interference by the blast. This will permit greatest amount of O_2 removal, on which furnace pace depends, much more than on amount of heat produced, or on temperature attained in combustion spaces. MS (2b)

Speed of Dissociation of Carbon Monoxide in the Presence of Iron and Its Oxides (Sur la vitesse de dissociation de l'oxide de carbone en presence du fer et de ses oxydes) Francis Meunier. *Revue de Métallurgie,* Vol. 33, Apr. 1936, pages 258-264. Speed of decomposition of CO as a function of temperature and rate of flow was investigated. Traces of moisture badly affect equilibria, reaction taking place very rapidly. At all temperatures C precipitation drops very rapidly with the reduction of the time of contact. With the same speed of flow a sharply marked maximum occurs at about 500° C. at atmospheric pressure. There was total absence of C precipitation in passing CO over Fe_2O_3 at 350°-600° C. before elimination of 11.1% O. At the same temperature, precipitation with time is much slower than reduction. Dissociation is very fast as soon as all metal is reduced. The amount of Fe_2O_3 reduced is a direct function of C precipitated. JDG (2b)

Making Ferro-Alloys from Ores in Electric Arc Reduction Furnaces (Fabrication des alliages de fer en partant des minerais par emploi de fours de réduction à arc électrique) Alfred Karsten. *Revue de Métallurgie,* Vol. 33, May 1936, pages 345-347. A superficial description of furnaces and processes, mostly used in Russia. JDG (2b)

3. MELTING, REFINING AND CASTING

The Dumbarton Valve Works of Babcock & Wilcox, Limited. *Foundry Trade Journal,* Vol. 54, Feb. 6, 1936, pages 119-121, 130. The manufacture of boilers for high pressures introduced an entirely new set of factors, calling for the installation of special machines and plant as also for the evolution of a new range of boiler fittings, more particularly valves. To meet the new conditions radical departures had to be made alike in design, material and constructive methods. To insure the absolute uniformity of production, which is an essential, careful consideration was given to the design of jigs, fixtures and gages. The calorizing shop is a separate block of buildings, where a number of different processes are used for the impregnation of certain of the ferrous components with Al. In the non-ferrous foundry are produced bronze, gunmetal and Ni-alloy castings. The paper is well illustrated with pictures showing different parts of this plant. AIK (3)

3a. Non-Ferrous

G. L. CRAIG, SECTION EDITOR

The "Modifying" Phenomenon and Its Probable Relation to Properties of Non-Ferrous Alloys. C. H. Lorig & R. W. Dayton. *Transactions American Foundrymen's Association,* Vol. 7, Feb. 1936, pages 262-268. The adding of certain deoxidizers and degasifiers to alloys may lead to the destruction of crystal centers or to the creation of new centers, to the spontaneous crystallization of the alloys in the supercooled state or to normal crystallization, and finally to wide variations in the properties of a given alloy. Cast metals are particularly susceptible to the above mentioned modifying action when it occurs. The few isolated examples of non-ferrous alloys deliberately modified either with modifiers, by super-heating or by chill casting show the vast possibilities of utilizing the modifying action to good advantage. The "silicate-slime" or "slag cloud" hypothesis which states that minute inclusions of some types act as nuclei for crystallization was developed to explain graphite formation in cast Fe. The authors review the work of various investigators in both the ferrous and the non-ferrous fields and explain how the theories mentioned might be applied to non-ferrous cast alloys to explain why alloys which are sound, reasonably free from contaminating metallic elements and of good manufacture sometimes possess irregular, if not totally dissimilar properties. CEJ (3a)

GOING UP!

CORE oil prices are on the way up.

Vegetable oils in various combinations are practically always used as bases in the manufacture of core oil. These ingredients are subject to wide and costly price fluctuations.

That is particularly true now!

Great Lakes CoroiL is unlike other core oil. It is a petroleum derivative. Its price is not subject to wide and dangerous price fluctuations. And it's better core oil. Not new or untried, it is used in scores of foundries of every description.

In view of the menacing price situation, isn't it just good business to try out Great Lakes CoroiL in your own plant NOW?

Order a trial drum today.

C. H. HERTY, SECTION EDITOR

Casting of Cast Iron in Chill Molds under Pressure (La Coulèe de la Fonte en Coquille sous Pression) L. J. GOUTTIER. *Revue de Fonderie Moderne,* Vol. 30, June 25, 1936, pages 199-208. Die casting of cast Fe is discussed; molds, equipment and means for producing air pressure and applying the latter in correct manner are described at length, in particular the Wetherill process. Methods for die casting of Pb, Sn, Zn, Mg, Al and Cu are briefly reviewed. Ha (3b)

Production of Sound Castings. T. R. HARRIS. *Iron & Steel Industry,* Vol. 9, June 1936, pages 370-374. Author deals with the production of sound castings in a jobbing foundry. There are a number of factors which can be controlled. Design can be modified to give a more even distribution of metal and insure a more uniform cooling of the metal throughout. The metal can be kept within close limits by using pigs of known qualities together with domestic scrap. Sand control can be reduced to ordinary routine practice. All details should be tabulated to avoid costly experimenting in the future. CMS (3b)

Alloy Cast Irons. P. A. RUSSELL. *Foundry Trade Journal,* Vol. 54, Mar. 19, 1936, pages 227-230. A paper presented to the Lancashire branch of the Institute of British Foundrymen. Thomas and Ballay recently suggested that the term "special cast iron" should be applied to cast irons containing one or more of the following elements in excess of:—Ni 0.3, Cr 0.3, Cu 0.3, Ti 0.15, V 0.10, Mo 0.10, Si 5.0, and Mn 1.5%, and that the term "High-grade cast iron" be applied to irons produced by special processes which do not contain the above alloys. Author does not agree with these terms. Principles of alloying, heat-resisting cast irons, corrosion-resisting cast irons, high-strength cast irons, etc. are discussed. It is pointed out that mechanism of the deterioration of cast Fe under heat is due to following factors:—(1) spread of internal oxidation via the graphite flakes; (2) breakdown of pearlite, with consequent setting up of internal strains which weaken the Fe, cause cracks, and thereby assist the spread of oxidation; and (3) general weakness of Fe due to high temperature *per se.* Heat-resisting cast irons can be classified as follows in order of increasing heat-resisting value; (1) Cr or Ni-Cr pearlitic gray cast irons (Cr 0.3—1.5, Ni 0.5—2.0%); (2) Cr white cast irons (Cr 0.5—1.5%); (3) Silal (Si 5—6%); (4) austenitic cast Fe of the Ni-Resist type (Ni 14—16, Cu 6—7 and Cr 2—5%); (5) Nicrosilal austenitic cast Fe (Ni 18—20, Si 4.5—5.5, Cr 2—4%). HAUSFELD MELTING FURNACES

Economical and Easy to Operate

Burning gas or oil, Hausfeld Furnaces operate at about one third the fuel costs of more complicated equipment. Each furnace is a complete, independent unit, simple in design and ruggedly constructed. They are practically foolproof and trouble-free. Any employee can quickly learn to operate a Hausfeld Furnace.

They give great flexibility to the foundry and turn out ferrous and non-ferrous alloys of uniform quality and analysis.

Write for detailed information on comparative operating costs.

THE CAMPBELL-HAUSFELD COMPANY
200-220 Moore St. Harrison, Ohio

Developments in the Production of Malleable Castings. I, II, III. Composition of Malleable Iron Mixtures. IV, V. Melting Plants and Their Operation. H. H. Shepherd. *Iron & Steel Industry,* Vol. 9, Nov. 1935, pages 51-35; Dec. 1935, pages 90-93; Jan. 1936, pages 127-131; Feb. 1936, pages 167-171; Mar. 1936, pages 204-208; Apr. 1936, pages 245-248. Brief review of the developments and improvements of physical properties of malleable Fe castings. There seems to be a narrowing of the gap which exists between the physical properties of good quality malleable Fe and the modern high strength cast irons. Many malleable plants produce material with a tensile of 55,000 lbs./in.^{2} and 15 to 25% elongation. Part II. It is a fairly generally accepted view that to secure malleable castings, it is advisable to limit the amount of annealed scrap in the mixture. In the case of malleable made from cupola melting and without subsequent treatment of the molten metal more than 3 to 4% of scrap causes reductions in the elongation and yield values. Steel scrap may be added to the mixture. For successful steel mixture practice, superheated metal without excessive oxidation is necessary. Part III. Refined pig Fe is rarely used for the manufacture of malleable by processes other than the cupola process. For whiteheart malleable the Mn should never be less than the S and where maximum ductility combined with normal strength is required the Mn should be from 1.5-2 times the S. For blackheart malleable made in a cupola a Mn content of 2.5 times that of the S is recommended. The influence of Ti, Cr and V are also briefly discussed. Part IV. The history and developments of the methods of melting suitable Fe mixtures for the production of malleable castings embraces almost the entire history and development of the melting of metals. Practically all types of melting practice have been, and still are used in varying degrees of output, from the crucible to electric and rotary furnaces. Comments are made on the crucible, cupola and duplex methods of melting. Part V. Further comments are made on the triplex process, and hand fired, pulverized coal fired and oil fired air furnaces. The use of the open-hearth furnace is discussed. Electric melting is considered and efforts to equalize the overall costs of electric melting with those of other melting mediums have largely consisted of utilizing the advantage of being able to use cheaper materials to make up the charge. CEJ (3b)

Studies on Solidification and Contraction in Steel Castings—III—The Rate of Skin Formation. C. W. Briggs & R. A. Gezelius. *Transactions American Foundrymen's Association,* Vol. 7, Feb. 1936, pages 274-295. The factors that influence the velocity of solidification of a steel casting, and the rate at which the skin forms are discussed. Studies are made on shapes of varying volumes and also on shapes with varying surface area and a constant volume. The numerical values obtained were used to calculate constants and formulas of solidification and to evaluate the importance of the theoretical considerations. A summary of the points as brought forward in the paper is: (1) The rate of skin formation increases as the volume of the steel casting decreases. (2) The greater the surface area of a steel casting the faster is the rate of skin formation. (3) The velocity of solidification is a constant; i.e., at any definite time after pouring the volume of steel solidified/in.^{2} of mold surface is the same. (4) Variations in the ordinary used molding materials results in a little more than a perceptible change in the velocity of solidification. (5) The degree of superheat modifies the rates at which the skin forms. (6) Calculations of the rate of skin formation can be made and predicated in various sizes of sphere castings. CMS (3b)

Mechanically Strong Cast Iron (La Fonte résistante) Guy Hénon. *Revue de Fonderie Moderne,* Vol. 30, Feb. 25, 1936, pages 57-67. Properties and manufacture of cast Fe of high mechanical strength, 25 kg./mm.^{2} minimum shear strength and 550 kg./mm.^{2} minimum bending strength, of pearlitic cast Fe with an elastic modulus of 16,000 kg./mm.^{2}, of cast irons taking good polish, elimination of porosities, and of heat and wear resistant cast Fe are discussed and the effect of the content of Si, C, Mn, S, P on these properties described. The composition should be in general: C between 3-4% depending on the operating conditions of the cupola; the lower values are preferable; Mn 0.7—0.9%, S less than 0.10% or even 0.08%, P usually less than 0.3%, for pieces of easy pouring qualities, however, up to 0.6%; Si should be regulated by the thickness of the piece as follows: 6-10 mm., 1.80% S; 10-15 mm., 1.65%; 15-25 mm., 1.50%; 25-35 mm., 1.35%; 35-45 mm., 1.20%. The charge should contain not more than 30% of cast Fe scrap of coarse graphitic grains, and the direct use of steel scrap should be avoided. White cast Fe may be usefully employed as it has a low Si content. Elements of unknown quantity and nature especially those tending to graphitize should not be used. A few examples of balanced charges are given. Ha (3b)

A Summary of Information on the Preparation and Properties of Pure Iron. John G. Thompson & Harold E. Cleaves. *Bureau of Standards Journal of Research,* Vol. 16, Feb. 1936, pages 105-130. A critical review of available information leads to the conclusion that really pure Fe (Fe free from significant amounts of all impurities) never has been prepared. Consequently many of the fundamental properties of Fe cannot be defined with the accuracy desirable for such an important metal. Available information on the preparation and properties of the purest available forms of Fe is summarized in the paper. WAT (3b)

American Open-Hearth Practice (Erfahrungen in amerikanischen Siemens-Martin-Werken) C. Schwarz. *Stahl und Eisen,* Vol. 56, Jan. 16, 1936, pages 68-72. A summary of the 18th Open-Hearth conference of the A.I.M.M.E., Apr. 1935. SE (3b)

Rustless Steel Castings (Les pieces moulées en aciers inoxydables) Jacques Lemoine. *Métaux,* Vol. 10, Dec. 1935, pages 305-310. Principal rustless steels used as castings are: (a) Martensitic—12-15% Cr with 0.38, 0.30 and below 0.15% C; (b) ferritic with 16-30% Cr; (c) Ni-Cr 18:8; austenitic Ni-Cr with 20-25% Cr and 10-15% Ni. All high Cr steels offer some difficulties on casting and machining. GTM (3b)

Gaseous and Solid Impurities in Ingots. J. H. Andrew. *Iron & Steel Industry,* Vol. 9, Jan. 1936, pages 149-151. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 54L/8. CEJ (3b)

Contribution to the Study of Graphite Formation and Structure in Cast Iron and its Influence upon the Properties of the Cast Metal. Heinrich Nipper. *Proceedings Institute of British Foundrymen,* Vol. 27, 1933-1934, pages 127-156. See *Metals & Alloys,* Vol. 6, Mar. 1934, page MA 94. CEJ (3b)

Open-Hearth Slags. T. Blundell. *Iron & Steel Industry,* Vol. 9, Feb. 1936, pages 174-175. Remarks are confined to acid and basic slags in the open-hearth furnace. Discussion is from the point of view of the steel melter and the works metallurgist. CEJ (3b)

Steel Castings with Special Reference to Alloy Steels. W. H. Hatfield. *Proceedings Institute of British Foundrymen,* Vol. 28, 1934-1935, pages 122-149. See *Metals & Alloys,* Vol. 6, Mar. 1935, page MA 95. CEJ (3b)

Steel Melting Slags. The Chemical Aspect. W. R. Maddocks. *Iron & Steel Industry,* Vol. 9, Mar. 1936, pages 213-214; *Blast Furnace & Steel Plant,* Vol. 24, Apr. 1936, page 347. Control of the refining process in all open hearth furnaces is effected by means of the slag. Basic electric arc furnace conditions give a slag that is absolutely reducing in character and free from Fe oxide. Acid slags can be controlled so that their oxidizing power is feeble. Basic slags are more difficult to control towards the end of the process because of the increase in oxide content. CEJ + MS (3b)

The Effect of Deoxidation on the Rate of Formation of Ferrite in Commercial Steels. D. L. McBride, C. H. Herty, Jr. & R. F. Mehl. *Transactions American Society for Metals,* Vol. 24, June 1936, pages 281-312. Rates of precipitation of ferrite from austenite at constant temperature between A_3 and A_1 for different degrees of undercool are reported for Si- and Al-killed steels, C 0.33-0.50%. Method of deoxidation has only incidental effect upon rate of formation of ferrite aside from its influence on grain-size. Fine grained austenite (Al-killed) precipitates ferrite faster than coarse grained (Si-killed). Based on equal grain-size ferrite formation proceeds at the same rates with both types of deoxidation. Log of the rate constant is a linear function of degree of undercool. Si-killed steels show greater dependence upon degree of undercool than Al-killed. At low degrees of undercool the rate of ferrite formation is faster in Al- than in Si-killed steel while with greater degree of undercool this relation is reversed. Rate of ferrite nucleation determines rate of precipitation rather than the rate of C diffusion. Ratio of ferrite formed by normalizing to that formed by annealing and difference between 2 classes of deoxidation are explained on the basis of the grain-size effects of the deoxidation methods. Rimming Steels. A. Jackson. *Iron & Steel Industry,* Vol. 9, Feb. 1936, pages 179-182. Paper read before the Newport & District Metallurgical Society on Jan. 11, 1936. An ingot of rimming steel is characterised by its thick, pure, outer skin or rim and its impure center. The rim may or may not enclose pencil shaped blow-holes. For many purposes a possible improvement would be the production of a compound ingot, having a pure rimmed skin, with a killed steel core, to which killing agent has been added when the skin has attained requisite thickness. The results of a series of experiments on the effect of various treatments on the rim are presented. CMS (3b)

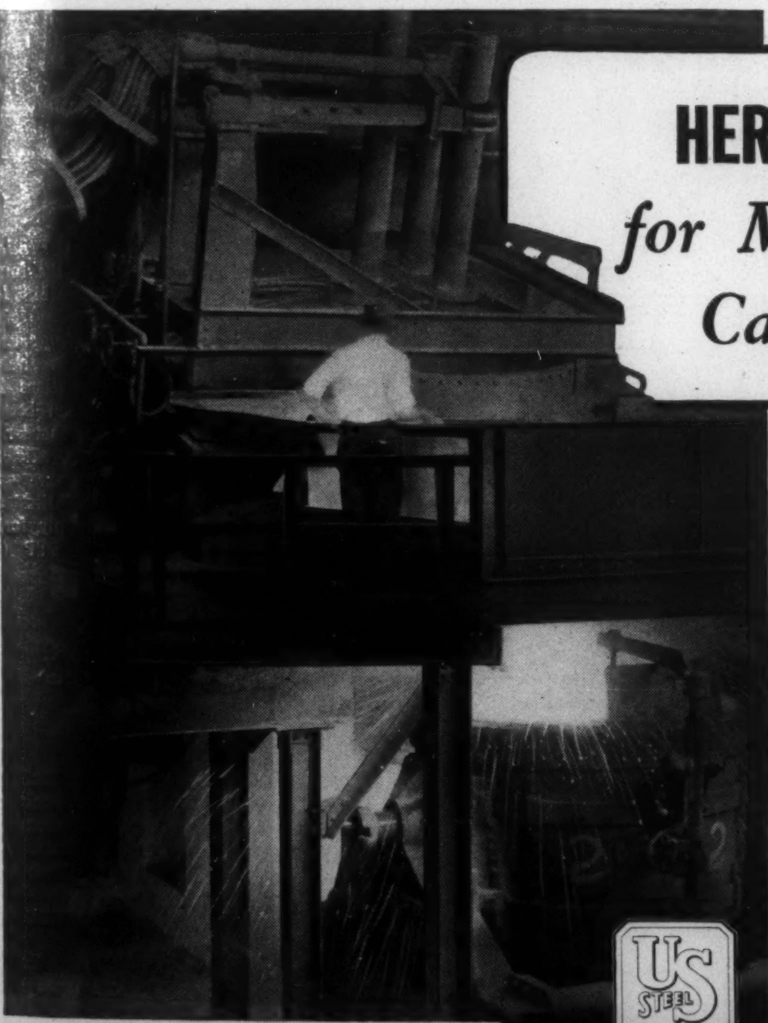
From Liquid to Solid. W. Machin. *Iron & Steel Industry,* Vol. 9, Oct. 1935, pages 6-7. A general discussion of the problems in connection with contraction which occur during the manufacture of any casting. Practical points such as core construction and backing material are considered. CMS (3b)

The Balanced Blast Cupola. W. Y. Buchanan. *Foundry Trade Journal,* Vol. 54, Jan. 16, 1936, pages 69-73. Paper read before the Scottish Branch of the Institute of British Foundrymen. The balanced-blast type of cupola is designed by Fletcher and is covered by patents, and the principles have been explained at length in numerous papers by users as well as by the British Cast Iron Research Association in their published literature. The present paper deals with the actual cases of conversion of cupolas with a view to their improvement in quality of output and economy. Several cases are considered. Following the conversion of 32″ bore cupola to the balanced blast system, the 54″ cupola was fitted with a set of tuyeres of dimensions calculated from the proportions of 32″ bore cupola. The improvement in coke consumption was again obtained under the same conditions, and a larger proportion of very heavy cast Fe scrap could be used in the furnace charges. In working this furnace the coke charge was reduced throughout the progress of the blow from 4 cwts. to 3½ cwts., and sometimes to 1 cwt. in the final charges, the Fe charges being maintained constant throughout. Comparison of types of coke, continuous running, effect of continuous spout on total C, the chill test, lime washing cupola coke, etc. are also discussed. AIK (3b)

The Electric Furnace in the Foundry (Le Four électrique en Fonderie) P. Bunet. *Usine,* Vol. 45, Apr. 30, 1936, pages 29-31. The different types and their special fields of application are reviewed. Ha (3b)



HEROULT ELECTRIC FURNACE
for Melting and Refining . . .
Capacities up to 100 Tons

THE efficiency of the Heroult Electric Furnace as a melting and refining unit for any kind of ferrous metal . . . (alloy and tool steels, iron and steel castings) . . . has won for it berths in nearly 100 mills and foundries. Either basic or acid process, any capacity from ½ ton to 100 tons; any type of charging . . . removable roof, chute, hand or machine. Call on us for regular or special designs.

Production of High Test Cast Iron (L'Élaboration des Fontes a Hautes Caractéristiques Mécaniques) Marcel Dudouet. *Bulletin de l'Association Technique de Fonderie,* Vol. 10, Feb. 1936, pages 40-48. Paper presented before the A. T. F., Mar. 7, 1936. Superheating the metal may produce either good or bad results. The addition of 95% ferrosilicon to the molten metal just before pouring produces normal graphitization without the danger of having graphite and ferrite rosettes. Oxidizing acid slags produce good structure and fluidity as well as reducing shrinkage. A cast Fe containing 2.85 to 3.00% C, 1.80% Si, 0.80% Mn, 0.09% S, and 0.25% P, may be used for castings of various sections by suitable additions of ferrosilicon or Si-Cr alloy. The effect of the P eutectic, as well as the graphite, is more dependent on form and distribution than on the quantity present. Pieces in the charge should not be under a fixed size. Electric furnace, cupola, and duplexed metals are discussed. WHS (3b)

The Production of Iron Castings. H. Field. *Journal Institution of Production Engineers,* Vol. 15, May 1936, pages 224-255. Includes discussion. A general account of the foundry methods used and the problems encountered in the production of high-grade Fe castings. JCC (3b)

Roof Temperature Control for Use in Open Hearth Furnace. M. J. Bradley. *Iron & Steel Engineer,* Vol. 13, Feb. 1936, pages 24-30. Protection afforded by roof temperature control allows maximum safe operating temperature to be used continuously. Experience on furnaces with insulated roof shows 12% increase in production and 15% increase in roof life. WLC (3b)

Steel Melting Furnaces, Automatic Control in the Open Hearth. A. J. Boynton. *Iron & Steel Engineer,* Vol. 13, Jan. 1936, pages 25-26. Automatic equipment stabilizes conditions. With such facilities intelligent operators become familiar with conditions producing the highest quality product most economically. WLC (3b)

Finishing the Heat of Steel. XLII, XLIII, XLIV. J. H. Hruska. *Blast Furnace & Steel Plant,* Vol. 24, Apr. 1936, pages 336-337, 355; May 1936, pages 422-423; June 1936, pages 514-515, 520-521. Tabulates composition, size, and melting processes used in fabrication of modern forging steels. Ingots weighing 70 tons and up are generally of inferior quality, as high segregation and large crystallization are natural consequences of heavy masses. Use of the best available raw materials and most efficient production methods will decrease the amount of these defects. Well deoxidized and degasified metal should be used. Higher Mn content seems to be beneficial. Best grades of wire are made from electric and crucible steel. Largest tonnages, however, are produced from smaller open-hearth furnaces. Quality practice is followed in producing ingots for this purpose. Suitable hot top, amounting up to 15% of ingot volume is used. Teemed ingots are cooled to below red heat to eliminate tearing or cracking in stripping.

Parts XLIII, XLIV. These instalments deal with manufacture of quality rimming steels. These are made in the basic open-hearth furnace or by duplexing in acid Bessemer and basic open-hearth furnaces. In open-hearth process, pig Fe additions are 30-38% for molten charges and 35-45% if cold. Initial Mn content should be 1.25% for heats with up to 40% pig Fe. Residual Mn content for top-poured ingots should not exceed 0.12% and for bottom-cast ingots, 0.15%. Teeming temperatures should be 50°-125° F. above m.p. of steel. Tapping temperatures above 3000° F. should be avoided. Pouring rate depends upon rimming properties of metal, determined by visual observation. Slight decrease in rate is advisable in latter stages. To prevent rise in central portion of ingot, cast Fe plates or "caps" are placed on top of ingots. This is sometimes supplemented by H_2O cooling. Addition of deoxidizers should be avoided, but, if necessary for proper rimming, Al in shot form is usually added in mold. If ingot settles 3″-4″, addition of ½ oz. Al per ton of steel will correct this. Rise of 3″-4″ can be corrected by slower pouring. To avoid introduction of Al_2O_3 in steel, some makers add 2-4 lbs. of ferro-carbon-titanium/ton in the ladle, and hold 5-8 min. MS (3b)

Steel Castings. C. K. Everitt. *Times [London] Trade & Engineering,* Vol. 38, Apr. 1936, page IX. Lists types of C and alloy cast-steels and their principal uses and outlines important features of steel foundry practice. MS (3b)

Dry Sand Cover Core Cuts Molding Cost. J. H. Eastham. *Foundry,* Vol. 64, Apr. 1936, pages 49, 110. Describes method of making dry sand cover core. Conditions under which such a method may be used are outlined. VSP (3b)

Simplifying the Complicated Mold to Cut Production Costs. J. H. Eastham. *Iron Age,* Vol. 137, Mar. 26, 1936, pages 40-42. Describes method devised for the production of a difficult casting, a tire machine table. VSP (3b)

Degree of Oxidation of Open Hearth Slags and their changes During the Process (Du degré d'oxidation des scories Martin et de leur évolution au cours de l'opération) Gabriel Husson. *Revue de Métallurgie,* Vol. 33, Apr. 1936, pages 237-242. Richarme (*Bulletin de l'Industrie minerale,* 4th series, Vol. 5, 1906, page 83) developed a formula defining the dephosphorizing properties of slags as a function of their basicity. In the present paper an attempt is made to determine the oxidizing power of slags from their content of free FeO. Ternary diagram of the FeO-SiO_2-CaO system is used as the basis for discussion. No experimental results are given. JDG (3b)

Study of Rail Steel Ingots (Contribution à l'étude du lingot d'acier pour rails) G. Grenier. *Revue de Métallurgie,* Vol. 33, May 1936, pages 318-324. Slower teeming at moderate temperatures reduces primary segregations in ingots, particularly when they are shaken even mildly as in transporting over rails while still liquid. The effect is clearly visible on cross sections of rails rolled from them. JDG (3b)

Pours Six 130-Ton Steel Castings. William G. Gude. *Foundry,* Vol. 64, May 1936, page 47. Describes the casting of 6 large castings by the Hubbard Steel Foundry, division of Continental Roll & Steel Foundry Co. Composition of metal was: C 0.22-0.27%; Mn 0.65-0.85%; Si 0.30-0.45%; S 0.045%; and P 0.03%. Total metal used was 289,000 lb. VSP (3b)

4. WORKING

The Plastic Working of Metals. Georg Sachs. *Metal Industry,* London, Vol. 48, Jan. 17, 1936, pages 51-54. Author briefly reviews the most important theoretical knowledge that has been obtained in recent years which deals with the plastic working of metal. He discusses (1) properties of material and (2) technological mechanics. Under (1) are considered (a) new methods developed for accurately determining strain hardening, (b) influence of speed for both hot and cold working and (c) effect of crystal orientation. Under (2) are included as important factors (a) properties of the material, (b) design of tools, and (c) friction. Some ingenious methods are cited which have been used in the determination of actual deformation and some processes are listed that have been improved by such studies. 5 references. HBG (4)

4a. Rolling

RICHARD RIMBACH, SECTION EDITOR

Roll Design for Shapes (Ueber das Kalibrieren von Formstahl) C. Holzweiler & T. Dahl. *Stahl und Eisen,* Vol. 56, Jan. 16, 1936, pages 57-68. Roll design for various H and I beams is discussed. SE (4a)

Tests of Hot Saws and Hot Saw Blades (Versuche an Warmsägen und Warmsägeblattern) K. Häusler. *Stahl und Eisen,* Vol. 56, Apr. 23, 1936, pages 490-492. Factors influencing hot saw cutting are discussed, such as temperature and shape of work, strength of blade, number and shape of teeth, feed, speed of cut, method of cooling, mounting of saw, and sharpening. Suggestions for improvements are made and methods of testing saw blades considered. SE (4a)

4b. Forging & Extruding

A. W. DEMMLER, SECTION EDITOR

Forging and Stamping of Stainless Steels (Forgeage et estampage des aciers inoxydables) J. Chambeyron. *Métaux,* Vol. 10, Dec. 1935, pages 291-293. Steels with 6% Cr are relatively easy to forge at 850°-1225° C. and air cooled. Steels with 13-18% Cr do not offer particular difficulties to forging at 1150°-1225° C. These steels can be readily stamped. Austenitic steels are the most difficult to forge. On solidifying, an ingot of austenitic steel forms large columnar crystals which may develop into parallel cracks on forging. These steels have a lower thermal conductivity than the ordinary steels. Before forging the ingots are heated slowly up to 850° C. then faster to 1150°-1200° C. according to type of steel. Forging temperature for 18:8 is 1200°-875° C.; for 18:8 with Mo 1200°-1000° C. Increase in Ni content lowers the initial forging temperature to 1100° and ends at 900° C. Valve steels containing 10% Cr, 3.5% Si and with or without Mo are forged at 1200°-850° C. At 1275°-1300° C. these steels are brittle and crack on forging. After forging the steel is placed in a furnace at 850° C. for a few minutes until the equilibrium temperature is established, then the steel is cooled in a pit. GTM (4b)

Manufacture of Heavy Forgings. A. B. Winder. *Times [London] Trade & Engineering,* Vol. 38, Apr. 1936, page XII. Summarizes progress in the forging and stamping industries. MS (4b)

Reducing Forging Costs with Compressed Air. C. H. Vivian. *Compressed Air Magazine,* Vol. 41, Mar. 1936, pages 4967-4972. Description is given of the general design and operation of forging hammers. Recent installations have replaced steam with compressed air for forge-shop power. Air operation becomes increasingly more economical than steam as the standby time of the hammer increases. Advantages claimed for air operation are: greater operating efficiency, greater flexibility, reduction of idling, reduction of repair and maintenance costs, decrease in amount of lubricant, and increased comfort and cleanliness. Illustrated description is included of several air compressors currently used to supply forging power. FPP (4b)

4c. Cold Working, including Shearing, Punching, Drawing & Stamping

Stamping of 18:8 Steels (Emboutissage des aciers inoxydables type 18:8) M. Lecat. *Métaux,* Vol. 10, Dec. 1935, pages 297-298. The 18:8 steels with given ductility and malleability offer no difficulty in stamping. Speed of stamping of 18:8 should be much slower than for soft C steels (about 6-8 mm./min.). After final stamping the steel should be quenched in water from 1100° C. Each treatment should be followed by cleaning in $HCl + HNO_3$ solution or $H_2SO_4 + HCl$ or in $HNO_3 + HF$ mixture. GTM (4c)

Safe Capacities for Presses and Their Relation to Shearing Strengths of Material. C. W. Hinman. *Modern Machine Shop,* Vol. 8, May 1936, pages 62-64. Tables showing the forces to be exerted in punching and shearing operations and ultimate shearing strengths for a number of metals, leathers and papers in tons for a cross section of 1 in.^{2} are given. Ha (4c)

Cold Finished Bars, Flats, Shafting, Shapes. H. W. Graham. *Metal Progress,* Vol. 29, Apr. 1936, pages 47-51. Describes cold finishing processes for steel and gives data on resultant improvement of properties. WLC (4c)

Wire Mill Drafting Tables. TOM GORE, JR. *Wire & Wire Products,* Vol. 11, May 1936, pages 221-224. The tables give the data for different percentages of partial reduction practicable for a given final reduction. Ha (4c)

The Production and Treatment of Copper Alloy Wire. *Canadian Chemistry & Metallurgy,* Vol. 20, June 1936, pages 200, 202. An historical sketch covering preparation for drawing, modern drawing machines, annealing brass wire, heat treatment of Cu alloys, pickling, and colors on Cu alloy wire. Several formulas for the latter are given. WHB (4c)

Wire-Drawing. *Times [London] Trade & Engineering,* Vol. 38, Apr. 1936, page XI. Brief discussion of drawing of wire and bars, wire-rope making, and strip rolling, with particular reference to Sheffield, England. MS (4c)

Some Practical Notes on Working and Jointing Sheet Aluminium in Motor Vehicle Construction. A. J. T. EYLES. *Aluminium & the Non-Ferrous Review,* Vol. 1, Apr. 1936, pages 324-326. Notes on the working and polishing of sheet Al for the production of automobile and motor coach panelling. JCC (4c)

The Deep Drawing of Sheet Steel, Specification and Research Problems. L. B. HUNT. *Iron & Steel Industry,* Vol. 9, Nov. 1935, pages 54-56. The temper rolling of sheets to meet the requirements of individual pressings has so far frustrated all efforts at specification by the user and has led to the development of the system whereby the supplier accepts all scrap in excess of 3 or 5% of a particular batch of pressings, and provides a contact man whose duty it is to watch the performance of his company's sheets in the press and to enable immediate adjustment of discrepancies. Sheets are far more susceptible to slight modifications in temper rolling than is disclosed by mechanical testing. To be a commercial proposition specification must first be directed towards the production cycle including rolling, pickling, normalizing and/or annealing and temper rolling. CMS (4c)

■ 4d. Machining ■

H. W. GRAHAM, SECTION EDITOR

Developments of Centerless Grinding (Les Progrès de la Rectification "Centerless"). PIERRE DEVAUX. *La Revue Industrielle,* Vol. 66, May 1936, pages 184-186. Principles of the method are discussed. Defects to be avoided are reviewed. Last section gives advantages of the method which are: speed of production, possibility of employing unskilled labor, suitability of the method for long flexible bars. FR (4d)

The Influence of Cutting Fluids on Tool Life in Turning Steel. O. W. BOSTON, W. W. GILBERT & C. E. KRAUS. *Transactions American Society Mechanical Engineers,* Vol. 58, July 1936, pages 371-378. Cutting-speed tool-life conforms to the formula $VT^n = C$, where V is the cutting speed in ft./min., T is the tool life undercut up to the time of tool breakdown in min., and n, the exponent of T, is the tangent of the angle of slope of curve plotted on double logarithmic paper; the constant C depends on shape, material, size of cut and cutting fluid. Each cutting fluid exerts a characteristic influence. In all tests, the same exponent in T is obtained when cutting dry and with aqueous solutions and emulsions, with definite constants. Addition of colloidal graphite suspended in water to an emulsion gives slightly more favorable tool life but inferior finish; when colloidal graphite of not less than 0.153% by weight is added to the emulsion the cutting speed is increased about 10% for a given tool life, and the tool life for a given cutting speed about 100%. The order of cutting fluids from lowest to highest speeds which give a tool life of 2 hrs. is:

Cutting Fluid	Speed, ft./min.
Dry cutting	83
Plain mineral oil	89
1 part oil to 16 parts water	93
Sulphurized mineral and sulphochlorinated mineral	97
1-16 emulsion containing 0.153% by wt. colloidal graphite	100
Mineral oil containing 0.153% by wt. colloidal graphite	106

Ha (4d)

Machine Tools for Machining Metals (Les Machines-Outils pour le Travail des Métaux). *La Technique Moderne,* Vol. 28, May 15, 1936, pages 347-358; July 1, 1936, pages 459-466. Describes machine tools seen in recent shows at London, Milan, Cleveland and particularly Leipzig. FR (4d)

Producing Bolts from Mild Steel Bars. *Railway Gazette,* Vol. 64, June 12, 1936, page 1125. Installation of Ward single pulley headstock capstan lathes at Crewe Works of the L. M. S. R. is briefly described. FPP (4d)

Screw Machine Practice for New Free Cutting Aluminum Alloys. J. F. CONEEN. *Iron Age,* Vol. 137, Mar. 5, 1936, pages 33-35. From a paper read before the eastern division of the Screw Machine Products Association at New York. Al and its alloys differ in their machining properties, and therefore changes in machining and tool practice are necessary. A new screw machine alloy known as 11S has been developed especially for fabrication of parts on automatic screw machine, and machinability comparable to brass. Gives details of machining 11S alloys and describes various tools used. Includes a table giving speeds and feeds used in machining 11S Al screw machine stock. VSP (4d)

Stresses due to Machining (Ueber Bearbeitungsspannungen). W. RUTTMANN. *Technische Mitteilungen Krupp,* Vol. 4, June 1936, pages 89-97. Present knowledge of stresses originated in materials by machining operations is reviewed. Samples of equal heat treatment can show both tensile and compressive stresses according to the kind of mechanical treatment to which it was subjected. In general, when slowly machined with good cooling, compressive stresses are originated in the marginal zone while when machining quickly and without cooling, and in grinding, tensile stresses show up. The results are critically discussed and practical applications in the mechanical treatment of metals and their correct shaping are attempted. 42 references. Ha (4d)

5. HEAT TREATMENT

O. E. HARDER, SECTION EDITOR

Treatment of Steel for Clock and Gramophone Mainsprings. F. L. TINGLE. *Iron & Steel Industry,* Vol. 9, Dec. 1935, pages 121-124. The material used may be either straight C steel, Si-Mn, or Cr-V, produced either in the open-hearth or electric furnaces; the precise material which is used being determined by the requirements which have to be met and the price the customer is prepared to pay for the product. Attention is restricted to plain C steels; typical composition 1.05% C; 0.42% Mn; 0.25% Si; 0.02% P; 0.015% S. Billets from which the strip is produced are hot rolled to strip finishing at about 14 to 16 gage thickness. Further reduction in thickness then takes place by cold rolling, with intermediate annealings. For correct hardening quenching is done from 760° to 780° C. at the Ac point. CMS (5)

Axle Shafts Are Given Unusual Heat Treatment. A. H. ALLEN. *Steel,* Vol. 98, Apr. 6, 1936, pages 32-35. Describes practice of the White Motor Co., Cleveland, O. Steel for rear axle shafts contains 0.55-0.85% Cr, 1.60-2.10% Ni, 0.15-0.25% Mo, and 0.40-0.50% C, with preference on the upper end of this range. Shaft is machined before heat treatment. Hardness before heat treatment is 220-250 Brinell. Scale preventing coating of kaolin and Na_2SiO_3 is applied to splines. Shafts are heated in an oil-fired furnace, with a slightly reducing to neutral atmosphere, to 1500° F., and held at that temperature for 15-20 min. Charge and furnace are brought down to 1270° F., for smallest size shaft, in 2½-3 hr., and shafts are transferred as speedily as possible to an oil quenching bath at 140°-160° F. and left there for 2-2½ min. They are placed immediately in an oil-fired bath of $NaNO_3$ at 900°-1000° F. and are drawn there for 2 hrs. They are then quenched in hot H_2O. Brinell hardness after heat treatment is 368-388. To facilitate drilling bolt holes in flange, outer rim is drawn back by rolling flange several times in a Pb bath heated to 1400° F. Shafts have a minimum elastic limit of 160,000 lbs./in.², ultimate strength of 180,000 lbs./in.², elongation of 15% in 2 in., and reduction of area of 50%. MS (5)

Heat Treatment of Driving Gear Parts. I. E. LOBANOV. *Liteinoe Delo,* Vol. 7, No. 4, 1936, pages 5-11. In Russian. Inferior physical properties of parts in question led to investigation of their heat treatment. The cause of troubles was connected with alumina stringers. (5)

■ 5a. Annealing ■

Physical Changes in Hardening and Annealing of Steel (Tillstandändringen vid härdning och anlöpning av stal) GUNNAR HÄGG & EINAR OEHMAN. *Jernkontorets Annaler,* Vol. 120, Apr. 1936, pages 143-166. Discussion of von Vegesack's results (*Jernkontorets Annaler,* Vol. 120, Feb. 1936, page 49) and reply. HCD (5a)

Heat Treating Steel Wire Rods in Coils for Bolt Stock. J. H. BROWN. *Industrial Gas,* Vol. 14, June 1936, pages 13, 16-17. A gas-fired bell-type furnace is used for annealing; operating data are given. Ha (5a)

Annealing for Quality. LEE WILSON. *Industrial Heating,* Vol. 3, Aug. 1936, pages 523-525. Vertically arranged Cr-Ni tubes through which the fuel passes to the bottom end where it is burned, are claimed to give a more uniform and economical annealing process. Ha (5a)

Study of Soaking Time Used in Thermal Treatment of Aluminum Alloys. I. I. TUTOV. *Metallurg,* Vol. 11, June 1936, pages 83-90. In Russian. Al alloys containing 4.12% Cu, 1.53 Mg, 1.68 Ni and duralumin were investigated. The only result of a long soaking time is grain growth in metals. The usual soaking time, 2.5-4 hours should be reduced to 25-30 minutes. (5a)

Annealing Steel in Controlled Atmosphere. I. T. BARUZDIN. *Metallurg,* Vol. 11, June 1936, pages 66-76. In Russian. Steels with different C content were annealed in dissociated NH_3. The surface of metal was usually slightly oxidized producing grayish coloration. Under 650° C. no decarburization was observed during 3 hours, maximum time of treatment. With higher temperatures decarburization increased in proportion to C content. (5a)

■ 5b. Hardening, Quenching & Drawing ■

Automobile Frame Steel and its Heat Treatment. G. N. FOMIN & S. A. BERNER. *Kachestvennaia Stal,* Vol. 4, No. 1, 1936, pages 39-43. In Russian. Steel used has the composition: 0.24-0.34% C, 1.25-1.50 Mn, 0.25 Si. Some troubles with inferior physical properties led to investigation of the temperatures involved, so that instead of using one quenching temperature for all steels they were subdivided in classes varying about 0.02% in C and about 0.05% in Mn for which intermediate temperatures were used. Many data are given. (5b)

Silicomanganese Spring Steel and Its Heat Treatment. G. N. FOMIN & S. A. BERNER. *Kachestvennaia Stal,* Vol. 4, No. 1, 1936, pages 34-39. In Russian. Investigation was conducted to determine the influence of variation in composition from a standard on physical properties of the metal. Standard analysis was: 0.50-0.60% C, 0.45-0.80 Mn, 0.35 S, 0.45 P, 1.3-1.8 Si. Complete data on physical testing are furnished. All physical requirements are met when C content is higher than 0.60%; under 0.50% the results are unsatisfactory. With Si at the lower limit of 1.30% and Mn below it, 0.35%, steel is on the margin of desired physical qualities. When Si was increased above its upper limit, 2.05%, up to 2.2% physical properties were fully met, but the material was a bit hard in the as furnished state which interfered with its cutting. 900-920° C. can be recommended as quenching temperature in production. (5b)

Application of Electric Furnace to the Heat Treatment of Springs (L'Application du Four Electrique au Traitement Thermique des Ressorts) JEAN GODDOT. *Science et Industrie (Electricité),* Vol. 20, Feb. 1936, pages 48-50. As indicated by endurance studies of steels, external layers of springs must be correctly treated and not impaired by the treatment. Furnaces using other fuels are not so easy to control as electric furnaces. The latter show following advantages: regularity, control of atmosphere, automatic control of temperature and ease to distribute heat as needed in different parts of the furnace, ease of insulation, good thermal efficiency. The use of electric furnaces does not solve the problems encountered in spring treating if they are not correctly controlled. FR (5b)

Shorter Hardening Process. *Engineer,* Vol. 61, Apr. 24, 1936, pages 447-448. Discusses results obtained on the "Shorterizing" of C and alloy steels for the purpose of hardening them. The depth affected by the Shorter treatment was 0.11" to 0.13", and of this 60 to 89%, depending on class of steel, was martensitic. Best results from "Shorterizing" are obtained from use of forged or cast steel; there is nevertheless a wide field of application with pearlitic cast Fe. A new development for the Shorter process is the Shorter-double-duro process designed for hardening pins and journals of crankshafts and similar cylindrical parts where wear is excessive. Tabulates results of tests. VSP (5b)

■ 5e. Carburizing ■

Modern Gears. E. F. DAVIS. *Steel,* Vol. 98, Apr. 27, 1936, page 67. Abstract of paper before tri-chapter meeting of the Cincinnati, Columbus, and Dayton chapters, American Society for Metals, Apr. 21, 1936. Deals principally with forged steel gears for automobile transmissions. Rack-type cutting is favored. Gears are cut to close limits, hardened, then teeth are lapped to finished dimensions. Cyanide process is used for hardening to preserve surface finish and to produce hard surfaces to prevent wear. Cyaniding does not produce noisy gears; distortion is not caused by rapid heating; carburized gears are not noisier than oil-hardened gears; and gears are not noisy because they distort in fire. Distortion can be traced to quenching and not heating. Accurate cutting is necessary for quietness. Close control of cutting and heat treating is required for best results. Pitting of gear teeth causes early failure. Inclusions in steel cause trouble in cutting, increase cutter expense, and are a source of failure. Overstressing of metal during cold shearing may result in cracking of gears. Overburnishing causes surface to separate and pit, leading to fatigue failure. States in discussion that cyanide method can be used advantageously for all gears if they are not too large and C content is not over 0.45%. Maximum hardness which can be cut on rack-type cutter is 228 Brinell. MS (5e)

Determination of the Depth of Cementation and Speed of Carbon Diffusion in Steel. S. S. KANFOR. *Metallurg,* Vol. 11, June 1936, pages 55-65. In Russian. Parabolic formula $x^2 = Kt$ expressing diffusion during cementation is based on the assumption of a straight line relation between the amount of C absorbed and the difference in concentration. It is derived with a further assumption that the relation between the depth of penetration and amount of C absorbed is also a straight line function. The latter seems to be valid for thin coating, but for heavier carburized layers difference in concentration is not related to the depth of case. This was checked by literature data available and some experiments by the author. Speed of penetration in specimens isolated from outside influences was determined by carburizing steel bars for 40, 80 and 100 hours at 950° C., checking the depth of case on extra samples and heating the specimens for additional 100 hours. Before subjecting them to the latter operation they were thoroughly cleaned from carbonaceous deposits on their surface and coated with a gas tight compound. The increase in depth was the same indicating the constancy of C diffusion at a given temperature and independence of the difference in concentration, which was continuously decreasing. Linear speed of C migration in steel during cementation is expressed by the equation $v = v_k + v_x$ where v_k is the speed of C migration depending only on temperature and type of steel, provided steel is isolated from any outside influences. v_x is specified by the action of cementing medium becoming therefore a function of the distance from it. After a proper mathematical treatment of this expression the total depth of cementation can be expressed as $x = \frac{t}{k} + \sqrt[n+1]{\frac{t}{c}}$ where coefficients n, k and c can be determined experimentally. Application of this formula to published data showed its correctness. (5e)

■ 5f. Nitriding ■

Selective Nitriding. FEDERICO GIOLITTI. *Metal Progress,* Vol. 30, July 1936, pages 62-63. Articles to be treated are varnished where they are to be nitrided and then coated with Sn electrolytically. The varnish is then removed and parts subjected to nitriding. WLC (5f)

Chapmanizing. An Improved Case Hardening Process. *American Gas Journal,* Vol. 144, May 1936, pages 23-24. Steel is heated in the presence of an active N gas. A liquid bath is used for heating and also to carry the active N direct to the steel under treatment. N is furnished from NH_3" gas in cylinders; the active N is formed by an electrical reaction of the NH_3" in the "chapmanizer." Physical characteristics and properties of the treated steels are given. CBJ (5f)

6. FURNACES, REFRACTORIES AND FUELS

M. H. MAWHINNEY, SECTION EDITOR

The Balanced Blast Cupola. L. W. Bolton. *Iron Age,* Vol. 137, May 21, 1936, pages 38-40, 93. Describes a new design furnace developed by J. E. Fletcher, known as a balanced blast cupola (British patent, 333,322 and United States patent, 1,853,120). 4 rows of tuyeres are used which deliver air from wind belt. In converting existing cupola to the new design, a new wind belt, large enough to accommodate the 3 rows of auxiliary tuyeres is usually required. Melting rate of these cupolas is between 12 and 15 tons/hr. Fuel consumption in new furnace is considerably lower than in a normally designed cupola. Highly superheated metal may be produced in the cupola. VSP (6)

Kinetics of Some Reactions of Interest to Ceramists—The Disintegration of Blast Furnace Linings Due to Carbon Deposition. C. C. Furnas. *Journal American Ceramic Society,* Vol. 19, June 1936, pages 177-186. Deposition of C from dissociation of CO is responsible for formation of large transverse cracks followed by crumbling and complete disintegration of the refractory. Experimental work is reported for several types of brick at various temperatures around 450° C. exposed to various % CO atmospheres. Fe_2O_3 is shown to induce the disintegration by favoring deposition of C while Fe_3O_4 does not aid in decomposition of CO. It is shown by results that the brick which are more completely fired to give desirable properties contain Fe as Fe_2O_3, which aids disintegration of the more completely fired brick. WB (6)

Equipment for Hardening Gears without Oxidation. J. B. Nealey. *Metal Progress,* Vol. 29, June 1936, pages 45-48. Describes furnace and quenching equipment and layout. WLC (6)

Kelsey-Hayes Melts Iron and Steel in Brackelsberg Units. Frank J. Oliver. *Iron Age,* Vol. 137, Apr. 9, 1936, pages 46-48. **Detroit Foundry Melts Metal in Rotary Furnaces.** Pat Dwyer. *Foundry,* Vol. 64, Apr. 1936, pages 46-48, 85, 89. Describes the furnace which is one of the largest installations in this country. The unit, in conjunction with an electric furnace, is used for melting gray Fe and alloy steel for brake drums and flanges, and composite drums and flanges by the Kelsey-Hayes Wheel Co. VSP (6)

Natural Gas for Cutting, Galvanizing and Soldering. F. Pexton. *Industrial Gas,* Vol. 14. June 1936, pages 9-10. Some instances are described in which savings were effected in manufacturing processes by substituting natural gas for acetylene in cutting, coke in galvanizing, and hydrogen in soldering. Ha (6)

Refractories. W. J. Rees. *Times [London] Trade & Engineering,* Vol. 38, Apr. 1936, page XXVII. Discusses modern developments. MS (6)

Modern Furnace Applications of Refractories and Insulation. J. L. Spence & J. W. Craig. *Iron & Steel of Canada,* Vol. 19, Feb. 1936, pages 3-9; Apr. 1936, pages 5-7; June 1936, pages 12-16. Refractories available and their general characteristics, fireclay brick, cements, monolithic materials, insulations, and definitions of terms are reviewed and applications in industrial furnaces described. A table is given showing basic, acid and neutral refractories, and high and low temperature insulation with their particular fields of application. Ha (6)

Technical Advances and Evolution of Uses of Electric Radiation Furnaces (Progrès techniques et évolution des applications des fours électriques à rayonnement) R. Sevin. *Journal du Four Electrique,* Vol. 45, Apr. 1936, pages 132-137. The latest developments in the furnace previously described (*Journal du Four Electrique,* July 1934), consist in eliminating eddy currents and induction by placing both positive and negative leads at one end of the furnace and leading the current through the electrode by means of a Cu screen placed inside of the furnace housing. Lining of a mixture of zirconite and alumina ("zirconal") is used permitting work at 1650° C. Furnaces work rapidly, and are built up to one ton capacity. Melting pure Fe, Ni and 71% Fe-Cr for 18-8 stainless steel resulted in C content of less than 0.05%. 17 furnaces are already in operation and 8 in the process of construction. JDG (6)

Electrical Annealing and Hardening Furnaces of the Light Metal Industry (Elektrische Glüh- und Vergüteöfen der Leichtmetall-Industrie) U. Schwedler. *Elektrowärme,* Vol. 6, June 1936, pages 171-177. Shaft, trough and continuous furnaces with and without air circulation (convection heating) are described and operating data given. Ha (6)

Modern Refractories in the Steel Industry. L. J. Trostel. *Iron & Steel Engineer,* Vol. 13, Apr. 1936, page 7. Abstract of paper presented and discussed at A. I. & S. E. E. Engineering Conference, Youngstown, Apr. 1936. Analysis of the refractory requirements of the steel industry. WLC (6)

Experiment on a Furnace Roof Arch. C. Wolstencroft. *Heat Treating & Forging,* Vol. 22, May 1936, pages 254, 257. Much difficulty in a large annealing furnace was caused by longitudinal expansion of brick roof rubbing the door when it was raised and lowered. Front part of roof arch and door lining required continuous maintenance. Furnace operated at 1200°-2000° F. The front section of this roof arch was replaced by a precast refractory concrete arch, which was hoisted into position 24 hrs. after pouring. Arch is 13½′ between piers; inner radius is 10¼′ outer radius, 12′ 5″; width, 18″; and overall length, 15′ 8″. It has been in service 1 year. Several cracks have developed which appear to affect neither furnace operation nor arch life. Had fire-brick been used, this part of the roof arch would have been replaced twice in this time. MS (6)

Modern Annealing and Hardening Furnaces for Quantity Production (Neuzeitliche Glüh- und Härte-Oefen für Massenteile) C. Hummel. *Feinmechanik & Präzision,* Vol. 44, June 1936, page 100. Descriptive. Ha (6)

Small Atmospheric Furnaces for High Melting Temperatures. E. L. Harris. *Industrial Gas,* Vol. 15, July 1936, pages 9-10. Temperatures up to 2000° F. can be obtained in small furnaces for carburizing and dental work. Ha (6)

Heat Treatment of Metals. W. Y. Anderson. *Electrical Review,* Vol. 118, June 12, 1936, pages 873-874. Efficiency, cleanliness, and ease of control of electric furnaces and improved quality of work turned out are leading to their increasing use for annealing, hardening, carburizing, tempering, etc. Gives examples of costs, and describes briefly 2 installations. MS (6)

Superheats and Refines Gray Cast Iron. Edwin Bremer. *Foundry,* Vol. 64, Jan. 1936, pages 26-27, 67. Describes a new auxiliary melting unit, an adjunct to the cupola, developed by the Miller Foundry Co., Columbus. The unit is gas fired and of simple construction. VSP (6)

Tempering Furnace with Mechanical-Controlled Convection Currents. *Engineering,* Vol. 142, Aug. 7, 1936, pages 158-159. Describes a gas-heated furnace developed by Despatch Oven Co., Minneapolis. Its operation is based on mechanical convection. A motor driven rotary fan in upper part of furnace drives heat down into heating chamber, from which it passes out for recirculation after giving up heat. Consists essentially of double-walled insulated sheet steel combustion chamber in base of which are the gas burners. Two types are available, one for temperatures from 300°-800° F., and other for temperatures from 300°-1,200° F. VSP (6)

Slab Heating Furnaces at Bethlehem's New Continuous Strip and Sheet Mill. *Industrial Heating,* Vol. 3, July 1936, pages 435-438. The furnaces heat 165 tons of slabs/hr., the slabs being 5 to 16 ft. long and 18 to 50 in. wide; they are heated by a mixture of blast furnace and coke oven gas of 285 B.t.u./ft.^{3} Heat is recuperated by preheating the combustion air to 700°-800° F. Combustion control is described. Ha (6)

Ford Installs the Largest Continuous Electric Furnace in the World. *Industrial Heating,* Vol. 3, Aug. 1936, page 500. Brief description of a bright-normalizing, roller hearth furnace for 7½ tons/hr. of 2335 kw. rating in 3 chambers; total length 325 ft. Ha (6)

Coke Oven Repairs. *Iron & Coal Trades Review,* Vol. 133, July 10, 1936, page 57. Cracks in furnaces were repaired successfully by spraying cement directly onto the hot brickwork. Procedure, mixture of cement, and equipment are described. Ha (6)

The Slag Resistance of Steel Works Refractories. J. H. Chesters. *Iron & Steel Industry,* Vol. 9, Jan. 1936, pages 147-148. The general cause of failure is slag attack. A precise study of the action of slag on steel works refractories would require a great deal of knowledge about equilibrium conditions and reaction rates, which is not likely to be available in the near future. It is possible to carry out comparisons of the slag resistance of various refractories by means of cone and pill tests and by simulating large-scale conditions in a small induction furnace. Physical tests, such as modulus-of-rupture at high temperatures and permeability, enable some idea to be gained of the probable influence of physical factors. CEJ (6)

The Action of Water Vapor on Silica Bricks at High Temperatures, and its Possible Industrial Significance. A. E. Dodd. *Transactions Ceramic Society,* Vol. 35, May 1936, pages 223-243. 9 representative silica brick samples, cut from open hearth furnace bricks, were tested to disruption by exposure to the action of steam, at a temperature of 1500°-1600° C. The bricks failed by plastic flow or local rotting. Microsections of the original samples, and of the test bricks, were examined. It is concluded that a high ferric oxide content causes failure; that a low lime content also appears to accelerate failure; that some volatilization of silica would account satisfactorily for the rotting effects, and that water vapor causes a marked decreaase in the viscosity of the bond. The author discusses the industrial significance of the results obtained. GTM (6)

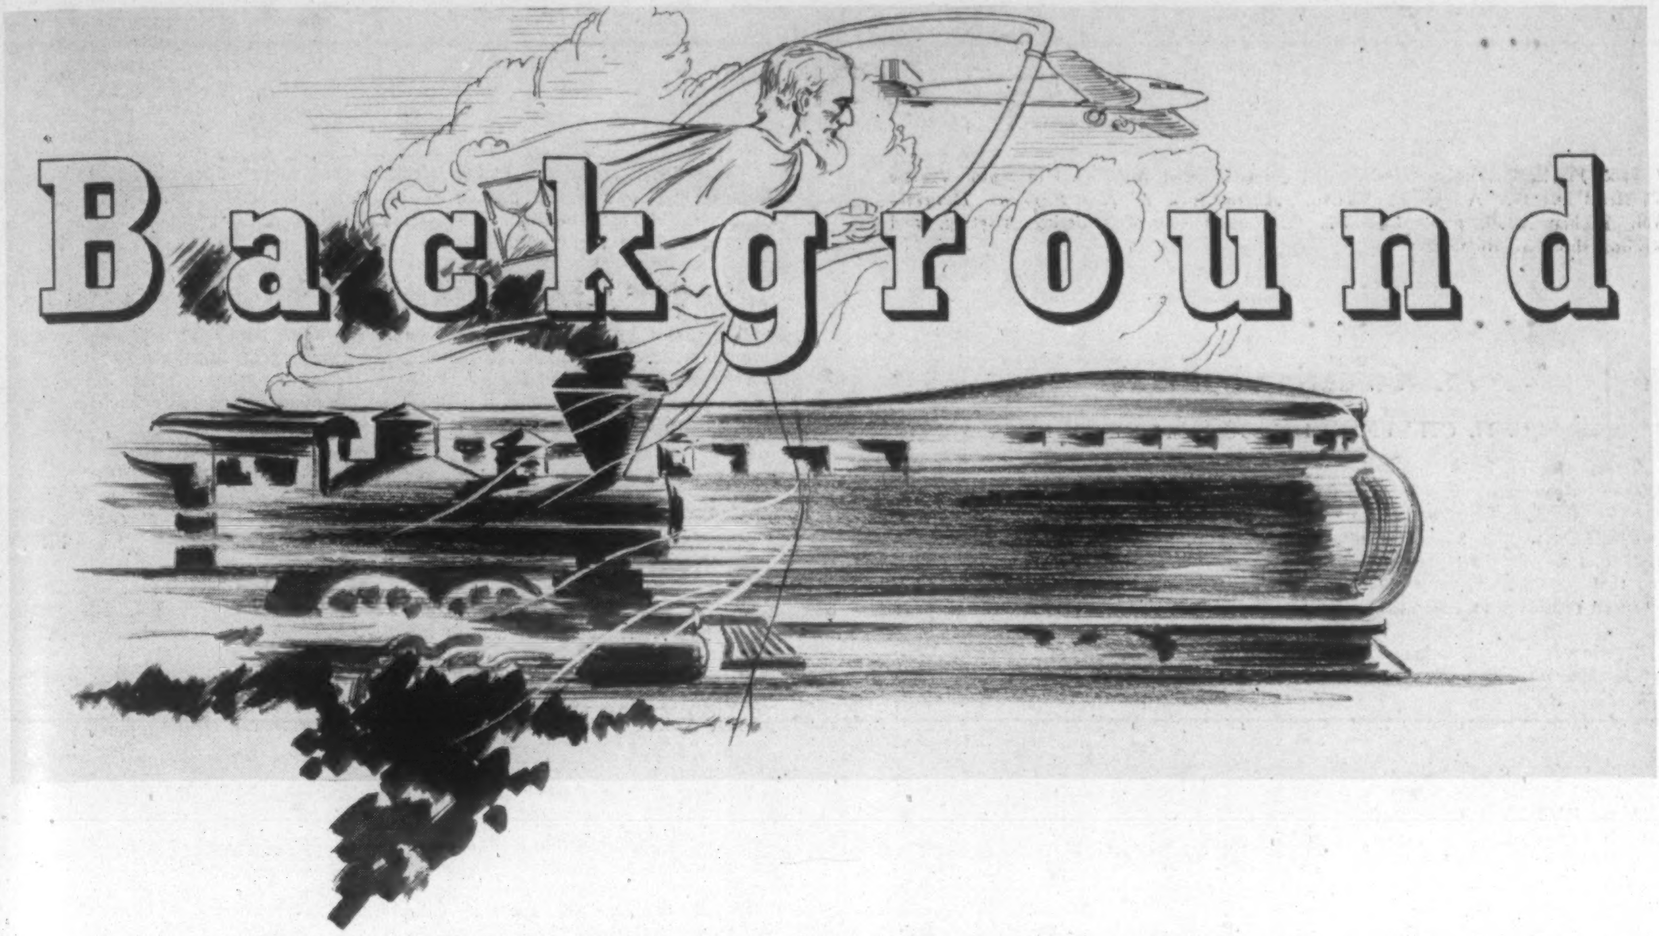
Coke Research. W. Davidson. *Journal West of Scotland Iron & Steel Institute,* Vol. 43, Mar. 1936, pages 117-128. By blending proper materials with the coal before carbonization, the quality of metallurgical coke is improved and satisfactory coke can be made from coals not otherwise suitable. Poor coke may be caused by: (1) a large percentage of volatile matter at the end of the plastic temperature range (450°-550° C.) which results in a weak highly fissured coke; (2) a deficiency of plastic material to bind the coal particles sufficiently to give a non-abradable coke. Coals of high volatile content are blended with finely ground high temperature coke or anthracite. Weakly caking coals are blended with bitumen or pitch. The screening and shatter indices, bulk density, ash content, and chromic acid oxidation value are given for a large number of cokes made from various blends. FGN (6)

The "Deblanchal," a New Rotary Melting Furnace. C. F. Herington. *Iron Age,* Vol. 137, June 11, 1936, pages 50-53, 114. See *Metals & Alloys,* Vol. 7, June 1936, page MA 297R/3. VSP (6)

Recent Developments in Refractories. C. E. Moore. *Metal Industry,* London, Vol. 48, Jan. 3, 1936, pages 8-13; discussion, Jan. 10, 1936, pages 36-37. See *Metals & Alloys,* Vol. 7, July 1936, page MA 348R/4. HBG (6)

The Chill-proofing of Refractory Masses (Beitrag zur Abschreckprüfungfeuerfester Massen) A. Möser. *Feuerungstechnik,* Vol. 24, Jan. 1936, pages 9-10. Methods of simultaneously developing resistance to thermal shock and to corrosion in refractory materials are discussed. FPP (6)

Bituminous Coal for Higher Temperatures in Open-hearth Furnaces. Theodore Nagel. *Blast Furnace & Steel Plant,* Vol. 24, May 1936, page 427; June 1936, pages 523, 542. See *Metals & Alloys,* Vol. 7, July 1936, page MA 348R/6. MS (6)



Yesterday's goal is our starting point today—that has been the background of The Chas. Taylor Sons Company's industrial progress since 1864, when it was born with the idea of producing better firebrick and super refractories.

And this dominant idea is now—and will continue to be—the motive power of our organization.

Breasting the current of opinion, censure, trial and error, knowing that every great battler of men or industry has been confronted with the desire to turn back or follow the line of least resistance, we have overcome tradition and precedence, buoyed up by the fact that perfection is always ahead.

Our parallel ambition is: never to place upon the market any product until it has proven in the laboratory and in actual service to be a real contribution to industry.

We glance at the background "lest we forget"—then forge ahead to greater achievements inspired by our attainments—our claims verified, and our leadership justified by an abundance of testimonials.

Whether it be firebrick or P. B. Sillimanite super refractories, carrying the Chas. Taylor trade-mark, available to the glass and metal industries in feeder parts, special shapes and plastics, we are qualified to serve you satisfactorily.

TAYLOR
P B
SILLIMANITE

All P. B. Sillimanite made by The Chas. Taylor Sons Company bears this trade-mark—your guarantee of satisfaction.

THE CHAS. TAYLOR SONS CO.
CINCINNATI, OHIO

Some Practical Notes on Working and Jointing Sheet Aluminium in Motor Vehicle Construction. II. A. J. T. EYLES. *Aluminium & Non-Ferrous Review,* Vol. 1, May 1936, pages 385-387. The operations of soldering, riveting, and welding sheet Al are discussed. JCC (7)

■ 7a. Soldering & Brazing ■

C. H. CHATFIELD, SECTION EDITOR

Saving of Tin in Soft-soldering (Einsparung von Zinn beim Weichlöten) E. LÜDER. *Feinmechanik & Präzision,* Vol. 44, Mar. 1936, pages 41-42. Sn is, from the German standpoint, a metal to be economized. Soft solders can be made satisfactorily with a Sn solder of 12-15% Sn to which Cd and Bi are added. Tests over 2 years have shown, however, that these solders do not flow very easily, and that certain molecular ratios between Sn and Cd must exist to obtain sufficient corrosion resistance of the soldered joint. Ha (7a)

Experiments with Reaction Solders for Aluminum (Versuche mit Reaktionsloten für Aluminium) NEUBAUER-NICOLINI. *Aluminium,* Vol. 18, Apr. 1936, pages 139-142. The chemical process of a reaction solder with Al, i.e. a salt mixture, out of which a metal constituent, mostly Zn, is deposited in contact with Al upon heating, was investigated. The salt melt etches the Al and thus removes the harmful oxide film. The Al chloride formed in the reaction evaporates together with a part of the volatile compounds of the salt mixture. The strength of soldered joints is better for Zn rich salt mixtures than with Sn rich mixtures. A few reaction solders and their characteristics are given in the table.

$ZnCl_2$%	$SnCl_2$%	NH_4Br%	NH_4Cl%	NaF%	Metal deposition on Al takes place at °C.

■ 7b. Welding & Cutting ■

E. V. DAVID, SECTION EDITOR

Flame Cutting of Steel for Welding. *Journal of Commerce, Shipbuilding & Engineering Edition,* July 9, 1936, page 1. A series of experimental tests carried out on V-butt welded specimens having chamfered joints prepared by using the oxy-acetylene cutting flame, and on electrically welded fillets to close square tee joints having the fraying edge of the T member cut by the oxy-acetylene flame, by means of a number of severe alternating impact tests have demonstrated that the flame-cutting preparation has no deleterious effect on the strength of the joint. JWD (7b)

Gas Welding Aluminum and Its Alloys. G. O. HOGLUND. *Metal Industry,* London, Vol. 48, Jan. 3, 1936, pages 5-7. See *Metals & Alloys,* Vol. 7, July 1936, page MA 354R/3. HBG (7b)

Technical Rules for Fusion Welding. General Specifications (Règles Techniques de Soudure Autogène. Specifications Générales). *Revue de la Soudure Autogène,* Vol. 28, Apr. 1936, pages 2-3. Tentative French general specifications established by the "Comité de Normalisation de la Soudure." Following points are covered in these preliminary specifications: (1) Aim and application, (2) guaranty, responsibility of manufacturers, (3) preparation and execution of welds, (4) classification of work, special specifications for particular jobs. FR (7b)

Repair of a Shearing Machine by Bronze Welding (Reparation d'une Cisaille par Soudo-Brasure) *Revue de la Soudure Autogène,* Vol. 28, Apr. 1936, page 16. Typical example of repair of large broken shearing machine frame is described and illustrated. FR (7b)

Bad Welders (Les Mauvais Soudeurs) *Revue de la Soudure Autogène,* Vol. 28, May 1936, pages 2-3. Illustrates good and bad welded joints. It is concluded that welders should follow well established practical rules for welding. FR (7b)

Some Difficulties Encountered in the Practice of Spot Welding (A Propos de Quelques Difficultés dans la Pratique de la Soudure par Points). R. DE LONGCHAMP. *Bulletin de la Société des Ingénieurs-Soudeurs,* Vol. 7, Mar.-Apr. 1936, pages 2123-2130. Lecture before the French Welders' Society. Spot welding machines have to be designed in order to be operated by unskilled labor. Furthermore it is necessary that resistance be constant although constant pressure is of no significance. In spite of the difficulties reviewed, author thinks that spot welding is, economically speaking, without competitor. F R(7b)

Welding on Gas Cut Edges (La Soudure sur Bords Oxy-Coupés) *Revue de la Soudure Autogène,* Vol. 28, May 1936, page 12. This type of welding is quite possible when edges have been very rapidly cleaned with file or chisel. It is not true that the presence of oxide film on the edge prevents the making of correct welded joints. Oxide inclusions are due to unskilled welders and not from state of welded edges. FR (7b)

Conventional Marks for Fusion Welding (Les Signes Conventionnels en Soudure Autogène) *Revue de la Soudure Autogène,* Vol. 28, Mar. 1936, pages 7-9. Discusses difference between international tentative marks adopted at the Würzburg meeting and the French proposals. FR (7b)

Oxy-acetylene in Shipyards. *Shipbuilding & Shipping Record,* Vol. 37, June 11, 1936, pages 774-776; June 18, 1936, pages 809-812. Abstract of a report prepared by the British Acetylene Association. Deals with the application of the oxy-acetylene flame in the building and repairing of ships and the use of oxy-acetylene welding and cutting as applied in marine engineering for the repair of such parts as shafting, propellers and Diesel engine pistons, and for demolition purposes and shipbreaking. JWD (7b)

Oxy-Acetylene Torches (Les Chalumeaux Oxy-Acétyléniques) *Soudure et Oxy-Coupage (Supplement to La Revue de la Soudure Autogène)* Vol. 13, Apr.-May 1936, page 293. Notes on torches with the following trade marks: "Varial", "Primox", "Super Charledave" and "Sauvageau". FR (7b)

Welding of Aluminum (La Soudure de l'Aluminium) *Soudure et Oxy-Coupage (Supplement to La Revue de la Soudure Autogène),* Vol. 13, Apr.-May 1936, page 294. Problems met in the welding of Al are discussed. FR (7b)

Bronze Welding of Cast Iron Castings (La Soudo-Brasure des Pièces en Fonte) *Soudure et Oxy-Coupage (Supplement to La Revue de la Soudure Autogène),* Vol. 13, Apr.-May 1936, page 290. Practical repairs are illustrated. FR (7b)

Welding of Zinc Coated Sheets (L'Assemblage des Tôles Galvanisées) *Soudure et Oxy-Coupage (Supplement to La Revue de la Soudure Autogène),* Vol. 13, Apr.-May 1936, page 291. Practical description of the 2 methods available. FR (7b)

Welded Bridges and Overhead Structures (Constructions Métalliques Soudées) *Soudure et Oxy-Coupage (Supplement to La Revue de la Soudure Autogène),* Vol. 13, Jan.-Mar. 1936, page 285. Typical examples are illustrated. FR (7b)

Applications of Cutting Torch (Les Applications du Chalumeau Coupeur) *Soudure et Oxy-Coupage (Supplement to La Revue de la Soudure Autogène),* Vol. 13, Jan.-Mar. 1936, page 286. Typical practical applications are given. FR (7b)

Welding of Copper (La Soudure du Cuivre) *Soudure et Oxy-Coupage (Supplement to La Revue de la Soudure Autogène),* Vol. 13, Jan.-Mar. 1936, page 283. Principles for welding of thin, medium and thick Cu sheets and plates. FR (7b)

Automatic Oxy-Acetylene Welding (La Soudure Oxy-Acetylenique Automatique) *Soudure et Oxy-Coupage (Supplement to La Revue de la Soudure Autogène),* Vol. 13, Jan.-Mar. 1936, page 284. Describes briefly "Sa Frap" welding machines. FR (7b)

Welding of Piping (La Soudure des Canalisations) *Soudure et Oxy-Coupage (Supplement to La Revue de la Soudure Autogène),* Vol. 13, Jan.-Mar. 1936, page 282. Practical article giving chief principles to be observed. FR (7b)

Resistance Flash Welder Increases Production of Broad Strip Mill. *Steel,* Vol. 98, May 11, 1936, page 56. Welder joins strip into a continuous piece that can be pickled and processed without interruption. Strip to be pickled is unreeled and passed into a looping pit which holds enough stock to allow 1 min. for welding ends together. Rear end of coil is squared off in an upcut shear and front end of another coil is trimmed off similarly and fed into welder. Ends are lined up by gages, and, at touch of a control button, are clamped in place while current goes on and off. After completion of weld, strip moves along until joint is in position in a trimmer, where burr is removed by a pull shear before strip passes into looping pit. MS (7b)

Tests with Coated Filler Metal Bars (Note sur Quelques Essais de Métaux d'Apport Enrobés) JEAN BRILLIÉ. *Bulletin de la Société des Ingénieurs Soudeurs,* Vol. 7, Jan.-Feb. 1936, pages 2030-2033. Lecture before the French Welders' Society. Conclusions of the author are: Coating improves quality of welds obtained but chief advantage of coating rods is the ease of welding for the operator who can speed up his production. It also reduces amount of flux used for welding non-ferrous metals. FR (7b)

Flame-cutting in Artcraft (Brenschneiden im Kunsthandwerk) J. BLÜMMEL. *Autogene Metallbearbeitung,* Vol. 29, June 15, 1936, pages 182-183. Examples illustrate possibilities and artistic effects obtainable in decorative arts. Ha (7b)

Welding in Strip Mill Practice. J. SELWYN CASWELL. *Sheet Metal Industries,* Vol. 10, Apr. 1936, pages 327-329. The welding of rolled strip to increase the weight of coils or to maintain the continuity of movement through the processing stages is discussed. Fabrication and maintenance of plant are treated to show the possibilities for the increased use of welding. AWM (7b)

The Oxwelding of Non-ferrous Metals and Stainless Steel. W. A. DUNCAN. *Iron & Steel of Canada,* Vol. 19, June 1936, pages 5-11. Welding of non-ferrous metals and their characteristic behavior in welding is discussed at length, it is emphasized that the more numerous metals and alloys become used in modern industry the more important it is that they possess good weldable properties as welding must be considered just as useful a tool to the non-ferrous artisan as it is to the steel manufacturer. Al, brasses, bronzes, Monel metal, stainless steels are treated individually; the beneficial effects of Co and Ti as addition elements to the welding rod for prevention of intergranular corrosion are explained. Ha (7b)

Classification of Welders (La Classification des Soudeurs) *Revue de la Soudure Autogène,* Vol. 28, June 1936, page 2. Necessity for classification of welders results from recent social movement which wishes to establish wage rates for different kinds of labor. FR (7b)

Application of New Oxy-Acetylene Welding Methods (L'Application des Nouvelles Méthodes de Soudure Oxy-Acétylénique) *Revue de la Soudure Autogène,* Vol. 28, Mar. 1936, page 6. Application of hand and machine welding by the double seam process in the manufacture of pressure vessels. FR (7b)

Review of Technical Literature on Fusion Welding (Revue de la presse de la Soudure Autogène) J. FASSBINDER. *Bulletin de la Société des Ingénieurs-Soudeurs,* Vol. 7, Mar.-Apr. 1936, pages 2153-2163. Lecture before the French Welders' Society. Reviews typical applications of welding. FR (7b)

Foreign Countries Lead U. S. in Welded Bridges. LA MOTTE GROVER. *Engineering News-Record,* Vol. 116, May 14, 1936, pages 703-709. A review of European accomplishments of the last 5 years shows that many structures have been welded of which there are no counterparts in American practice. CBJ (7b)

Welding Methods for the Non-Ferrous Metals. H. W. G. HIGNETT. *Metal Industry,* London, Vol. 48, Jan. 17, 1936, pages 92-98. The author compares the welding of non-ferrous metals with that of ferrous metals. He lists, in order of importance, as factors which influence the choice of welding process for non-ferrous metals: (1) metallurgical, (2) thermal, and (3) economic. Available methods discussed are (a) oxy-hydrogen and oxy-coal gas, (b) oxy-acetylene, (c) C arc welding, (d) metallic arc welding, (e) atomic H welding, (f) electric resistance spot and seam welding, and (g) butt and flash welding. 32 references. HBG (7b)

Welding of Boilers of the Steamer "France" (Les Soudures des Chaudières du Paquebot "France") MAURICE LEBRUN. *Bulletin de la Société des Ingénieurs-Soudeurs,* Vol. 7, Mar.-Apr. 1936, pages 2131-2133. Lecture before the French Welders' Society. Short descriptive account. FR (7b)

Some Applications of Welding in the Works of the French "Orleans" Railway Company (Quelques Applications de la Soudure dans les Ateliers de la Compagnie d'Orleans) R. LABORIE. *Bulletin de la Société des Ingénieurs-Soudeurs,* Vol. 7, Mar.-Apr. 1936, pages 2091-2121. Lecture before the French Welders' Society. Study is made of: (1) Electric arc welding; among examples given is the complete welding of a steel firebox and the repair of a locomotive frame, (2) welding using both arc and torch welding; examples given comprise repair of a cast Fe cylinder and complete building up of a locomotive cylinder, (3) electric resistance welding; typical examples for part manufacture such as connecting and piston rods as well as for tool reclaiming and frame work construction are reviewed. Last section deals with installation of welding shops and with training of welders at the "Orleans" Company. FR (7b)

A Few Considerations for Further Research on Low-temperature Steel Welding. E. LEWIS. *Iron & Coal Trades Review,* Vol. 132, June 26, 1936, page 1156. A new welding process is described based on the fact that the higher the C content of a steel, the lower will be its melting point. A special patented type of welding blowpipe is used the tip of which has 2 additional preheating flames situated about half way up the nozzle which are to prepare the joint for the actual welding operation. The necessary C to lower the melting temperature of the surface is obtained by an excess of acetylene in the flame. Tests showing the very good mechanical properties of such welds are described. Ha (7b)

Fusion Welding in Railway Shop (La Soudure Autogène dans les Ateliers des Compagnies de Chemins de Fer) R. MESLIER. *Revue de la Soudure Autogène,* Vol. 28, Mar. 1936, pages 2-5. It is said that manufacturing shops of railway companies are now using very intelligently all the welding processes. Cu and steel fire-box manufacture is described and abundantly illustrated. FR (7b)

Welding of Rails on the Permanent Way. M. MICHAUD. *Iron & Coal Trades Review,* Vol. 132, June 26, 1936, page 1158. Welding methods used at present for the maintenance of railroad tracks are reviewed and compared. Ha (7b)

Welding of Rail Tracks (La Soudure des Rails) JEAN NÈGRE. *Bulletin de la Société des Ingénieurs-Soudeurs,* Vol. 7, Mar.-Apr. 1936, pages 2135-2152. Lecture before the French Welders' Society. Operations are conducted as follows: (1) Bottom and upper surfaces are cleaned, (2) rails are set in position, (3) weld is made, (4) power is maintained during a predetermined time in order to decrease brittleness of metal, (5) cleaning is performed by compressed air chisel, (6) upper part is finished by a special hot cutter, (7) grinding is then resorted to, using a portable compressed air grinder, (8) 2 workers can handle 60 m. rail length without difficulty. FR (7b)

The Welding School of the French State Railways at Le Mans (L'Ecole de Soudure des Chemins de Fer de l'Etat au Mans) PIERRE ROSEMBERG. *Revue de la Soudure Autogène,* Vol. 28, May 1936, page 13. Brief data about the school. FR (7b)

Resistance Welding the Light Alloys. R. SALELLES. *Metal Industry,* London, Vol. 47, Nov. 15, 1935, pages 489-493. Article is translated from *Revue de la Soudure Autogène.* The author gives details of a resistance welding process recently developed in France. He describes results obtained by Sciaky Electric Welding Machines, Ltd. in welding of Al, Duralumin, Vedal, etc. The general theory of resistance welding is briefly discussed. The special machines believed necessary for spot-welding Al and its alloys are described, methods of their operation are discussed and reasons suggested for certain requirements. The advantages of this type of welding are emphasized. The article is illustrated. HBG (7b)

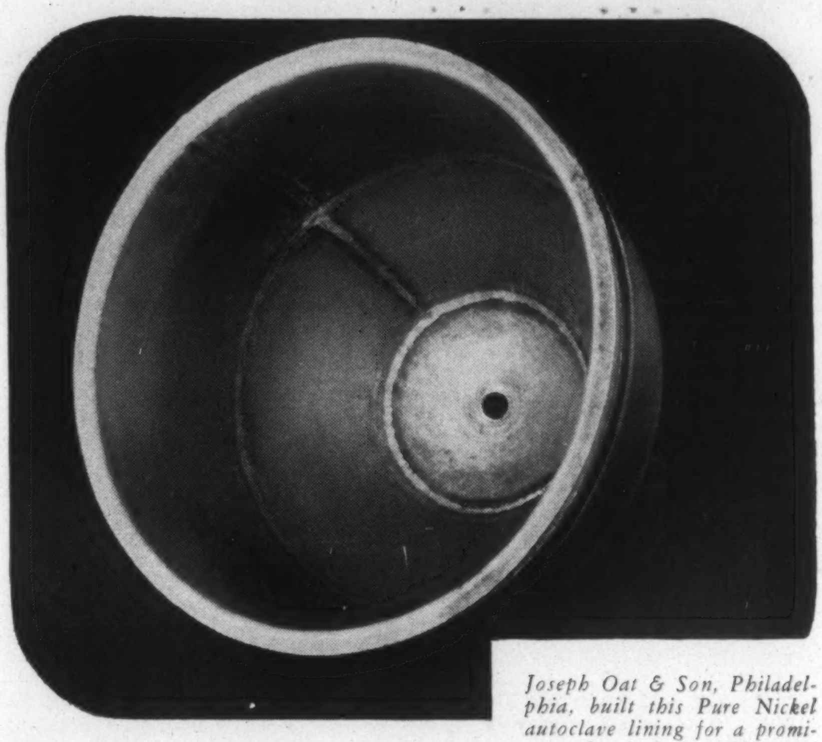
At the Paris Show (A la Foire de Paris) R. SALELLES. *Revue de la Soudure Autogène,* Vol. 28, June 1936, pages 3-9. Describes and illustrates new welding appliances and machines as seen at the recent Paris show. FR (7b)

High Pressure Arcs. C. G. SUITS. *General Electric Review,* Vol. 39, Apr. 1936, pages 194-200. Characteristics, temperatures, thermal equilibrium, and current conduction of arcs including welding arcs are discussed. CBJ (7b)

HOW DID THE MAKERS

WELD

THIS NICKEL LINING?



Joseph Oat & Son, Philadelphia, built this Pure Nickel autoclave lining for a prominent chemical plant. This shell is 48" dia. x 40" deep, made of 1/8" thick standard Nickel sheet with all joints gas welded, using Inco Nickel Gas Welding Wire No. 41. This is typical of welded Nickel linings for many types of chemical and food processing equipment.

Without a flux . . . With Inco gas welding wire No. 41 . . . With a tip one size larger than for steel

HERE'S a neat job—an autoclave lining of Pure Nickel, gas welded. A chemical plant needed the strength, the toughness and corrosion resistance that Nickel gives . . . and welding furnished the answer to "How Build the Machine."

When you need Nickel or Monel in one of your machines, remember these metals can be welded. And by all the methods commonly used on steel.

Any good welder can handle Monel and Nickel as easily as steel . . . only he must handle them differently from steel. The little details of difference that matter he must know.

For instance; in the job shown here the welder used no flux. That's because he was welding Nickel, and a flux with Nickel can cause brittleness. But to weld Monel, you should use a flux, to avoid discoloration and to improve fluidity.

The answer is, write Inco, and ask for "Technical Bulletin T-2," which gives full instructions for welding these two metals. You can have your replacements fabricated right in your own plant if you wish. Ask us for the name and address of the fabricator nearest you.

THE INTERNATIONAL NICKEL COMPANY, INC.
67 WALL STREET NEW YORK, N. Y.

NICKEL

Monel is a registered trade-mark applied to an alloy containing approximately two-thirds Nickel and one-third copper. This alloy is mined, smelted, refined, rolled and marketed solely by International Nickel.

MONEL

Multiple Arc Welding Sets. C. J. Holslag. *Welding Journal,* N. Y., Vol. 15, June 1936, page 23. Note on space saving and other economies in use of multiple arc instead of set for each man or each operation. WB (7b)

Gas-fusion Welding of Special Workpieces (Gasschmelzschweissung besonderer Werkstücke) W. Hönisch. *Autogene Metallbearbeitung,* Vol. 29, June 15, 1936, pages 181-182. Examples of a ship's anchor and the jaws of a rock crusher which were repaired by autogenous welding are described. Ha (7b)

Inspection of Welded Seams in Pressure Vessels. W. D. Halsey. *Welding Journal,* London, Vol. 33, Mar. 1936, pages 78, 80. See *Metals & Alloys,* Vol. 7, June 1936, page MA 299L/1. WB (7b)

Autogenous Welding in Railway Material (La Soudure Autogène dans le Matériel de Chemin de Fer) Laborie. *Usine,* Vol. 45, Apr. 23, 1936, pages 29-31. Practices in French railway shops are described; particular attention is paid to training of personnel. Ha (7b)

Low Alloy, High-Tensile Steels. A. B. Kinzel. *Welding Journal,* N. Y., Vol. 15, May 1936, pages 24-27. Review of desirable physical properties of low alloy steels, combining good ductility and high strength. The various alloys are grouped and their effect on hardening propensity and grain growth susceptibility of the alloy steel during welding indicated. Weldability of the steels are discussed from engineering viewpoint and the metallurgical quality of the various sections of the transition zone next to the weld bead detailed. Zone of largest grains is not considered to be a dangerous structure due to short duration of weld heat. Zone of recrystallization considered to be a dangerous one due to heating to austenite range and rapid quench. WB (7b)

Arc Welding Apparatus. E. Steinert & W. W. Reddie. *Iron & Steel Engineer,* Vol. 13, Jan. 1936, pages 9-12. Welder is described incorporating advantages of main contactor on primary side with a smaller contactor, operators are not required to hold in the control switch while welding, control starts with button switch, load loss negligible and welding terminals are automatically de-energized when welding ceases which increases safety. WLC (7b)

Present Status of Electric Welding in Germany (Der heutige Stand der Elektroschweissung in Deutschland) K. Siemers. *Elektrowärme,* Vol. 6, June 1936, pages 195-198. Particular progress was made in the butt-upset resistance welding process for small parts, wires and non-ferrous metals. Machines operating entirely automatically are made now for sections up to 25,000 mm.^{2} and for spot-welding with about 200 points/min. for sheets of 3-4 mm. thickness. Ha (7b)

The Nature of Fluxes and Their Effect on Weld Metal. T. C. R. Shepherd & M. R. Moritz. *Sheet Metal Industries,* Vol. 9, Nov. 1935, pages 721-722; Dec. 1935, page 788. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 129L/10. AWM (7b)

Welding of a Preheated Cast Iron Cylinder (Gusseisenwarmschweissung eines Zylinders) Scholz. *Autogene Metallbearbeitung,* Vol. 29, June 1, 1936, pages 171-172. The procedure used in repairing a crack of 1000 mm. length is described in detail. The cylinder was preheated by charcoal fire to red heat and welded with the oxy-acetylene flame, and then slowly cooled in about 60 hrs. Ha (7b)

Fabrication of Cast and Rolled Steel. J. M. Sampson. *Transactions American Foundrymen's Association,* Vol. 7, Apr. 1936, pages 351-366. Tests were made to obtain physical data for welded joints of cast steel to cast steel, cast steel to hot rolled steel, either as bar or platestock, and cast steel to cold rolled steel. The cast steel used in these tests varied in C content from 0.31 to 0.39% and the rolled steel was the usual material available in the factory. Most of the joints were arc welded by the use of bare electrode, type L, and fluxed electrodes, types W-20 and W-21. Some joints were flash welded. 4 general types of tests were used: Tension, shear, bending, and fatigue. It was concluded that cast steel may be welded to cast steel or to rolled steel either by arc welding with fluxed electrodes or by flash welding regardless of the character of surface preparation, with entirely satisfactory results. While annealing reduces the tensile strength, it increases ductility, and the best results are obtained when heat treatment is applied after the structure is completely welded. All specimens of cast steel welded to plate stock failed in plate stock with all types of electrodes. CEJ (7b)

Tests on Welded Silicon Steel. M. R. Taylor & Jonathan Jones. *Welding Journal,* N. Y., Vol. 15, May 1936, pages 31-33. Analysis of steels of unknown weldability which were used as deck plating for part of Triboro bridge showed:

	C	Mn	Si	P	S
plates	.29	1.0	.23	.013	.024
7″ beams	.27	.95	.26	.020	.035

Good weldability was shown in tests which are described and discussed. WB (7b)

Thermit Welding under Traffic. John B. Tinnon. *Transit Journal,* Vol. 80, June 1936, page 166. Thermit welding under traffic may be accomplished by the insert method or by the undercut method. In the insert method an insert cut from a piece of rolled rail steel is placed between the rail heads at the running surface, while in the undercut method a gap is cut in the webs, bases and lips of the rails and the overhanging ends of the rail heads form an attached insert and are butt welded together. 17 steps of effecting the weld are listed. WHB (7b)

7c. Riveting

Concerning the Use of Pneumatic Riveting Hammers. *Compressed Air Magazine,* Vol. 41, Apr. 1936, page 5013. Manual riveting is most desirable when less than 50 rivets are to be driven; pneumatic equipment should be used for more than 100. Method used for intermediate jobs depends on individual conditions. FPP (7c)

Riveting Aluminium. A. J. T. Eyles. *Aluminium & the Non-Ferrous Review,* Vol. 1, Apr. 1936, page 329. Workshop notes. JCC (7c)

8. FINISHING

H. S. RAWDON, SECTION EDITOR

Metallurgical Progress and the Finishing Industry. *Synthetic & Applied Finishes,* Vol. 6, Feb. 1936, pages 265-266, 287. Metallurgical developments affecting the finishing industry in 1935 are reviewed. Electrodeposition of Zn from solutions obtained by leaching roasted Zn ore; improvement in electrodes for welding mild steel plate; plating of metals on nonmetals; bright annealing developments; electrodeposition of Re, Te and Cd-Zn; hard-facing of metals for superior abrasion resistance; Ni clad steel, mirror finished automotive cylinder barrels, and metallizing, are each briefly discussed. FPP (8)

8a. Pickling

Pickle Pitting by Electrolytic Potentials as Affected by Scaling Temperature. C. H. McCollam & D. L. Warrick. *Transactions American Society for Metals,* Vol. 24, Mar. 1936, pages 133-153; *Heat Treating & Forging,* Vol. 21, Oct. 1935, page 484. Paper and discussion from the Chicago Convention of the Society, 1935. Data are presented to show that pitting during pickling is associated with electrolytic action between scale and metal. Potential of scale was found to be a function of scaling temperature. At lower temperatures the potential is practically the same as that of the metal and pitting is absent, but at higher temperatures the difference in potential is marked and deep pitting is likely to occur. The boundary between these temperature ranges roughly coincides with the transformation temperature. Mechanical scale breaking before pickling tends to lessen depth of pickle pits. Inhibitors modify the electrolytic action but do not prevent deep pitting. WLC + MS (8a)

Equipment for Wide Strip Pickling System Rubber Lined. *Steel,* Vol. 98, May 11, 1936, pages 53-54. Equipment in River Rouge plant of Ford Motor Co. handles strip up to 78″ in width. There are 2 240-ft. lines of welded steel tanks, lined with rubber which is covered with inner lining of acid-proof brick jointed with special S-base cement. Pb siphons are used for emptying tanks into steel sewer. Strip is supported between tanks by steel carrier rolls, under which are steel drip-pans. All acid tanks have sectional, flanged steel covers. Steel ducts carry fumes from center of each tank to H_2O spray tanks, in which countercurrent washing and cooling of fumes remove all acid. All steel equipment is rubber lined. MS (8a)

Inhibitors in Pickling. P. R. Russell. *Journal American Zinc Institute,* Vol. 17, 1936, pages 81-87. A good inhibitor must give a bright finish free from non-rinsable discolorment, stain, or film. It should maintain satisfactory inhibition throughout the life of the pickling bath. Many inhibitors give high initial inhibition but the action drops off sharply in a very short period. No obnoxious odors or fumes should be given off, and the inhibitor should not cake in shipping containers. An inhibitor must be easily soluble and should not be so active that the action of the acid on the scale is slowed up enough to impair operating schedules. A moderate passivating effect is desirable to prevent discoloration during exposure between pickle and rinse. A good inhibitor results in an overall reduction of 30 to 40% in acid consumption. Under ideal pickling conditions and by proper use of inhibitors the acid consumption should be about 90 lbs./ton of 26 gage sheet. Most inhibitors are complex organic compounds. BHS (8a)

8b. Cleaning including Sand Blasting

Cleaning Before Plating. Terrence A. O'Neil. *Metal Progress,* Vol. 29, June 1936, pages 59-64. Description of cleaning methods and discussion of the importance of thorough cleaning in preparation for electroplating of metal parts. WLC (8b)

Diluents and Solvents used in Industry, and Their Physiological Effects (Os Solventes empregados na Industria, e seus Effeitos physiologicos) C. E. Nabuco de Araujo, Jr. *Revista Brasileira de Chimica,* Vol. 1, June 1936, pages 251-252. The toxicity of diluents and solvents used in painting, electroplating and cleaning processes are reviewed, and the amounts of vapor in the air seriously affecting health are tabulated for benzine, carbon tetrachloride, gasoline, chloroform, and other hydrocarbons. Ha (8b)

8c. Polishing & Grinding

Canadian National Grinds Driving Axle Journal. M. M. McCall. *Iron Age,* Vol. 137, May 14, 1936, pages 37-42. Describes method and equipment used by the Canadian National Railways in grinding journals on locomotive driving axles. Burnishing is still the accepted practice in the United States. Grinding is done on 90″ combination journal turning and grinding machine. Advantages claimed for grinding; (1) more accurate and better finish; (2) greater freedom from hot boxes; (3) material increase in life of axle; (4) 125,000 miles of operation without grinding of journals; and (5) increased production. VSP (8c)

Surface Grinding in the Tool Room. Fred B. Jacobs. *Abrasive Industry,* Vol. 17, May 1936, pages 11-15. Errors in grinding due to wheel wear have been reduced. Many types of surfacing grinders are shown for large and small jobs and their operation briefly described. WB (8c)

8d. Electroplating

Bright Deposition of Cobalt. A. Chaybany. *Electrometallurgy,* supplement to *Metal Industry,* London, Vol. 48, June 26, 1936, pages 721-722. On the basis of the theory that matte deposits are composed of metal containing traces of hydroxide or basic salts and that bright deposits are purer metal, the author studied the problem of bright deposits of Co. This required (1) the prevention of the precipitation of $Co(OH)_2$ or (2) the suppression of the evolution of H. The former may be accomplished by acidifying the bath, the addition of acid alcohols or organic polyalcohols, or the regeneration of acidity at the cathode by reduction of the SO_4-ion. In a bath composed of :

Cobalt-ammonium sulphate	200.00 grams,
Pure H_2SO_4	10.00 grams,
Hydroquinone	.20 grams,
Sodium hydrosulphite	.05 grams,

the deposits obtained were sufficiently bright that subsequent polishing was unnecessary. Suppression of the evolution of H was attempted by introducing into the bath salts of metals having higher over-voltage such as Hg, Zn, Cd, and Sn, and also certain commercial inhibitors such as colloids, aldehydes, formaldehyde, derivatives of thio-urea and of quinoline. White deposits of Co were obtained with these inhibitors but none were as satisfactory as that obtained in the presence of hydroquinone and of Na hydrosulphite. In a bath containing a metal of high over-voltage and one of these inhibitors, deposits of mirror-like brilliance were obtained. For depositing Co at temperatures below 25° C., the author uses a bath of the following composition:

Cobalt-ammonium sulphate	200.00 grams
Neutral ammonium acetate	30.00 grams
Free acetic acid	1.00 grams
Formaldehyde	3.00 grams
Cd sulphate	0.2 grams
Water	1 liter

For plating at higher temperatures the Cd sulphate must be increased. HBG (8d)

Adventures in Electroplating Copper from Ammoniacal Solution. E. A. Vuilleumier. *Monthly Review American Electroplaters' Society,* Vol. 23, Feb. 1936, pages 44-50. By electrolyzing a solution containing 25 g. $CuSO_4.5H_2O$, 60 cc. conc. NH_4OH in 1 l. H_2O at 6 milliamps./cm.^{2}, a dense, bright, satisfactory Cu deposit resulted. When the cell was allowed to stand overnight and then electrolyzed, a coarse, loose, moss-like deposit of Cu crystals was obtained. This change in behavior was attributed to the fact that Cu anode was allowed to remain in solution. Cuprous oxide was formed which produced a film on the cathode, which, it is thought, was discontinuous. Cu electrodeposited through the holes in the film gave rise to the spongy deposit. Remedy consisted in adding excess conc. NH_4OH, or $(NH_4)_2SO_4$ plus dilute NH_4OH to the solution. Cuprous oxide was then dissolved and good deposits were again obtained. GBH (8d)

The Basic Theory of the New "Bethanizing" Process. U. C. Tainton. *Wire & Wire Products,* Vol. 11, May 1936, pages 225-227, 243. "Bethanizing" is a process of electro-depositing very pure Zn (99.9975%) on Fe or steel. It is plated onto the steel directly without the use of an intermediary Al cathode. The raw material is a roasted Zn concentrate of 50-60% Zn, in which are present also Cd, Cu, Pb, Ag and Au; Fe, Ni, Co and Mg; Al, Ga, In, and Th, Si and Ge, As and Sb, O, S, Te; Mg, Ca, Cl and F. The electrolyte carries about 250 g./l. of free H_2SO_4. During the first stages of operation most of the foreign elements pass into solution, and with continued addition of Zn-bearing material the acid concentration diminishes and gradually approaches neutrality. The reactions up to this point which are complex are described at length. The deposition of Zn at this stage is possible but only by applying an overvoltage in order to utilize the property of Zn to oppose the development of H under this condition. A new pickling method developed for steel consists in use of a fused salt bath (NaOH) to avoid occlusion of H in the steel and to obtain the absolutely clean surface required. Electrolysis is carried out at current density from 700 to 2000 amp./ft.^{2} The anodes consist of a Pb-Ag alloy. Special polishing and densifying dies were developed for the Zn coating. The whole process as developed in the Bethlehem Steel Co. is described in full. Ha (8d)

8e. Metallic Coatings other than Electroplating

Some Practical Aspects of Galvanizer Dross at High Temperatures. *Iron & Steel of Canada,* Vol. 19, Feb. 1936, pages 11-12. The sources of Fe accumulating in galvanizing baths are discussed. The Zn usually contains less than 0.08% Fe; the latter is carried into the bath of molten Zn by Fe salts from pickling and by corrosion of the Fe surface when drying after pickling. The dross changes in character when the pot is at high temperature; in some cases the temperature has been so high (1000°-1500° F.) that the dross is entirely crystalline in texture, called "sandy." The proper bath temperature and galvanizing conditions will always produce a dross that has the long, slender, needle-like rhombohedral form of crystal and such conditions also assure longer life of pots and better operating conditions. Ha (8e)

Surface Protection Symposium and Exhibit of Surface Protection Technique in Austria (Oberflächenschutz-Tagung und Ausstellung "Oberflächenschutztechnik in Österreich") *Montanistische Rundschau,* Vol. 28, June 16, 1936, 4 pages. A review of a meeting and exhibit held at the Montanische Hochschule in Graz-Leoben, Austria, May 7-9, 1936. Deals mainly with galvanizing, parkerizing, the Schoop metal-spraying process, and enamelling. Very little new information is given. BHS (8e)

Cementation with Beryllium (La cementation par le glucinium) J. Laissus. *Métaux,* Vol. 11, Mar. 1936, pages 48-59. See *Metals & Alloys,* Vol. 7, June 1936, page MA 304R/4 and Vol. 6, Mar. 1935, page 120R/8. GTM (8e)

The Metallization of Machine Elements. W. E. Glidden.* *Iron Age,* Vol. 137, Apr. 9, 1936, pages 49-51, 132; Apr. 16, pages 31-33, 53. Describes metal spraying of machine elements which must subsequently stand up under grinding and machining operations. The porosity of sprayed coating which is considerably greater than that of hot-dip or electroplated coatings may be overcome by mechanical, thermal or chemical means. Surface preparation, blasting with steel grit or sand, before spraying, is of greatest importance. Surface coating must be applied right after cleaning. Second instalment gives results of tests on adhesion of coating, effect of heat treatment, resistance to corrosion and limitations of process in coating small pipes. Order of resistance to corrosion of coatings tested i:s (1) Zn; (2) Cd; (3) Al; (4) Sn; (5) stainless steel; and (6) Cu. VSP (8e)

8f. Non-Metallic Coatings

Reaction Between Paint Films and Zinc Surfaces. Henry J. Wing. *Industrial & Engineering Chemistry,* Vol. 28, Feb. 1936, pages 242-243. This study shows definitely that reactions can take place between Zn surfaces and the oxidation products formed in the drying of oil or varnish type finishes. Compounds formed as a result of this reaction are actually present on paint films which peel from galvanized surfaces. Zn formate has been definitely identified as one of these compounds. Presented before the Division of Paint and Varnish Chemistry at the San Francisco Meeting of the American Chemical Society, Aug. 1935. 20 references. MEH (8f)

Improved Coatings for Duralumin. Herbert Chase. *Aero Digest,* Vol. 28, May 1936, page 40. Brief resume of some tests on anodic film, paint, lacquer and pigment coatings on duralumin. Specimens remained in 20% salt spray without failure for more than 4700 hrs. Best coating is paint vehicle with Al powder. WB (8f)

Highly Heat-Resistant Anti-Rusting Finishes. F. J. Peters. *Synthetic & Applied Finishes,* Vol. 6, Dec. 1935, pages 230-232, 235. Complete, detailed discussion of comparatively heat-resistant, rust-inhibiting coatings for steel. Optimum combination of rust-protecting vehicle and heat-resistant pigment is difficult to select and produce. A vehicle that merely turns brown or burns away completely at an elevated temperature is practicable; charred coatings are unsuitable. Between 300° and 400° C. low-oil rosin or ester gum varnishes that burn away and synthetic resin (e.g. durophene) that is scarcely affected are suitable. Practically, only white and black pigments remain unchanged in color at high temperatures, although Cd red, green Cr oxide and burnt umber are unaffected at 400° C. Best all-around qualities are offered by Al powder or Zn dust in a vehicle that completely burns away. Al is believed to form a compound with Fe at the surface; above 700° C. "calorizing" occurs but rust protection is decreased. Metal-pigment paints do not afford perfect rust protection but the combination of heat and rust resistance is satisfactory. The advantages of multiple-coat finishes are discussed. FPP (8f)

Down here in Maryland where
THE HORSE IS KING

FLYING hoofs roll out a fast tattoo that quickens the pulse of the wildly cheering throng on tip-toe in its excitement. Maryland's racing season is on! —and your home in Baltimore is ready for you.

Your car is taken at the door by an expert garage attendant. Yours is one of 700 comfortable rooms—each with bath and shower, running ice water, full length mirror and bed head reading lamp. You're at the center of Baltimore's business and social activities. You enjoy characteristic Maryland cuisine in any of three distinct restaurants. And the rate—from $3.00 single.

9. TESTING

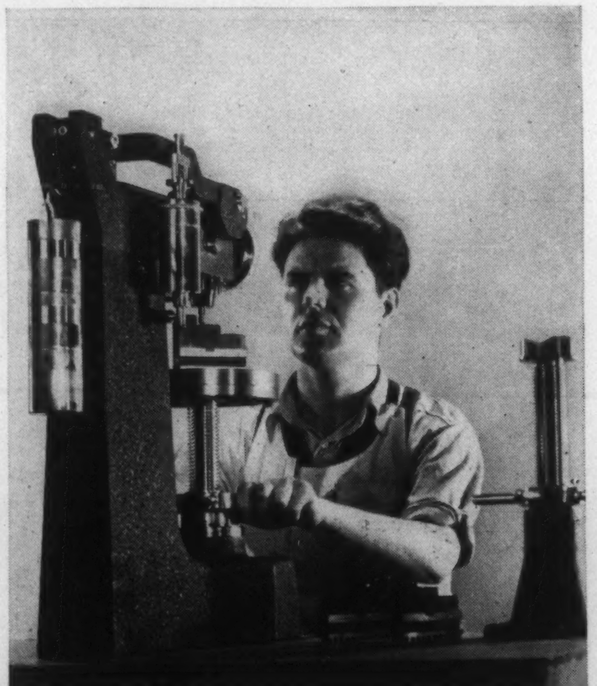
Testing Steels by Sparking. De Bary Kerston. *Scientific American,* Vol. 154, Mar. 1936, page 125. Increase in C content increases the "bursts" on sparking. Mo gives an orange colored spear at the end of every carrier line. Ni gives tiny blocks of brilliant white light. Si suppresses the C spark. High W steels give a dull red spark. CBJ (9)

9a. Inspection & Defects, including X-Ray Inspection

C. S. BARRETT, SECTION EDITOR

Scale for Estimation of Slag Inclusions in Iron and Steel (En skala för bedömning av slagginneslutningar i järn och stål) Bertil Rinman, Hans Kjerrman & Bengt Kjerrman. *Jernkontorets Annaler,* Vol. 120, June 1936, pages 199-226. The scale adopted by the Swedish Ironmasters' Association is described. It consists of a series of micrographs showing various typical fields of view, arranged in groups (A, B, C, D) with regard to form and distribution of inclusions, and numbered (1, 2, 3, 4, 5) according to quantity. In applying this method a micrograph of the specimen is compared with a micrograph of the scale. The actual diameter of the field of view must be 0.8 mm. and the magnification 100 diameters when a focusing screen is used. Without such a screen a magnification of 150 diameters is required. The scale in full size (80 mm. diameter) with complete description in English, French, or German can be obtained from Jernkontoret, Stockholm 16, Sweden. HCD (9a)

X-ray Stress Measurements on Quenched Steel Shafts (Röntgenographische Spannungsmessungen an abgeschreckten Stahlwellen) F. Wever & H. Möller. *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Düsseldorf, Vol. 18, No. 3, 1936, pages 27-30. The lattice constants of the material were determined by vertically incident X-rays and then the accuracy of the derived stresses compared with mechanical measurements (by boring out layers from the shaft by the Sachs method). The 2 methods give different absolute values for the stresses, but agree as to change in stress during the boring out process. This results from additional stress (tensional, 40 kg./mm.^{2}) extending about 0.2 mm. below the outer surface, which are measured by the X-ray and not by the mechanical method. When the stressed layer is etched off the methods agree. Ha + CSB (9a)



That's the way it should be!

We use the very finest quality of machine tools and small tools to build the "ROCKWELL" Hardness Tester. The "ROCKWELL" in turn helps the builders of fine machine tools and small tools to maintain their quality.

Examination of Metal Coatings for Porosity. I, II, III. Nathaniel Hall. *Platers' Guide,* Vol. 32, Mar. 1936, page 12; Apr. 1936, pages 13-14; May 1936, page 30. Rough chemical tests for porosity are based on 2 reactions: (1) involves the selective corrosion of the basis metal at the pore and its solution in the testing reagent, and (2) involves either displacement of gas or another metal from the solution, or the reaction of the dissolved basis metal with one of the constituents of the solution to form a colored pigment. The $CuSO_4$ test for Cr plate, the dimethylglyoxime test for Cr plate and the ferroxyl test for coatings on Fe and steel are outlined, as well as the so-called Frigidaire solution test and tests for Ni on brass and Cu. The Frigidaire test depends upon the fact that trichloracetic acid will dissolve Cu. Zn and Al coatings may be tested by immersion in either acid or alkaline solution. For Zn a warm 25% NaOH solution or a .25% HCl solution (by volume) may be used. For Al a 5% NaOH or a 5% HCl solution is advisable. WHB (9a)

Iron Oxide Printing. Roland Mitsche. *Metal Progress,* Vol. 29, Mar. 1936, page 69. Describes method of printing oxide inclusions on gelatine paper moistened with dilute HCl and developed with $K_4Fe(CN)_6$ solution. See also "Detection of Oxide Inclusions in Steels by Imprint Methods," *Metals & Alloys,* Vol. 7, June 1936, page MA 307L/1. WLC (9a)

Difficulties in Determining the "Physical Purity" of Steel. Albert Portevin. *Metal Progress,* Vol. 29, May 1936, pages 68-69. Use of examination of polished surfaces for determination of physical purity is dependent on the human factor and the usefulness is limited to employment by the same operators in one plant. WLC (9a)

Ultra Sound Waves for Locating Inner Defects. B. M. Suslov. *Metal Progress,* Vol. 30, July 1936, pages 60-61. Supersonic vibrations from the inverse piezoelectric effect in quartz due to the application of high frequency alternating voltage are used. Ripples in oil or Hg caused by waves passing undamped through the material may be photographed. Such photographs provide a map of inner defects. WLC (9a)

Testing Materials for Railway Use. R. K. Linach. *Iron & Steel of Canada,* Vol. 19, Feb. 1936, pages 13-16. Methods used by Canadian railroads are described. Ha (9a)

Flakes in Steel Forgings. *Metal Treatment,* Vol. 2, Spring 1936, pages 14-16, 23. Abbreviated translation of two papers from *Revue de Métallurgie.* See "Formation of Flakes in Chromium-Nickel-Molybdenum Steels," *Metals & Alloys,* Vol. 7, Apr. 1936, page MA 197L/5, and "Flakes in Forged Steel," *Metals & Alloys,* Vol. 7, June 1936, page MA 286R/7. JCC (9a)

Flakes in Forging Caused by Hydrogen. I. Musatti & A. Reggiori. *Metal Progress,* Vol. 30, July 1936, pages 51-56. See *Metals & Alloys,* Vol. 7, Apr. 1936, page MA 197L/5. WLC (9a)

Controlled Welding in Boiler Making (La Soudure Controlée en grosse chaudronnerie) R. Lemaire. *Usine,* Vol. 45, Mar. 26, 1936, page 29. Methods are reviewed for testing welds in large boilers during welding operations where destruction test methods cannot be employed. Radiography is most satisfactory as even very small defects, inclusions and blisters are easily detected. Bending tests with welded boiler plate specimens can also be employd. The method is described. Ha (9a)

X-ray Measurement of Elastic Stresses (Röntgenographische Bestimmung elastischer Spannungen) W. E. Schmid. *Archiv für Technisches Messen,* Vol. 5, May 1936, page T57. Description of absolute determination of elastic stresses without destroying the piece, by X-rays directed onto the surface and diffracted. The X-ray photograph indicates the deformation in the direction of the primary beam from which the stresses at the irradiated place can be determined. 7 references. Ha (9a)

X-ray Stress Measurements on Welded Structures (Beitrag zur röntgenographischen Spannungsmessung an geschweissten Bauwerken) F. Wever & Ad. Rose. *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Düsseldorf, Vol. 18, No. 3, 1936, pages 31-33. Measurements with X-rays on fabricated I-beams showed all over the surface high compressive stresses which, however, were not caused by the welding process. They originated in the rolling of the original profiles used to make up the beams and were increased by the straightening process. These stresses are restricted to the surface and penetrate about 0.5 mm. Ha (9a)

Methods of Determination of Radioactivity in Solid, Liquid and Gaseous Substances (Methodos de Determinacao da Radioactividade dos Corpos Solidos, Liquidos e Gazosos) A. Leal. *Revista Brasileira de Chimica,* Vol. 1, Apr. 1936, pages 137-140. Principles and instruments, and application for industrial purposes are described. Ha (9a)

Prevention of Injuries by Radiation in Testing of Materials by Mesothorium and Radium (Die Verhütung von Strahlenschädigungen bei Werkstoffprüfungen mit Mesothor und Radium) W. Friedrich & W. Noethling. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, Apr. 11, 1936, pages 437-440. The sources and kinds of serious injuries when testing materials with radioactive substances are explained and preventive means and equipment described. Ha (9a)

Defects in Steel (Fehler im Stahl) R. Scherer & W. Zieler. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80. June 13, 1936, pages 751-754. The principal defects in steel can be due to defects in the melting and casting process, defects in hot and cold working, defects in heat treatment of the finished steel, and defects due to wrong selection and application of tools. These conditions are discussed at some length. 13 references. Ha (9a)

Impact Test Piece with 2 mm. Notch Best for Alloy Steel. Federico Giolitti. *Metal Progress,* Vol. 29, May 1936, pages 71-72. Data presented indicate that a 2 mm. notch is superior to 3 or 5 mm. notches for impact specimens. WLC (9b)

Determination of Strains in a Welded Seam by Means of Photo-elasticity (Sobre la determinacion de tensiones en un cordon de soldadura por la fotoelasticidad) J. Bech Argeles. *Metalurgia y Construccion Mecanica,* Vol. 2, July 1936, page 6. This instalment deals with the determination of strains in a welded seam. 15 references. FRM (9b)

Evaluation of Toughness Under Low and High Speed Loadings. Robert S. Rose. *Metal Progress,* Vol. 30, July 1936, pages 61-62. From work and discussion of this subject the writer presents the conclusions that static or low speed tests are unreliable as indexes for applications under really high speeds, that tests allowing separate evaluation of the several mechanical properties are helpful, and that both static and high speed tests are essential to reveal the true capacity of a material. WLC (9b)

Some Tests of Steel Columns Incased in Concrete. Ambrose H. Stang, Herbert L. Whittemore & Douglas E. Parsons. *Bureau of Standards Journal of Research,* Vol. 16, Mar. 1936, pages 265-287. In coöperation with the Bridge Department of the Port of New York Authority, the National Bureau of Standards tested 4 C steel columns incased in reinforced concrete to determine their strength and stiffness. The steel columns were duplicates of columns TC1 and TC2 reported in Bureau Research Paper RP831. The temperatures in the columns were measured during the aging of the concrete. The readings of telemeters attached to the steel members indicated that no appreciable stress in the steel members was caused by the aging of the concrete. When the columns were loaded, the telemeter stresses were always less than the quasi-stress obtained by dividing the load by the cross-sectional area of the steel members. The concrete, therefore, carried a portion of the load. At the column yield strength, the load on the incased columns was 51% greater than the load on the unincased columns. At the final maximum load the load on the incased columns was 42% greater than the load on the unincased columns. WAT (9b)

Accelerated Service Tests of Pintle Bearings. Ambrose H. Stang & Leroy R. Sweetman. *Bureau of Standards Journal of Research,* Vol. 15, Dec. 1935, pages 591-600. Accelerated service tests of pintle bearings with different combinations of materials for the pintles and cups, different pressures, and different conditions of lubrication were made under conditions similar to those which might obtain in practice as to the line of thrust and angle of swing. The bearings were under water during the tests. The tests were made in connection with the dams of the Tennessee Valley Authority. The results indicated that of the materials tested one must be phosphor bronze to give satisfactory service for pressures as great as 2,000 lbs./in.^{2} Pintles of H-monel, M-monel, and S-monel, gave satisfactory service at this pressure with phosphor-bronze cups. Cups of stainless steel, Cr steel, Cr-Ni steel, malleable cast Fe, and Monel alloys were scored badly after only a few cycles when tested under a pressure of 2000 lbs./in.^{2} Al-bronze cups were worn excessively at a comparatively small number of cycles. Phosphor bronze was the only cup material tested in this investigation which gave satisfactory service with a pressure as great as 2000 lbs./in.^{2} A stainless steel pintle and phosphor-bronze cup provided with grooves for water circulation and tested under a pressure of 4000 lbs./in.^{2} withstood more than 288,000 cycles, the number of cycles expected in 20 years' service. WAT (9b)

Prestressing and Serviceability of Bolted Assemblies (Vorspannung und Dauerhaltbarkeit von Schraubenverbindungen) A. Thum & F. Debus. *Mitteilungen der Materialprüfungsanstalt a.d. Technischen Hochschule Darmstadt,* No. 7, 1936, 72 pages. This is mechanical engineering rather than metallurgy. The bolts chiefly used were the German standards grade of steel known as 38.13 of 0.05% C, 0.47% Mn, 0.075% P, 0.05% S, of 61,500 lbs./in.^{2} tensile, 31% elongation (in 5 diameters), 64% reduction of area. After various degrees of tightening of the bolts they were subjected to repeated impact loading, of varying intensities, one being finally applied under which the bolt would be unbroken after 2 million repetitions of stress, so that S-N curves could be drawn. Tensile endurance tests were made on belts with machined and rolled threads, without showing notable advantage for either. A shaft smaller than the threaded portion, preferably with the shaft cold worked, minimizing of notch effect and stress concentration by proper shape of threads and of the nut, and screwing the assembly up to the proper degree of prestress are all considered important in securing a bolted assembly that is secure against fracture. HWG (9b)

Upper and Lower Yield Point. G. Welter. *Metal Progress,* Vol. 29, May 1936, page 69. Addition to discussion in *Metal Progress,* Vol. 29, Mar. 1936, pages 66-67. WLC (9b)

Effect of Temperature on the Maximum Force in Impact Tests (Temperaturens inflytande på maximikraften vid slagböjningsprov) W. Weibull. *Jernkontorets Annaler,* Vol. 120, Apr. 1936, pages 167-183. The tests were made in an alpha pendulum apparatus with standard Charpy specimens 10 x 10 mm. and with a 2 mm. groove. The specimen rested on quartz supports and the impact pressure was measured by the change in electrical resistance. The expended work was measured by standard methods. 3 C steels (0.10-0.27% C) and 2 Cr-Ni steels (0.33% C, 1.32% Cr, 2.46% Ni; and 0.43% C, 0.66% Cr, 1.05% Ni) were tested at temperatures from + 100° to — 180° C. The maximum breaking impact decreases sharply at temperature intervals characteristic of each specimen. When the fracture is due to slippage the maximum impact pressure increases as the temperature is lowered, but when the temperature is lowered to the point where the slippage resistance equals the cohesive resistance the breaking impact is constant. The appearance of the fracture changes sharply at the same time, being characterized as "brittle fracture" at the low temperatures and "tough fracture" at the high temperatures. The Cr-Ni steels become brittle at — 80° C. or lower; the C steels at — 20° to — 40° C. HCD (9b)

An Abnormal Electrical Conductivity in Powdered Tellurium. C. Hawley Cartwright. *Physical Review,* Vol. 49, Mar. 1936, pages 443-448. It was found that Te powder under a pressure of 1000 kg./cm.^{2} had about 10 times greater specific electrical conductivity than that of a single crystal of Te under the same pressure. Momentarily passing an electrical current through the powder under pressure caused its volume to diminish, but also the electrical conductivity was greatly decreased and, in the cases of pure Te, it became almost the same as that of the massive metal. Under a hydrostatic pressure of 20,000 kg./cm.^{2} massive Te increases its electrical conductivity more than 100 times and the rate of increase rises rapidly with pressure. WAT (9b)

Deep-drawing Test for Aluminum. A. G. C. Gwyer & P. C. Varley. *Metal Progress,* Vol. 29, Mar. 1936, pages 82, 84, 86. See *Metals & Alloys,* Vol. 7, June 1936, page MA 308L/7. WLC (9b)

Accuracy of Dynamic Material Testing Machines (Die Genauigkeit von dynamischen Materialprüfmaschinen) E. Erlinger. *Messtechnik,* Vol. 12, June 1936, pages 109-111. The difference in behavior of static and dynamic testing machines is explained. While the accuracy of static calibration is generally ± 1% of the maximum load, the dynamic accuracy depends on the masses set in motion during the dynamic test, their mutual relation, and on the difference between static and dynamic elasticity modulus. These points are discussed with regard to construction of the machine and measuring technique. Ha (9b)

Testing for Adherence of Galvanized Coatings. B. P. Finkbone. *Journal American Zinc Institute,* Vol. 17, 1936, pages 76-80. In order to show how galvanized sheets will perform in forming operations a proper test should take in the following factors: (1) Severity of forming for a given weight of coating, (2) elongation of material to be expected from the forming to be done, (3) speed of operation, (4) variation in weight of coating. As a supplement to such a test it is very desirable that a standard method of interpretation be established. Such a method could be developed from an examination of numerous test results. It would probably be necessary to base it upon a visual examination of the test samples together with the correlation of certain specific test conditions with those of actual fabricating operations. BHS (9b)

Relationships in Cast-iron Test Results. G. L. Harbach. *Proceedings Institute of British Foundrymen,* Vol. 28, 1934-1935, pages 317-344. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 139L/2. CEJ (9b)

Technical Determination of the Elastic Modulus of Metals at Elevated Temperature by a Creep-limit Device according to Dr. Rohn (Ueber eine technische Bestimmung des Elastizitätsmoduls von Metallen bei erhöhter Temperatur mittels Kriechgrenzengerät nach Dr. Rohn) H. Krainer. *Messtechnik,* Vol. 12, June 1936, pages 111-114. The principle of the method is that the elastic shortening of a specimen under load is offset by thermal expansion by automatically increasing the temperature of the specimen electrically if the load is removed. Theory of the method is derived, and the application illustrated by an example. Ha (9b)

■ 9c. Fatigue Testing ■

H. F. MOORE, SECTION EDITOR

The abstracts appearing under this heading are prepared in cooperation with the A.S.T.M. Research Committee on Fatigue of Metals. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

Rapid Fatigue Test. J. W. Cuthbertson. *Metal Progress,* Vol. 29, June 1936, pages 67, 86. See "The Load-Deflection Fatigue Test," *Metals & Alloys,* Vol. 7, June 1936, page MA 309L/2. WLC (9c)

Effect of Continuous Corrosion and Abrasion on the Fatigue of Steel. T. U. Matthew. *Journal, Royal Technical College,* Vol. 3, Jan. 1936, pages 636-660. Details are given of experiments which were conducted on a Wöhler type fatigue testing machine fitted with specially designed auxiliaries giving a continuous abrasive and corrosive effect while the specimens were running under load. A new type of action is described where continuous abrasion and abrasion with corrosion is applied on the loaded specimens and the results obtained are compared with previous results where "surfacing" had been done previous to loading or where continuous corrosion takes place during the test. Continuous abrasion is found to have a serious crack-forming tendency, whereas continuous polishing is found to act as a crack inhibitor in proportion to the fineness of the polishing effect. Continuous abrasion and corrosion acting simultaneously are shown to have a mutually inhibitive effect, due to the reduction of abrasion to polishing by lubricating action of the corrosive field. A new "short time" method of determining the fatigue limit is also described, and the accuracy of method checked by means of a series of tests on a 3.5% Ni steel. JWD (9c)

Endurance Strength of Cast Iron, Malleable Iron and Cast Steel (Ueber die Dauerfestigkeit von Gusseisen, Temperguss und Stahlguss) R. Mailänder. *Technische Mitteilungen Krupp,* Vol. 4, June 1936, pages 59-66. Results of work in this direction are reviewed, tables are given comparing mechanical properties of the 3 materials and the relation between tensile, bending and oscillating stresses and effect of notches discussed. 26 references. Ha (9c)

Are Fractures of Automobile Rear Axles Fatigue Fractures (Sind Brüche von Kraftwagen-Hinterachswellen Dauerbrüche)? M. Ulrich. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, Feb. 15, 1936, pages 181-182. Investigation of a great number of fractures of grooved axles and shafts showed conclusively that the fractures are not simple fatigue (endurance) fractures but are due to overstresses produced by the shape of the section of the piece, and that fractures in operation are not caused by torsional stresses. Torsional stresses below the elastic limit very likely start the fracture in the corners of grooves where the peaks of the stresses occur. The effect of the structural nature of the material is discussed. Ha (9c)

Strength of Metals under Combined Alternating Stresses. H. J. Gough. *Iron & Steel Industry,* Vol. 9, Jan. 1936, pages 132-137; Feb. 1936, pages 177-178. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 25R/2. CMS (9c)

Investigation on the Effect of an Addition of Cadmium on the Endurance Limit under Reversed Flexure of Copper Wire (Untersuchung über den Einfluss eines Kadmiumzusatzes auf die Schwingungsfestigkeit von Kupferdraht) W. Engelhardt. *Mitteilungen aus dem Forschungsanstalten des GHH-Konzerns,* Vol. 4, May 1936, pages 144-146. Electrolytic Cu wire and Cd-Cu wire, one drawn to the same tensile strength as electrolytic Cu wire and another drawn with higher tensile strength were compared; the Cd addition was 0.43%.

	tensile strength kg./mm.^{2}	endurance limit under reversed flexure for 50 million alternations kg./mm.^{2}
Electrolytic Cu wire	39.0	9.1
Cd-Cu wire	39.6	11.3
Cd-Cu wire	44.4	12.4

Although the electric conductivity is lower, about 51.8 ohm/mm.^{2} against 57 ohms, the static and dynamic properties are improved by the Cd addition in such manner that the reduction in conductivity is more than offset in many practical applications. Ha (9c)

Dependence of Endurance Strength of Steel on the Frequency of the Load Alternations (Abhängigkeit der Wechselfestigkeit des Stahles von der Lastwechselfrequenz) F. Körber & M. Hempel. *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Düsseldorf, Vol. 18, No. 1 1936, pages 15-19. Attention is called to the effect of stress distribution over the section of the specimen when the ratio, endurance strength under alternating load to tensile or bending strength, is determined. Tests on following steels: 11C-.16 Cu; .17C-.48 Cu; .44C-.15 Cu; 0.64C-0.10 Cu; and 3 Cr-Ni steels, showed that the endurance strength for high frequencies (450/sec. in the tests) is from 8-13% higher than for lower frequencies (450/min.) The damping effect of the material is of great influence. Curves show the endurance strength under different conditions. 15 references. Ha (9c)

10. METALLOGRAPHY

J. S. MARSH, SECTION EDITOR

The Allotropy of the Chemical Elements and the Results of X-ray Study (Die Allotropie der chemischen Elemente und die Ergebnisse des Röntgenographie) M. C. Neuburger. Ferdinand Enke Verlag, Stuttgart, 1936. Paper, 6¼ x 9½ inches, 106 pages. Price 9.30 RM.

The first question to be asked about a book of this title is "Why was it written?" In answer, it should be stated that while there are various tables and summaries of the crystal structure of the elements, these do not cover all of the various types of experiments that can indicate a change in crystal structure, nor do they critically discuss the evidence in doubtful cases. While it is true that almost no one believes that Al, Cu, Ag and Pd exist in more than one crystal form, it must be admitted that all of these as well as many other elements have been suspected at one time or another of being allotropic, and that there may be justification for a book that summarizes the evidence for and against allotropy in such cases. Mr. Neuburger's treatment of each element is brief but thorough; determinations of the thermal variation of the physical properties are mentioned and in a sentence or two the anomalies and critical points in these properties are discussed. These are followed by references to the X-ray diffraction studies and the conclusions to be drawn from them: the temperature range of stability of each modification and its lattice constants (the latter as given by Neuburger in "Gitterkonstanten für das Jahr 1936, *Zeitschrift für Kristallographie,* Vol. 93, 1936, pages 1-36). Atomic coordinates are not listed; the structures are illustrated in diagrams and are referred to by the various symbols. According to this listing, which is the most recent and most complete that has appeared, there are 23 elements known to have allotropic modifications (Fe, Co, Ni, Rh, Ru, Mn, Cr, W, U, Zr, C, La, Ce, Be, Ca, Tl, Sn, As, P, N, O, S, Se), and there may be allotropes of some 14 others (probably Hf, Th, Ba, Sr, Pr, Nd, Er, and possibly I, Te, Sb, Bi, Ge, Ag and Pd). The book concludes with short chapters on Wever's classification of the alloys of Fe as to the shape of the γ-field; a brief, uncritical summary of studies on orientation relationships resulting from transformations; and a bibliography that contains 1002 references.

Unfortunately the author has taken no pains to make the book convenient for occasional reference—it leaves the reader wishing the book had been condensed into a table. The elements are not arranged alphabetically nor by atomic number, but in groups that must be located via the index or the table of contents. The bibliography is arranged alphabetically by author's name up to entry 921, but is haphazard from 921 to 1002; it is run together in a most annoying manner, without paragraphing or bold faced numbers or letters to assist the reader in finding a given reference. C. S. Barrett (10) -B-

Note on the Tarnishing of Liquid Metals as Studied by X-rays. Hugh O'Neill & G. S. Farnham. *Journal Institute of Metals,* Vol. 57, No. 2, 1935, pages 253-256. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 144L/9. (10)

Further Study of Copper-tin Alloys by X-ray Analysis. E. A. Owen & E. C. Williams. *Journal Institute of Metals,* Vol. 58, Mar. 1936, pages 153-167 (Advance Copy No. 730). The study concerns δ and η phases. The δ region was examined at temperatures below 550° C. and found to be solid solution. The range of solution increases from zero at the eutectoid point, which is at 67.15% Cu and 330° C., to 0.48% by weight at 550° C. The η phase was found to be solid solution, the range of solution at 250° C. extending from 61.68 to 62.10% and at 530° C. from 61.68 to 62.20% Cu by weight. Observations are also recorded which confirm the conclusion that the δ phase transforms to $(\alpha + \eta)$ at approximately 330° C. 11 references. JLG (10)

Alloys of Platinum with Rhodium (Ueber Legierungen des Platins mit Rhodium) W. A. Nemilow & N. M. Woronow. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 226, Feb. 7, 1936, pages 185-191. See *Metals & Alloys,* Vol. 6, June 1935, page MA 247L/9. WB (10)

X-ray Measurement of the Thermal Expansion of Pure Nickel. E. A. Owen & E. L. Yates. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Vol. 21, Apr. 1936, pages 809-819. The thermal expansion of the crystal lattice of 99.98% Ni was measured over the range from 12° to 600° C. The structure remained face-centered cubic over the whole range; the parameter at 18° C. was found to be 3.5172 A.U. and the density 8.897 g./cc. The maximum value of thermal expansion occurs at 370° C. and is 26×10^{-6}. A considerable irregular change takes place in the region of magnetic transformation. The ferromagnetic change in length per unit length is about 2.4×10^{-4}. An attempt is made to explain generally the occurrence of transformations in alloy systems at certain temperatures by the migration of atoms from point to point in the lattice. Ha (10)

Influence of Various Factors on Graphitization During Solidification of Cast Iron (Influence de divers Facteurs sur la Graphitisation à la Solidification des Fontes) Albert Portevin & Robert Lemoine. *Comptes Rendus,* Vol. 202, Apr. 15, 1936, pages 1343-1345. Studies were made of Ca and Si additions to molten cast Fe and the number of graphite particles/mm.^{2} noted under the microscope. These effects were correlated with the ability of the sample to be chill cast and with changes in physical properties. FHC (10)

Representation of Ternary Systems (Darstellung von Dreistoffsystemen) E. Scheil. *Archiv für das Eisenhüttenwesen,* Vol. 9, May 1936, pages 571-573. To enable the reader to utilize ternary systems more easily a scheme is proposed whereby the transformations in 3 and 4 phase equilibria are indicated by the chemical symbols and arranged in tabular form. Since in ternary ferrous alloys the limits of the austenite and ferrite fields are of especial interest, these limits are projected either onto the base of the solid models or onto one of the sides. SE (10)

A Survey of the Iron-carbon Diagram Near Zero Carbon (Below 1000° C.). J. H. Whiteley. *Iron & Steel Institute,* Advance Copy No. 15, May 1936, 10 pages. A cupric etching method that makes cementite readily apparent in steels containing less than 0.03% C is described. By means of this etching the gradual solution of cementite in α Fe on heating above 550° C. was examined. Results indicated that the solid solubility of C in Fe did not vary between room temperature and 550° C. Above 800° C. the formation of martensite in very low-C steel was observed, thus enabling the location of the line separating the α and $\alpha + \gamma$ field. 12 references.

Plasticity of Metal Crystals and Its Importance for Properties of Materials (Plastizität von Metallkristallen und ihre Bedeutung für die Werkstoffeigenschaften) G. Wassermann. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, Mar. 7, 1936, pages 283-287. In the deformation of metals, 2 crystallographic processes are effected: translation and mechanical twin formation. These processes are investigated for different kinds of crystals and it is shown that the dependence of the elastic modulus on direction, the mechanical strength and other properties can be explained and, in some cases, even calculated from monocrystal data and structural examination of a metal. The application of these theories to practical problems, in particular for working processes of Mg alloys, is illustrated.
Ha (10)

Austenitic Grain-Size in Cast Iron. D. W. Murphy & W. P. Wood. *Transactions American Society for Metals,* Vol. 24, Mar. 1936, pages 75-95. A network developed by heating cast Fe to 1560°-1650° F. shows varying grain size for irons of essentially the same composition but varying ultimate strength. As-cast strength increases with grain size. Study of the hardenability of these irons shows that property to increase with grain size. Further study of this phenomenon is suggested as an aid in control of cast Fe and knowledge of its heat treatment possibilities. In discussion some doubt is expressed as to the reality of the network or cellular structure representing austenite grain size.

Reactions in the Solid State (Reaktionen im festen Zustande) W. Jander. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, Apr. 25, 1936, pages 506-510. Reactions in solid state take place in case hardening of Fe, hardening of Al alloys, ore-roasting processes, manufacture of cement and ceramic products. They are explained in detail and micrographs of the structures at various stages shown.
Ha (10)

On the Preparation of Iron and Steel Specimens for Microscopic Investigations. Francis F. Lucas. *Transactions American Society for Metals,* Vol. 24, Mar. 1936, pages 1-25. Describes methods and materials for preparation of specimens. A flotation apparatus for preparation of abrasives is described and particle size analysis of MgO used is given.
WLC (10)

Theory of Metallic Crystal Aggregates. Charles G. Maier. *Metals Technology,* Apr. 1936, *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 701, 50 pages. Density changes in Cu cold worked by rolling, drawing, or torsion were determined. Similar measurements on ingot Fe were supplemented by coercive-force determinations. Variations of density of Fe were similar in kind to those observed in cold working Cu, including a minimum in density in drawing. It is concluded that metallic crystal aggregates, typical of annealed rolled metals, show density changes that are functional, rather than random, with increasing cold work, but the original density in the annealed state may be somewhat random, as affected by mosaic block structure. Lattice distortion is attributed to the result of changes occurring in deformation. Semi-quantitative explanation of observed behavior requires postulation of the existence in the metal of atoms having higher heat and energy content than the lattice, which have been treated as a new phase differing from the Beilby "amorphous cement" in being a denser adsorbed film, and having little to do with work hardening except to explain the existence at inter-crystalline boundaries of a potential barrier partly permeable at ordinary temperatures to atomic dislocations, thus conforming with and complementing the Taylor dislocation theory of strain hardening. 37 references.

Oxalic Acid as an Electrolytic Etching Reagent for Stainless Steels. George A. Ellinger. *Transactions American Society for Metals,* Vol. 24, Mar. 1936, pages 26-45. Advantages of described method of etching are given as, (1) it reveals both carbides and grain boundaries, (2) it is rapid and not dangerous, (3) specimens do not stain, (4) specimens are suitable for high magnification study and (5) application to welded joints gives good results. Specimen is made the anode, Pt cathode, in 10% water solution of oxalic acid using 6 volts.
WLC (10)

11. PROPERTIES OF METALS AND ALLOYS

Condition of Electrolytically Deposited Metals (Ueber den Zustand elektrolytisch abgeschiedener Metalle). G. Tammann & H. Jaacks. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 227, May 28, 1936, pages 249-260. Grain size of Cu deposit varies, being smaller near cathode surface and increasing toward anode. In contrast with 77% cold drawn Cu which shows visible recrystallization at 250° C. and quite evident at 600° C. the deposited Cu shows grain growth at 300° C. and recrystallization starting at 600° C. Table is given showing progress of grain growth and recrystallization for deposited Cu in 3 zones of the deposit where grains originally are small, intermediate and large and after recrystallization grains are uniformly .2 mm. in size for all 3 zones. Structure and behavior on heating of Fe, Zn and Ni deposits are reviewed. Lattice distortion in electrolytically deposited metals is compared with lattice distortion of hardened state of metals since distortion in both disappears on heating. Cu, Ni, Fe, Zn, Cr in natural deposited state are hard and hardness has been attributed to dissolved H_2 but table shows that it cannot be the cause of hardness when compared with annealed and rolled material and it is noted that with higher bath temperatures Fe is softer than usual. Curve is shown for hardness of Ni and H_2 content versus pH where hardness and H_2 content are directly opposed. Data are cited as furnished by the literature which indicate lack of correspondence between indentation hardness and H_2 content. Solution velocity tests in $3N$ H_2SO_4 were made with electrolytic Fe and Zn after heating from 20°-570° C. (20°-415° C. for Zn) for 1¼ hr. in H_2 atmosphere. It was found that electrolytic Fe at the start dissolves more slowly than re-melted, rolled electrolytic Fe but after 150 minutes of test the corrosion velocity is greater for the electrolytic Fe. Since the H_2 can be removed from the deposited metals by heating under vacuum and no difference in hardness and solution velocity obtained thereby it is considered that the deposited metals are under strain as are metals in hardened state. This is tied up with temperature of deposition and presence or absence of chemical and cooncentration-polarization.
WB (11)

Engineering Alloys (Names, Properties, Uses). N. E. Woldman & A. J. Dornblatt. American Society for Metals, Cleveland, 1936. Cloth, 6 x 9¼ inches, 622 pages. Price $10.00.

This is a sort of "Campbell's List" enlarged to some 8200 entries. It gives the trade names of steels and other alloys, who makes them, and states something as to the properties claimed by the maker and the uses for which he advocates them. It is emphasized that only the maker's statements, uncorroborated and unqualified, are given. If one knows the trade name or the maker's name, the index is so arranged that the entry can be found, but if one wants to find out if an alloy of a given composition is on the market, the index leads to the answer only in the case of heat-resistant and corrosion resistant alloy steels. Unless it is hidden away under some sub-heading in the index, which does not indicate its presence, no cadmium-base bearing alloy is listed, nor can we find reference to the Ford crankshaft alloy. The title might more accurately be "Trade-named" than "Engineering." Nevertheless, there is a surprising lot of information that one sometimes wants, and when he wants it, he always wants it in a hurry. That the information is not complete is only to be expected and one is thankful for what there is. Once in a while the gaps are irritating, as it is often stated that some alloy steel contains "C, Fe and alloy," which means that the maker didn't tell, while in others the maker's information is incompletely quoted, e.g., no P is listed in the Cor-ten analysis, though there are plenty of publications which comment on its presence.

On the whole, the compilation is worthwhile and while its failure to tell the whole story will often irritate the reader, he should be less irritated than by the entire lack of information he would often have to contend with without it.

The price seems high, but such a book is costly to print.

A. J. PHILLIPS, SECTION EDITOR

Copper-Lead Antifriction Alloys (Alliages Antifrictions Cuivre-Plomb). A. Ricard. *Usine,* Vol. 45, Jan. 2, 1936, page 37. The properties of Cu-Sn-Pb alloys are explained on the basis of the Cu corner of the ternary diagram. Tensile strength and resistance to repeated shocks decrease with increasing Pb content from 0.25 to 25% and decreasing Sn content from 10 to 0%. Alloys of Cu-Pb with less than 2.5% Pb are unsuitable for bearings but are used for oil rings, packing rings, pistons and air pumps. 2.5% Pb does not sufficiently improve the friction properties but does improve the machinability. 10% Pb is necessary to obtain the plasticity desired in polishing and peening the bearing surfaces. Sn rich bronzes with 5-8% Sn are less sensitive to high temperatures and therefore suitable for bushings under heavy load. The wear resistance is little modified from 12 to 25% Pb, but the mechanical properties deteriorate beginning from 15% Pb. The Pb alloys can be machined with speeds higher than 100 m./sec.; broaching is a particularly suitable method.
Ha (11a)

Magnesium and its Ultra Light Alloys (La Magnésium et les Alliages Ultra-Légers). Paul Bastien. *La Technique Moderne,* Vol. 27, Feb. 1, 1936, pages 65-71. Discusses the foundry properties of ultra light alloys as to their castability, shrinkage and common defects. The work of W. Schmidt on the hot working of ultra light Mg alloys is summarized. Machining of these alloys is very easy and is made at highest machining speeds with tools having a cutting angle of 12°. The corrosion resistance of Mg base alloys is discussed, those having the best resistance being those containing Mn and Mn + Al. The most common process for their surface treatment consists in immersing the alloys for some hours in alkaline chromate and dichromate mixtures heated to 90° C. Another process is by coating with Se. Metallization by the Schoop process and electroplating have not yet been successful.

GENUINE DETROIT THERMOSTAT

DETROIT LUBRICATOR COMPANY

To maintain the high standard already established by Genuine Detroit products, the Detroit Lubricator Company, uses only Chace Thermostatic Bimetal.

Manufacturers whose products call for unfailing automatic action at predetermined temperatures or whose object it is to hold temperature within a close given range, will find Chace Thermostatic Bimetal a most reliable servant.

Zinc-Indium Alloy System. CURTIS L. WILSON & ETTORE A. PERETTI. *Industrial & Engineering Chemistry,* Vol. 28, Feb. 1936, pages 204-205. Based on the preparation and examination of 30 alloys of Zn and In, the equilibrium diagram was constructed from the combined cooling curves. 4 photomicrographs are shown. The alloys become softer as the In content is increased; the 54% In alloy can be scratched with the finger nail. All of the alloys have a silvery white color. MEH (11a)

Aluminum-copper-nickel Alloys of High Tensile Strength; K. Monel (Cupro-nickels à l'aluminium à haute rèsistance; Monel K). W. A. MUDGE & P. D. MERICA. *Métaux,* Vol. 10, Dec. 1935, pages 336-340. Extracted from two publications: "Aluminum-copper-nickel Alloys of High Tensile Strength subject to Heat Treatment," *Metals Technology,* Apr. 1935 (See *Metals & Alloys,* Vol. 6, Aug. 1935, page MA 333L/4) and "Engineering Properties of K Monel," Bulletin T 9, International Nickel Company. GTM (11a)

Rolling Technique and Properties of Lead Bearing Alpha Brasses. P. I. GRADUSOV. *Tzvetnuie Metallui,* June 1935, pages 58-65. (In Russian). A description of melting, casting, cold rolling technique, and properties of brasses containing 2.1 and 2.6% Pb. BND (11a)

White Bearing Metals with High Tin Content (Hochzinnhaltige Lager-Weissmetalle). FRHR. v. GÖLER & H. PFISTER. *Metallwirtschaft,* Vol. 15, Apr. 10, 1936, pages 342-348; Apr. 17, 1936, pages 365-368. Sn bearing metals containing 3-10% Cu and 2-12% Sb were prepared from high purity materials and their mechanical properties determined. This is supplemented by the information already in the literature. Within the solid solution range from 0-9%, Sb increases the resistance to deformation and the endurance limit, beyond this range it does not improve these properties and causes embrittlement. Cu has the same effect to a smaller extent. Of the common impurities Pb is the most objectionable due to its eutectic with Sn and Sb melting at 180°. Ni and Cd have some value as hardening additions. The change in mechanical properties with temperature is about the same for all alloys of this type. GD (11a)

Plasticity of Bismuth Crystals. H. J. GOUGH & H. L. COX. *Nature,* Vol. 137, Apr. 25, 1936, page 701. Alternating torsional stresses having previously failed to produce slip in Bi crystals, reversed direct stress (tension and compression) was tried on a single crystal. Again slip lines were absent (except near the fracture) and deformation was by twinning. However, when the same crystal was subjected to static compression along the same axis, it deformed by slip rather than by twinning. CSB (11a)

Working of Lead (Le travail du Plomb) J. MAHUL. *Métaux,* Vol. 10, Dec. 1935, pages 371-390. Working, welding and uses of Pb are generally discussed. GTM (11a)

Working of Monel Metal (Le travail du metal Monel) J. PICARD. *Métaux,* Vol. 10, Dec. 1935, pages 324-335. Welding, fabricating, cleaning and general treatments are discussed. GTM (11a)

Low Alloy, High Yield Strength Structural Steel. An Extended Abstract. *Metals & Alloys,* Vol. 7, Mar. 1936, pages 77-84. Discusses findings of recent papers on high yield strength structural steels and their applications. Properties and compositions are tabulated for 32 steels in this classification. 5 references. WLC (11b)

The Lincoln-Zephyr Cast Alloy Pistons. Edwin F. Cone. *Metals & Alloys,* Vol. 7, Apr. 1936, pages 85-87. Electric furnace melted alloy steel castings used for piston castings in Lincoln-Zephyr have the following composition: C 1.35-1.70, Mn 0.60-1.00, Si 0.90-1.30, S 0.08 max., P 0.10 max., Cu 2.50-3.00, Cr 0.15-0.20. Castings are normalized from 1650° F., drawn from 1400° F. and show elastic limit 70,000 lbs./in.^{2}, tensile strength 90,000 lbs./in.^{2} elongation 5.0% in 2 in. and Brinell 207-241. WLC (11b)

Deep Drawing Properties of Harder Carbon Steel Sheet (Tiefziehfähigkeit von härteren unlegierten Stahlblechen) F. Eisenkolb. *Archiv für das Eisenhüttenwesen,* Vol. 9, May 1936, pages 575-578. From Erichsen and tensile tests of C steel annealed sheet, 1 mm. thick, relationships were drawn between tensile strength, elongation, and Erichsen values. The drawability decreased with the hardness. Sheets of tensile strength up to 80 kg./mm.^{2} still showed good drawability. SE (11b)

A Study of the Influence of Varying Degrees of Cold-rolling and Annealing Temperatures on the Properties of Mild Steel Sheets. Part I.—The Influence of Cold-rolling and Subsequent Annealing Temperatures on the Erichsen Values and Crystal Structure of Thin Mild Steel Sheets. C. A. Edwards, D. L. Phillips & W. H. E. Gullick. **Part II.—The Effects of Varying Degrees of Cold Rolling and Annealing Temperatures on the Properties of Motor-car Body Sheets.** C. A. Edwards, D. L. Phillips & C. R. Pipe. *Iron & Steel Institute,* Advance Copy No. 6, May 1936, 67 pages. For work described in Part I two classes of tin-plate steel were used, one relatively low in P and S and the other relatively high. For each steel one set of experiments was made on sheet that had been annealed below 900° C. prior to cold rolling, and the other on which the preliminary annealing temperature was above 950° C. In this way it was possible to examine the effects of chemical composition and initial grain size on the critical degree of cold rolling that produces coarse crystallization on subsequent annealing. With heavy cold rolling complete recrystallization occurred on annealing at temperatures as low as 750° C. irrespective of the original grain size. Under such conditions of heavy cold rolling and low-temperature annealing better Erichsen values were produced than by present-day commercial methods, which consist in hot rolling almost to the final gage and annealing in batches at temperatures below 900° C. Part II is an extension of the work done in Part I to determine the influence of cold rolling and annealing on the tensile properties, hardness and Erichsen values of mild steel sheets used in motor-car construction. This represents a preliminary attempt to correlate the effects of cold rolling and annealing, the tensile properties, and crystal structure with the Erichsen values, and further to ascertain whether the tensile properties obtained after heavy cold rolling and low-temperature annealing approach those obtained by full annealing. The evidence seems to indicate clearly that, when complete recrystallization occurs with low-temperature annealing after heavy cold rolling, the tensile properties show that the drawing qualities should be about the same as those obtained by annealing at, say, 950° C. It was not possible to prove by actual drawing operations that this was the case. JLG (11b)

Small Plastic Deformations in Strip Steel. Directional Properties, Caused by These, Detected by X-Ray Diffraction. Norman P. Goss. *Metals & Alloys,* Vol. 7, May 1936, pages 131-134. Study of slight plastic deformation, 0-15%, showing that the preferred orientation developed by such deformation can be detected. Hot rolling develops preferred orientation which must be allowed for in subsequent cold work. Small degrees of cold work on heat treated metals only fragment the crystals. Preferred orientation is developed in different directions in hot and cold worked wires. WLC (11b)

Chromium and Manganese in Structural and Stainless. Augustus B. Kinzel. *Metal Progress,* Vol. 29, Mar. 1936, pages 46-51, 74. Low Cr-Mn steels have relatively high ductility with increasing tensile strength up to 100,000 lbs/in.^{2} but beyond this point the ductility-strength ratio falls off sharply and the composition is said to be "unbalanced." In sections up to 1.25" and range of strength 70-95,000 lbs./in.^{2} with C 0.10-0.20% steels of 1.25% Mn, 0.5% Cr, and 1.0% Cr, 0.50% Mn are balanced in normalized condition. In a rolled state both are unbalanced but use of 0.75% Si balances the compositions. Discusses the properties of 18 Cr-8 Mn steels as being less susceptible to intergranular corrosion after welding than 18-8 Cr-Ni steel. This composition is about 60% austenitic and 40% ferritic giving the advantages of formability and easy machining of these two constituents. WLC (11b)

Phosphorus as an Alloying Element in Low Carbon, Low Alloy Steels. C. H. Lorig & D. E. Krause. *Metals & Alloys,* Vol. 7, Jan. 1936, pages 9-13; Feb. 1936, pages 51-56; Mar. 1936, pages 69-73. Study is reported of static and impact properties of steels C 0.06%-0.26%, P up to 0.6% with Al treatment for fine grain, with additions of M, Cr, Zr, V, Ti, Ni, Cu and Si singly. Results show satisfactory static ductility even above 0.3% P but at that point impact brittleness is impaired. C and Si additions favor brittleness, Cr definitely and Ni, Cu and Mo less definitely tend toward impact toughness in P steels. In Al treated steel effect of Ti or Zr may be helpful but not so markedly as Cr. Resistance to atmospheric corrosion is improved with P above usual limits in plain P, Ni-P and Cu-P steels. 7 references. WLC (11b)

High-Quality Steels. H. H. Burton. *Times* [*London*] *Trade & Engineering,* Vol. 38, Apr. 1936, pages VI. IX. Outlines development of steel-making processes; melting processes used for making alloy steels; composition and applications of some of the alloy steels made in Sheffield, England; heat treatment; and metallurgical control. MS (11b)

12. EFFECT OF TEMPERATURE ON METALS AND ALLOYS

L. JORDAN, SECTION EDITOR

The abstracts in this section are prepared in co-operation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

The Behaviour of Five Cast Irons in Relation to Creep and Growth at Elevated Temperatures. H. J. Tapsell, M. L. Becker & C. G. Conway. *Iron & Steel Institute,* Advance Copy No. 14, May 1936, 27 pages. Creep and growth characteristics of ordinary cast Fe, Ni-Cr Fe, Silal, Nicrosilal, and Niresist were studied between 700° and 1000° F. Effects of prolonged heating on microstructures were also studied. A few comparative creep and growth tests were made on Silal, Nicrosilal and Niresist at 850° C. Creep and growth characteristics of austenitic Nicrosilal at 840° F. and 1000° F. are very little different from ordinary Fe in the as-cast condition. The poor properties of this Fe are probably due to instability of austenite at these temperatures. Good resistance to creep and growth at the 2 temperatures was shown by Niresist, which is also austenitic. It possessed better resistance to growth at 1000° F. than at 840° F. At 850° C. Nicrosilal was superior to both Silal and Niresist. Heating below critical temperature improved growth properties of ordinary and Ni-Cr Fe. JLG (12)

Properties of Rail Steel at Arctic Temperatures. H. B. Wishart & W. D. Boone. *Metal Progress,* Vol. 29, Jan. 1936, pages 61-62. Graphical presentation of data on tensile strength, Brinell hardness, fatigue limit (notched and unnotched), reduction of area, elongation and unnotched Izod of rail steel for the temperature range — 40° to + 80° F. Decreased strength and toughness accompany lower temperatures. WLC (12)

13. CORROSION AND WEAR

V. V. KENDALL, SECTION EDITOR

Protection of Underground Oil Pipe-Lines. *Synthetic & Applied Finishes,* Vol. 6, Feb. 1936, page 274. A discussion of methods for anti-corrosive protection of pipe-lines in the Russian oil fields is presented. The efficiency of the various methods are reported to have been tested by exposure to H_2SO_4, HCl, NH_3, NaOH, NaCl, H_2SO_3, H_3PO_4, fresh water and sea-water. Efficient protection was achieved not only with bitumen paints but with wrapping materials previously impregnated with bitumen. 4 feasible processes for applying the protective coatings to the tubes were developed: (1) Steel tubes are cleansed, immersed inside and out in primer, dried, brushed with bitumen solution thickened with talc, dried, treated with third coat, dried and patched. (2) Tubes are primed, coated once with varnish, wrapped in wax paper and treated with third coat. (3) Pipes are primed inside and out then bunged at the ends, treated on the job externally with thickened bitumen, cooled, treated with unthickened bitumen, wrapped with wax paper and brushed with cold bitumen. Pits are filled with china clay. (4) For salt water exposure pipes are treated as in (3) except that bitumen is thickened with cement instead of talc, and wax paper is replaced with bitumen-impregnated cloth. FPP (13)

The Scaling of Mild Steel in Sulphur-free and Sulphur-containing Furnace Atmospheres. Institution Gas Research Fellowship Report: 1934-35. H. C. Millett & John W. Cobb. *Institution of Gas Engineers, Communication* No. 127, 73 pages; *Gas World,* Vol. 103, Nov. 16, 1935, Industrial Gas Supplement, pages 7-10; Dec. 1935, page 543; *Gas Journal,* Vol. 212, Nov. 13, 1935, pages 503-505; Dec. 4, 1935, page 695; *Engineering,* Vol. 140, Nov. 22, 1935, pages 567-568. Scaling in N was negligible, was evident in CO_2, and definitely more pronounced in steam. Scaling in an atmosphere analyzing steam 2%, CO_2 18% and N 80%, representing the products of combustion of dry, high-temperature coke, was 0.0043 g./cm.^{2} when exposed 1 hour at 1000°. In CO_2 10%, steam 10%, and N 80%, representing combustion gases from coal, producer gas or fuel oil, scaling was twice as great. To render the above nonscaling required 29% H, 95% CO or 21% CH_4. Products from coal gas gave 0.0120 g. scale/cm.^{2} C particles had no appreciable anti-scaling value. Addition of O increased scaling; 2% O_2 added to above, increased scaling 8 times. Increase of O increased scaling up to a certain point, beyond which further increases had no effect; this concentration increases with temperature. At 1000°, 0.1% SO_2 in a neutral furnace atmosphere gave the same increase in scaling as 1% free O_2. When O_2 was 2½-3% the influence of added SO_2 was lost. Oxides of N had little effect. There is a certain critical furnace gas velocity below which the scaling decreases rapidly with the gas velocity. Scaling increases rapidly with temperature. As the period of exposure is increased, scaling increases but at a rapidly diminishing rate. Increasing temperatures produce increasing scaling. LFM + AHE (13)

Corrosion Below Discontinuous Oxide Coatings, with Special Reference to Magnesium. K. G. Lewis & U. R. Evans. *Journal Institute of Metals,* Vol. 57, No. 2, 1935, pages 231-252. Includes discussion. See *Metals & Alloys,* Vol. 6, Oct. 1935, page MA 417L/4. (13)

Organic Inhibitors of Corrosion—Aliphatic Amines. Charles A. Mann, Byron E. Lauer & Clifford T. Hultin. *Industrial & Engineering Chemistry,* Vol. 28, Feb. 1936, pages 159-163. The blanketing or protective layer of the aliphatic amines is formed by adsorption of inhibitor ions on the metal surface and through the N atom. Long straight-chain aliphatic diamines and triamines are excellent acid-corrosion inhibitors. Stereochemical structure of these compounds determines their effectiveness as corrosion inhibitors. The longer the hydrocarbon chains and the greater the number up to 3 attached to the N atom, the greater is the effectiveness of the inhibitor and the less inhibitor required. 32 references. MEH (13)

Some Recent Investigations on the Corrosion of Tin. D. J. Macnaughtan & E. S. Hedges. *International Tin Research & Development Council, Technical Publication,* Series A, No. 34, 1936, 13 pages. Sn assumes a thin oxide film in air, but the film is not protective. Oxygen favors solution of Sn in Na_2CO_3 or NaOH solutions; without O_2, corrosion is practically nil. The oxides of Sn are soluble in both acids and alkalis. Differential aeration and hydrogen depolarization are therefore important. In many food stuffs, Sn is anodic to Fe. This occurs when the dissolved Sn forms stable complexes with the solvent, after the oxide film has dissolved. The base steel in Sn plate has an effect on the rate of reversal of the potential of the couple, from initial cathodicity of the Sn to its final anodicity. Some steels corrode faster than others. Cracks in the alloy layer, and pores in the Sn coating of course favor corrosion. References are given to 11 original papers on which this summary is based. HWG (13)

Cylinder Wear, Where and Why. S. W. Sparrow & T. A. Scherger. *S. A. E. Journal,* Vol. 38, Apr. 1936, pages 117-125. Wear is greatest where lubrication is at minimum coupled with high temperature and dirt. Numerous graphs are shown of wear of cylinder versus distance from top of cylinder bore which indicate zone of greatest wear for a variety of conditions. WB (13)

Cylinder Wear in Diesel Engines. G. D. Voerlage & B. J. J. Gravesteyn. *S. A. E. Journal,* Vol. 38, May 1936, pages 197-199. Wear is determined by ash content of oil dripping from cylinder in test operation. Necessity for clean air for engine operation is shown in test when .005% quartz dust added gave wear increase of 600%. WB (13)

Oxidation of Aluminum and Its Alloys by Gases and Liquids. V. S. Zorin. *Legkie Metallui,* Vol. 4, Oct. 1935, pages 12-21. In Russian. Heating Al alloys in air at 550° C. slightly increases their resistance to corrosion. HWR (13)

Cylinder Wear in Gasoline Engines. C. G. Williams. *S. A. E. Journal,* Vol. 38, May 1936, pages 191-196. Attention is called to corrosion-wear when running cold due to condensation of moisture in combustion products on cylinder wall. WB (13)

Anionic Iron (Ueber anionisches Eisen) R. Scholder. *Angewandte Chemie,* Vol. 49, Apr. 18, 1936, pages 255-259. The chemical and electrochemical behavior of Fe and in particular the processes taking place in corrosion of Fe are briefly explained and new tests described to elucidate the nature of passive (anionic) Fe. The corrosion of Fe in strong lyes and its dissolution in hot, strong lyes is due to the base potential of Fe and formation of complex Fe^{II}-hydroxyanions. The production of ferrates and ferrites from the latter is described. By oxidation of ferrate solutions well crystallized, colorless hydroxyferrites could be produced. 23 references. Ha (13)

Wear of Gray Cast Iron as Dependent on Cooling Conditions (El degaste de la fundicion gris a traves de las condiciones de enfriamiento) J. Navarro Alcacer. *Anales de la Sociedad Espanola de Fisica y Quimica,* Vol. 34, Mar. 1936, pages 383-392. The purpose of this investigation was to determine the resistance to wear by sliding of common gray cast Fe. By changing only the rate of cooling, different structures were obtained containing varying amounts of graphite. An Amsler machine was used to test the wear. The resistance to wear does not depend on the amount of graphite present. The optimum resistance was obtained when the graphite appeared as long and uniform lamellae. The author has determined qualitatively the average length of these lamellae. FRM (13)

Metallic Wear. H. W. Brownsdon. *Engineer,* Vol. 161, Mar. 20, 1936, pages 321-322; *Engineering,* Vol. 141, Mar. 20, 1936, pages 310-312. Abstract of paper read before the Institute of Metals. See *Metals & Alloys,* Vol. 7, May 1936, page MA 263L/3. VSP (13)

Soviet-Russian Research in the Field of Corrosion and Prevention of Corrosion (Die sovjetrussischen Forschungsarbeiten auf dem Gebiete der Korrosion und Korrosionsverhütung) M. v. Pohl. *Korrosion & Metallschutz,* Vol. 12, Apr. 1936, pages 89-94. The work done and started during 1930-1935 is reviewed and enumerated by titles, and a list of 104 publications added. Ha (13)

Effect of Concentrated Sodium Hydroxide on Boiler Steel Under Tension. A. S. Perry. *Transactions American Society of Mechanical Engineers,* Vol. 58, Apr. 1936, pages 211-216. The results of a study are reported to develop failures in boiler plates under tension and in contact with high concentrations of NaOH causing caustic embrittlement. It could be concluded that whereas the stresses in the fabricated unit and the concentration of caustic in solution may be primary causes of caustic embrittlement, other factors contributing to metal stress may also have an important share, in particular riveting pressures and purity and uniformity of rivet and plate metal. The presence of both intercrystalline and transcrystalline cracks was established but the former are not always necessarily associated with caustic attack. Ha (13)

Experiments on the Erosion of Materials by Cavitation (Versuche über die Werkstoffanfressung durch Kavitation) H. Schröter. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, Apr. 18, 1936, pages 479-480. The experiments were made on large hydraulic turbines and showed clearly that mechanical impact in the cavitation process can destroy even very hard metals in a short time. The surface quality and velocity of the water are of determining effect. Addition of Al to bronzes produces a highly resistant material which is equal to the best alloy steels. Ha (13)

Influence of Nitrogen on the Wear-Corrosion and Fatigue Fracture of Gliding Steel Parts (Mitwirkung des Luftstickstoffs beim Fressen aufeinander gleitender Stahlteile und beim Dauerbruch) H. Schottky & H. Hiltenkamp. *Stahl und Eisen,* Vol. 56, Apr. 9, 1936, pages 444-446. Severe local friction of steel parts which cause corrosion results in surface nitrogenization of the steel, as can be shown metallographically and chemically. The nitrogenization tends to increase the embrittlement of the cold worked surface, starting cracks which lead to fatigue fracture. SE (13)

Composition and Use of Lead-Base Bearing Metals (Herstellung und Verwendung von Bleilagermetallen) R. Schmidt. *Stahl und Eisen,* Vol. 56, Feb. 20, 1936, pages 228-231. The properties of commercial Pb bearing metals and the results of hardening Pb with alkali and alkaline earth metals are discussed. "Union" bearing metal with 98% Pb, 1.5% Mg, and 0.2% Ca is described. SE (13)

Determination of the Oxidation Losses in Rolling Mill Furnaces. Part II (Versuche über den Abbrand in Walzwerksöfen (II Teil)) F. Strähuber. *Stahl und Eisen,* Vol. 56, Jan. 30, 1936, pages 108-113. The type of surface seemed to have little effect; as cast and turned ingots gave the same oxidation losses. More oxidation occurred in highly oxidizing than in reducing atmospheres; doubling the time in furnace increased the oxidation losses 1.4 times; raising the temperature from 1300° to 1400° C. increased the losses 1.7 times. SE (13)

Corrosion of Precipitation-hardening Aluminum and Magnesium Alloys (Die Korrosion aushärtbarer Aluminium- und Magnesiumlegierungen) E. Söhnchen. *Korrosion und Metallschutz,* Vol. 12, Mar. 1936, pages 41-46. Numerous investigations of the relations between heat treatment and corrosion show that in the precipitation range, corrosion can be less, equal to, or stronger than in the quenched, homogenized state and curves are given for Al, Mg and Mg-Mn alloys. The application to technical improvements in corrosion resistance by heat treatment is described. 11 references. Ha (13)

Sheath Corrosion at Bond Straps Prevented. Edgar F. Wolf. *Electrical World,* Vol. 106, Feb. 29, 1936, pages 37-38, 85. Presence of alkaline moisture in cement fireproofing forms a short-circuited cell when Cu bonds are soldered to the Pb cable sheath and the Pb may be destroyed. Keeping the bond strap out of contact with the fireproofing and providing an insulating coating for the Pb of primary cables are preventive measures which have been found effective in laboratories and in practice. The use of certain types of fireproofing instead of Portland cement gives a slower rate of corrosion. CBJ (13)

Corrosion of Metallic Materials in the Operation of Water Works (Korrosion der metallischen Werkstoffe im Betriebe der Wasserwerke) G. Wiegand. *Werkstoffe & Korrosion,* Vol. 11, Apr. 25, 1936, pages 20-21. Metallic materials and the attacks they are subjected to are discussed and exemplified by data in the operation of the municipal water works of Berlin. Conduits for the pure water are usually of cast Fe or steel, water meters of brass, filtering devices of Cu, earthenware or glass. Cu used in aeration and de-ironing plants was soon transformed into cupric sulphide; a coat of bitumen is applied to prevent it or, better, Al is used instead of Cu. Phosphor bronze in filtration plants instead of Cu stops corrosion losses. Corrosion in pipe lines is due to chemical effects of the soil or stray currents of electric systems. Bitumen paints largely eliminate corrosion on these lines. Sometimes incrustations occur on the inner wall of pipes which can reduce the flow of water considerably. This is removed by scraping. Ha (13)

Corrosion in the Soil of Cast Iron Water Pipes (Bodenkorrosion Gusseiserner Wasserleitungen) C. M. Wichers. *Korrosion & Metallschutz,* Vol. 12, Apr. 1936, pages 81-85. Graphitization of cast Fe pipes occurs very frequently and leads to fracture. Thorough investigation of the conditions of the soil surrounding the pipes showed the importance of the pH value, porosity, presence of sulphates and carbonates. A certain type of bacteria reduces sulphates to H_2S which is dangerous to cast Fe as it forms Fe sulphide and leaves C behind. A surrounding of dense, alkaline reacting material is the best protection, a mixture of loam or clay with addition of lime being recommended. Ha (13)

Corrosion of Tin and Tinned Materials with the Formation of Black Spots (Ueber die Korrosion von Zinn und Verzinnten Materialien unter Bildung schwarzer Flecken) S. Brennert. *Korrosion & Metallschutz,* Vol. 12, Mar. 1936, pages 46-49. See "Black Spots on Tin and Tinned Ware," *Metals & Alloys,* Vol. 6, Dec. 1935, page MA 512R/2. Ha (13)

Electric Pipe-line Drainage. G. I. Rhodes. *Electric Journal,* Vol. 33, Feb. 1936, pages 91-96. Elements of cathodic protection are reviewed. An 80-mile commercial installation is described together with a cost analysis and a discussion of results obtained. See also *Metals & Alloys,* Vol. 7, May 1936, page MA 261R/5. CBJ (13)

Corrosion of Iron and Steel. R. Hadfield & S. A. Main. *Iron & Coal Trades Review,* Vol. 132, Apr. 10, 1936, pages 671-672; Apr. 24, 1936, page 754; *Engineering,* Vol. 146, Apr. 17, 1936, pages 439-440. The work done and results and conclusions reached since 1922 are reviewed. The utility of testing by simulating practical conditions is discussed. Electrolytic action depends on metallic factors and environmental factors, i.e. state of strain, crystal structure, hydrogen over-potential, chemical reactivity and temperature, supply of O, concentration of H, and electrical conductivity of the solution. The stages of corrosion and formation of protective oxide films depending on these factors are discussed individually. Ha + VSP (13)

Photo-electric Activity of Iron and Its Oxides. James S. Hunter. *Nature,* Vol. 137, Mar. 14, 1936, page 460. Measurements of the photo-electric sensitivity, in light of different wave lengths, of surfaces of Fe, Fe_2O_3, and FeO, support theory of gas adsorption rather than instantaneous oxidation as being the initial change undergone by a clean metal surface exposed to the air. CSB (13)

Metals and Alloys in Acid Mine Water. *Mining Congress Journal,* Vol. 22, May 1936, page 92. First use of high Cr-Fe alloys in the coal mining fields was in 1922. Alloys with up to 30% Cr were used. The first difficulties encountered were eliminated as proper casting technique was developed. Now many successful installations of these alloys are found in both the anthracite and the bituminous fields. Many mines report Cr-Fe castings which show no appreciable evidence of corrosion after 7-10 years of service. Alloys with 27-30% Cr have been found satisfactory, while 12-14% Cr and 16-18% Cr do not stand up. Lately Ni has been added, and this has eliminated many foundry difficulties. Recently it has been found that small additions of N greatly increase the strength of Cr castings and refine their grain, but no definite data have yet been obtained in regard to the effect of this element on the corrosion resistance. BHS (13)

Chemical Behavior of Bearing White Metals (Beitrag zur Frage des chemischen Verhaltens der Lager-Weissmetalle) Report of Committee for Non-ferrous Metals. *Korrosion & Metallschutz,* Vol. 12, Mar. 1936, pages 50-52. Investigations had object of determining the catalytic effect of different metals on transformer oil heated in the absence of air. It was found that a 70 hr. heating to 120° C. in presence of Pb, Zn and Sn does not change the oil. The dissolving power of oils for bearing metals was further investigated; the results are shown in curves, pure Pb showing the least loss of weight. Atmospheric influences are very strong, some bearings being entirely destroyed after 2 years storage. 8 references. Ha (13)

Deterioration of Structures in Sea Water. *Engineer,* Vol. 161, Apr. 10, 1936, pages 394-395. Abstract of the 15th report of the Committee of the Institution of Civil Engineers, known as Sea action committee. Parts 2 and 3 are concerned with the corrosion and protection of Fe and steel. VSP (13)

Standardization in the Realm of Corrosion (Normungsarbeiten auf dem Gebiete der korrosion) *Chemische Fabrik,* Vol. 9, Apr. 17, 1936, pages 178-181. Detailed reports containing "tentative specifications" of units of measure, and methods and equipment to be used in corrosion research are submitted by committees of the Deutsche Gesellschaft für chemisches Apparatewesen. FPP (13)

Condenser Performance. V. Walker. *Electrical Review,* Vol. 118, May 15, 1936, page 710. To inhibit fouling of tubes where slime and algae are encountered, circulating H_2O is chlorinated. Tests carried out on Admiralty brass tubes with chlorinated and unchlorinated sea-H_2O indicated that chlorination caused twice as much loss of weight of tube material. Rate of loss due to chlorination decreased continuously. Local dezincification is not as harmful as general dezincification. When upper row of tubes are frequently empty, the resulting high temperatures aggravate tendency towards dezincification. Circulating H_2O containing H_2S is particularly bad for Cu or brass condensers. In some cases inlet ends of tubes are coated with cement paint or "bitumastic" solution to prevent corrosion. Many alloys, such as Cu-Ni, are superior to Admiralty and brass alloys for condenser tubes. Al brass withstands impingement attacks. MS (13)

Deterioration of Structures in Sea Water. 15th Report of the Committee of the Institution of Civil Engineers. Edited by S. M. Dixon & H. J. Grose. His Majesty's Stationery Office, London, 1935. Cloth, 6 x 9¼ inches, 137 pages. Price 12s. 6d.

Connected account written by J. N. Friend of experiments continued for 10 to 15 years on atmospheric and sea water (complete immersion and half-tide) at Aukland, N.Z., Colombo, Halifax, N.S. and Plymouth, together with fresh water immersion at Plymouth on wrought and ingot irons, low, medium and 0.40% C steels, mild steel with 0.6 and 2.2% Cu, 13½% Cr steel, 3-¾% Ni and 36% Ni steel, and hot blast and cold blast cast iron. The 36% Ni steel was superior under all conditions, behavior of the others varied with conditions. Wrought Fe was better than steel in sea water, equal in fresh, inferior in the air. Cast Fe was very good in air. C content did not greatly affect the performance of the steels. The Cu steels showed benefit from Cu in air and fresh water. The Cr steel was good in air and fresh water but pitted badly in sea water. 3-¾% Ni in a .31% C steel helped in air and fresh water, not in sea water. Mill scale was always bad. Full tables and many photos are given. Mild steel painted plates, were exposed at Southampton and Weston-super-Mare for shorter periods. Fe oxide, red and white Pb paints and some of these with a Pb chromate primer, tar and galvanized coatings were used. Mill scale was bad. The Pb chromate primer helped, but tar behaved better than paint. Tar, followed by shellac, followed by paint, was very successful. Full tables are given. Something over half the book is devoted to bare or painted Fe and steel. Other chapters deal with similar tests on timber and concrete. H. W. Gillett (13)—B—

The Corrosion of Metals—I. Mechanism of Corrosion Processes. R. M. Burns. *Bell System Technical Journal,* Vol. 15, Jan. 1936, pages 20-38. Metallic corrosion consists either of a direct combination of the metal with a non-metal in its environment or a combination in which H is displaced from the medium at the surface. This latter or displacement type is involved in the corrosion of metals in moist air, soil, and water, and is electrolytic in nature since it depends on the operation of small surface galvanic elements. The amount of corrosion will depend on the flow of current between these anodic and cathodic areas. The purpose of this paper is to present a generalized electrochemical theory of corrosion of the displacement type. From this it is evident that a knowledge of the anodic and cathodic current density and potential relationships existing on the surface of a metal in a given environment would lead to an understanding of the corrosion process and to predictability of corrosion behavior. While it is not possible to measure these quantities directly because the sizes of these areas are unknown, the potential-time curve is a composite of the resultant potentials and their change with time. It will indicate if the process is anodically or cathodically controlled and in some cases even determine the rate. Furthermore it is possible to determine a measure of the stability of the protective film in terms of the leakage current which may be passed through the film, or in terms of the amount of film-forming material required to produce passivity or in terms of the amount of film destroying material required to render the metal active. The rate at which a film forms on a metal also gives information on the relative surface reactivity of the metal. With the aid of such measurements and an exact knowledge of the metal and its environmental conditions it is possible to predict corrosion behavior and gain an understanding of such processes not given by the usual empirical tests. Effect of Impurities on Corrosion Resistance of Solder. Clifford L. Barber. *Industrial & Engineering Chemistry,* Vol. 28, May 1936, pages 530-533. Tests indicate that Sb, Cu, and Zn should be excluded from Sn alloys from the corrosion-resistance standpoint, because they decrease corrosion resistance. MEH (13)

The Influence of Light on Electrode Potential and Corrosion Phenomena of Certain Non-ferrous Metals. C. O. Bannister & R. Rigby. *Engineering,* Vol. 141, Mar. 20, 1936, page 321. See *Metals & Alloys,* Vol. 7, June 1936, page MA 316R/6. VSP (13)

The Abrasion of Chain Wheels. C. C. Downie. *Crushing, Grinding, Mining & Quarrying Journal,* Vol. 3, Jan.-Feb. 1936, pages 196, 198. Heat-treated C steel, Ni-, Ni-Cr-, and Mn-steels and Ni- and Cr-cast Fe are used to resist abrasion. AHE (13)

Corrosion of Copper—Controlling Factors in Unaërated Solutions of Sulfuric Acid. Glenn H. Damon & Ray C. Cross. *Industrial & Engineering Chemistry,* Vol. 28, Feb. 1936, pages 231-233. Experiments show that the corrosion rate of Cu in H_2SO_4 is directly proportional to O solubility in the acid up to about 25 normal acid; above this concentration the oxidizing character of H_2SO_4 affects the corrosion rate. The maximum corrosion rate for Cu in unaërated 0.2 normal acid is about 40 mg./dm.^{2}/24 hrs. It is suggested that standard corrosion test methods should specify the solution surface area if reproducible results are to be obtained, and that the same factors should control the corrosion rate for all metals which depend upon O depolarization. A subsequent paper will report on some of the more active metals. MEH (13)

Drop Test (L'essai par les gouttes) U. R. Evans. *Revue de Métallurgie,* Vol. 33, Apr. 1936, pages 217-220. Brief summation of the results previously published. JDG (13)

Microchemical Analytical Methods Applied to Corrosion of Light Al Alloys (Sur l'Application des Méthodes d'Analyses Microchimiques à l'Étude de la Corrosion des Alliages Légers d'Aluminium) Henri Fournier. *Comptes Rendus,* Vol. 202, May 25, 1936, pages 1792-1794. Alloys used were (1) duralumin type containing 3.8% Cu, 0.41% Fe, 0.35% Si, 0.46% Mn and 0.91% Mg and (2) Al-Mg alloy containing 0.32% Si, 0.54% Mn and 8.65% Mg. Samples were immersed in a 10% NaCl solution so that the quantity of liquid is small compared to the surface of the sample exposed to the corroding medium. The dissolved products are analyzed by microchemical methods and curves are drawn to show the variation in concentration of the solution as a function of the time. FHC (13)

Oxide Films of Some Alloys. Ichirô Iitaka & Shizuo Miyake. *Nature,* Vol. 137, Mar. 14, 1936, page 457. Electron diffraction patterns indicate that the resistance to high temperature oxidation is due in Cu-Be alloys to a surface film of BeO (hexagonal, $a_o = 2.70$ A.U., $C_o = 4.39$ A.U.) which appears in alloys containing over 1% Be, and in Nichrome to a surface film of $NiCr_2O_4$ or $NiO.Cr_2O_3$ (cubic, $a_o = 8.30$ A.U.). G. L. CRAIG, SECTION EDITOR

Metal Sprayed on Wood. *Engineering,* Vol. 141, Apr. 3, 1936, page 381. Discusses the process of metal spraying, using wire melted by blow-pipe and deposited on wood. Results showed that metals of low melting point, such as Sn, Pb and Zn sprayed on wood, reduced its susceptibility to changes in moisture content and dimensions due to variations in humidity of atmosphere by from 1/4 to 1/3. Metals melting at high temperatures, like bronze, brass, Cu and Al, do not protect wood. Sprayed metal does not protect wood against absorption of H_2O during soaking. VSP (14a)

Tungsten Alloys and Compounds. *Chemical Trade Journal & Chemical Engineer,* Vol. 98, Feb. 21, 1936, page 148. See "The Commercial Development of Tungsten," *Metals & Alloys,* Vol. 7, June 1936, page MA 319L/8. MS (14a)

American Standard Brass Fittings for Flared Copper Tubes for Maximum Cold Water Service Pressure of 175 Lb. per Sq. In. (Gage). *American Standards Association,* A. S. A. No.: A 40.2-1936, 5 pages. AHE (14a)

Copper Alloys to Meet Severe Requirements. D. K. Crampton. *Metal Progress,* Vol. 29, May 1936, pages 39-43, 100. Trend toward use of thinner stock and more complicated designs in deep drawn articles of brass are discussed. Problems of finish, more severe drawing and less frequent annealing are discussed. Pb and Fe must be held below 0.05% for good deep drawing quality though where machining after drawing is to be employed more Pb may be tolerated. Where no final annealing operation is applied and season cracking may be a hazard, alloys containing over 80% Cu should be used. 85-95% Cu alloys are more workable than lower Cu compositions. Where brazing is to be employed at least 72-75% Cu must be used to give sufficiently high m.p. Si bronze for evaporator unit has good workability and weldability with smooth surface and high strength. WLC (14a)

Stainless Steel Proving Serviceable in Variety of Dairy Equipment. *Steel,* Vol. 98, Jan. 13, 1936, pages 34-35. Stainless steel is finding increased use in dairy equipment, as it is able to overcome objections to certain other metals. Describes its use for lining pasteurizers and storage and truck tanks. MS (14b)

New Applications of Nickel Steels and Alloys. *Machinery,* N. Y., Vol. 42, Jan. 1936, pages 318-320. Recent progress in the uses of Ni steels and alloys in the mechanical industries is reviewed and examples are described. Ha (14b)

The Motohome—a Prefabricated Steel-Frame House. *Iron Age,* Vol. 136, Nov. 7, 1935, pages 35-37, 100. Describes a prefabricated steel frame house developed by American Houses, Inc., New York. Amount of steel used in construction of "Motohome" ranges from 1 1/2 tons for smallest model, with 4 rooms and bath, to 2 1/4 tons for a 7 room house. VSP (14b)

Aluminum's Future. W. S. McArdle. *Scientific American,* Vol. 154, Feb. 1936, pages 65-67. Applications and development of Al alloys are traced. CBJ (14b)

Nitralloy Cylinder Barrels for Airplane Engines. Edwin F. Cone. *Metals & Alloys,* Vol. 7, May 1936, pages 119-121. Describes forging and heat treatment of airplane cylinder barrels made of nitralloy from hot rolled bar stock to assembly in engines. WLC (14b)

Sheet Metal Base for Bath Tubs Competes with Cast Iron. Bennett Chapple. *Metal Progress,* Vol. 29, Feb. 1936, pages 47-48. Describes process of production and characteristics of enameled sanitary ware with a 14 gage sheet base. 1/3 less weight results in lower shipping costs and fewer men for installation. WLC (14b)

Steel Rolling Shutters. Ben Frisby. *Power & Works Engineer,* Vol. 31, Jan. 1936, pages 19-21. Various types of steel rolling shutters available are described and illustrated. Their development has afforded savings in floor space, reduction of fire risk and protection against weather, theft, etc. FPP (14b)

Notes on Trends in Nitriding of Steel. Federico Giolitti. *Metal Progress,* Vol. 29, Mar. 1936, pages 68-69. Discusses grades of nitriding steel used in Europe. Application of nitrided steel to regulating needles of hydraulic turbines shows nitrided steel to be twice as good as nearest competitor and 8 1/2 times as good as material costing 1/2 as much. WLC (14b)

What Steel Is Best for This or That Part? William H. Graves. *Metal Progress,* Vol. 29, Apr. 1936, pages 36-42. Gives data on steels used in 6 different automobiles for various parts. Different producers show considerable variation in materials used for same parts. The data indicate that high alloy steels are not commonly in use and that the trend is toward lower alloy content or plain C steels. WLC (14b)

The Dies Used in Brass Die-Casting. Chas. O. Herb. *Machinery,* N. Y., Vol. 42, June 1936, pages 638-640. One of the most satisfactory steels for die-casting dies is composed of W 10-12%, C 0.30-0.40%, Cr 1.75%, V 0.5%. Proper heat treatment, heating to 300°-400° F. before using, preventing the die from becoming hotter than 600° F. in operation, cooling with running water, and daily polishing assure long life. Ha (14b)

Nickel Steels in Railway Engineering. L. W. Johnson. *Railway Gazette,* Vol. 64, Apr. 10, 1936, pages 700-702. Recent intense competition in railroad industry has forced important replacements of wrought Fe and C steel by higher tensile strength alloy steels. Discusses generally beneficial effect of Ni in steel. Composition and physical properties of .20-.25 C steel containing 1.75 to 2.0% Ni for boiler plates and firebox plates are given, and the effect of "aging" on the impact values of various steels with and without Ni is illustrated. Increase in Ni content of low C steels reduces "aging" embrittlement. FPP (14b)

Fundamentals of Light Construction. Part I. (Grundlagen des Leichtbaues. (I Teil)) E. Kreissig. *Stahl und Eisen,* Vol. 56, Jan. 9, 1936, pages 33-39. Safety in thin sections is secured by means of strong, ductile, and corrosion resisting steels. The importance of compressive as well as tensile stresses is emphasized. The influence of welding on the development of light construction is brought out. Various types of hollow beam construction are illustrated. SE (14b)

Fundamentals of Light Construction. Part II. (Grundlagen des Leichtbaues. (II Teil) O. Paulssen. *Stahl und Eisen.* Vol. 56, Jan. 23, 1936, pages 81-86. Light construction in railroads, ships, and airships is discussed. SE (14b)

Principles of Pressure Die Design—Technique for Various Die-Casting Alloys. E. Stevan. *Metal Industry,* London, Vol. 47, Dec. 13, 1935, pages 579-582. As most of the commercial die-casting today is of alloys of Zn, Al, or Cu, die design is determined by the melting point of the alloy to be employed, by contraction factors, by methods of casting and type of machine to be used. The technique of die design must be comprehensive, elastic and is frequently unorthodox since practically each new piece undertaken has its individual problem. Factors to be considered for a new piece, after determining its function and the material from which it is to be made, are methods of production, permissible cost, type of machine most suitable, methods of parting mold, type of core, gating, etc. Tool room equipment should also be taken into consideration. Several types of dies are described. Materials for die construction are dependent upon the quantity required, as cost is a major item. A method that may be used where extreme accuracy is not required is suggested. Methods of parting molds are considered for upon this may depend production that is economical and free from trouble. Some examples are discussed. Different methods are suggested for the removal of cores. HBG (14b)

Metal in Functional Architecture—Its Proponents' Views. F. Charles Thum. *Metal Progress,* Vol. 29, Feb. 1936, pages 43-46. Discoloration of exterior trim near the street level in congested city atmosphere produces results unsatisfactory to builder and owner. Absence of thoroughly adaptable small unit section acts against increased use of metal. WLC (14b)

Armour Plate and Ordinance. *Times* [*London*] *Trade & Engineering,* Vol. 38, Apr. 1936, page XV. Outlines developments in manufacture of armor-plate and ordnance and steels therefor. MS (14b)

Steel Containers for Beverages (Stahlbehälter für Getränke) *Montanistische Rundschau,* Vol. 28, June 16, 1936, (Section *Stahlbau-Technik*) pages 7-8. Hofius, Duisburg, Germany, has developed a process for storing milk in containers of stainless steel. By keeping the milk between definite temperature ranges and under a certain oxygen pressure it has been found possible to keep it fresh for about 2 months, with no change in chemical or bacteriological properties, and with no taste of the steel. Also discusses the use of steel containers for storing and shipping beer, which permit a saving of 40% in weight of packing and 60% in space. BHS (14b)

Heat Resistant Steel for Aeronautic Motors (Eine hitzebeständige Stahlsorte für Flugmotoren) *Montanistische Rundschau,* Vol. 28, June 16, 1936, (Section *Stahlbau-Technik*) page 7. Tests at the Moscow Institute for Aeronautic Materials have shown that an 18:8 steel containing Ti and a high percentage of Si gives very good service in the exhaust system of aeronautic motors. It has heat resistance, strength and elasticity at elevated temperatures, and is easily welded. Yield point 25-30 kg./mm.^{2}; elongation 45-55%; hardness 165-180 Brinell. BHS (14b)

Properties of Principal Cr-Fe and Cr-Ni-Fe Alloys. *Metal Progress,* Vol. 29, June 1936, pages 56-57. Tables showing properties of these alloys. WLC (14b)

RICHARD RIMBACH, SECTION EDITOR

Report for the Year 1935. National Physical Laboratory. His Majesty's Stationery Office, London, 1936. Paper, 8 x 10¾ inches, 249 pages. Price 12s.

Among metallurgical problems under investigation in 1935 were X-ray study of cold worked metals of electrodeposited coatings of transformer steels and of metal undergoing fatigue. In the last, fragmentation was noted at stresses that would ultimately cause failure. CuCr alloys for resistance standards are being tried. Wear of metals, ductility testing of thin sheet, Al under alternating torsion, fatigue under combined stresses, with different surface conditions, and in different atmospheres and corrosive media, creep and stability of C and CMo steels, high temperature properties of gaskets and bolting materials, cracking of boiler plate, journal friction, strength of welds, Ti and Al alloys, contact corrosion under pressure, seizing of bearings, tests of cast crankshaft materials, pure Fe and pure Fe-C alloys, oxidation of metals, analytical methods, AlCuSi alloys, solubility of H_2 in Al, MgCdAlAg, grain size and "heredity" in Al alloys, growth of cast iron, gases and oxides in steel and dental alloys were all given attention. The work is carried on in the departments of metallurgy, engineering and physics.

Technical Teaching in Theory and Practice. C. H. Creasey. George Routledge & Sons, Ltd., London, 1935. Cloth, 5 x 7½ inches, 151 pages. Price 3s. 6d.

The author has spent 39 years in the British Colleges and technical schools, "during which time he has had unusual opportunities of observing the discouragement and economic loss which results from each generation of teachers having to carry on their work without special training or the benefit of transmitted experience . . . The book is the result not merely of observation and teaching experience, but of hundreds of lectures, formal and informal discussions, and talks to many types of teachers, in a wide variety of subjects, over a long period of time."

The book contains the following chapters: How the Mind Works; The Devices of Teaching; General and Special Methods; and Personal Relations. This information will not only be of value to educator but also to the operating executive, who must also convey information but often under extremely unfavorable circumstances.

Fire Risks on Magnesium Alloys. *Aluminium & Non-Ferrous Review,* Vol. 1, May 1936, pages 373-375. Reports by Fire Brigade officers on the ignition of Elektron swarf are reproduced and criticized. Liquid extinguishers should not be used, but the fire smothered with asbestos cloths or sand. JCC (15)

Investigation of Accidents on Niter Baths (Untersuchung von Unfallereignissen an Salpeterbädern) Haid & Frenzel. *Oberflächentechnik,* Vol. 13, May 5, 1936, pages 102-103. A number of cases are described where serious explosions occurred when pieces of light metal were treated in a melt of K-Na nitrate at 500° C. The reason is usually a very strong reaction between the Fe container and the melt due to a thermite-like mixture of Fe oxide and pieces of Al which ignite and melt the container so that the molten mass runs out. The reaction is started by local overheating of the container. At ordinary temperatures of the baths, Al is quite inert against the molten niter and cannot be ignited even by burning material dipped into the bath. If the temperature is, however, sufficiently high a strong reaction of the melt with even solid Al takes place which is still more favored by the fact that Al above its melting point (657° C.) absorbs liquid niter like a sponge. It is recommended always to supervise the bath and to prevent the temperature from rising above 600° C. Al collecting in the bath should be regularly removed. Ha (15)

Secondary Copper. Its Production, Consumption, and Market Effect. Percy E. Barbour. Mining & Metallurgical Society of America, New York, 1936. Paper, 6 x 9 inches, 85 pages. Price $1.50.

This study, according to the preface, is presented as a report from the Committee on Foreign and Domestic Mining Policy of the Society, but it should be pointed out that the opinions expressed are those of an individual and should therefore be taken as such. This in no way reflects upon Mr. Barbour's ability to treat a most difficult subject as we know of no individual better qualified to pass judgment on secondary Cu than the author.

The report deals fundamentally with the statistical and economic position of secondary Cu as it affects the market for the primary metal. It is therefore a treatise in which the average metallurgical engineer will find little of interest unless he is one of the school that appreciates that in this day and age the purely technical and economic aspects of any problem must be considered jointly.

Following a brief discussion of plants, classification and sources of secondary materials, the author launches into a presentation of statistical data on scrap and secondary Cu in their relation to primary, or virgin, metal. Although ample data are presented, one who is just being introduced to the subject will find it difficult to understanad and appraise the numerous factors which play important roles in affecting markets for both secondary and primary. We become imbued with the idea that secondary Cu is really only a small part of the industry and statistically this may be true, but it has a much more important effect on markets than would be inferred from Mr. Barbour's discussion. We must also assume from the phraseology employed that under normal conditions the price of refinery Cu has no material effect on secondary production or on the market price of Cu. These statements may be acceptable within certain limits but there are so many different conditions to analyze that it is not within the scope of this review to consider them.

We must not lose sight of the fact that all Cu rich scrap is Cu, when appraised from the secondary angle. Materials falling into this category are always a threat to the stability of the primary market as they directly and indirectly affect the price structure.

This work will serve as an excellent introduction to a phase of the industry which is becoming increasingly important. Although we cannot whole-heartedly agree with certain conclusions drawn by the author, we highly recommend the report as the most complete treatise yet published on the fascinating and complex subject of secondary Cu. FREE SERVICE DEPARTMENT

Wanted:—By a well-known manufacturer of Heat and Acid Resisting Castings Sales Representatives who are acquainted with buyers and operating heads in the Steel, Automobile, Chemical and Oil Industries in the following territories: New York, Boston, Philadelphia, Chicago, Cincinnati, Houston and Birmingham. No objection to one or two more lines. Reply giving references and full information as to qualifications. Address Box MA-2, Care of Metals & Alloys, 330 W. 42nd St., New York, N. Y.

REPRESENTATIVE WANTED—A manufacturer of heat resisting alloys and castings seeks representation in both the Philadelphia and New England territories. We are looking for a manufacturer's representative now calling on metal working plants who has the entree to the heat treating supplies market. Write Box No. MA-3, METALS & ALLOYS, 330 42nd Street, New York, N. Y.

Junior Executive Available—M. I. T. Graduate. General engineering experience, Chase Brass and Copper Company. Purchasing chemicals and equipment, R. H. Macy and Company. Single, Christian, references. Box No. MA-4, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

POSITION WANTED: INSPECTOR, SUPERVISOR or INSTRUCTOR of WELDING. Specialized 8 years in arc welding. Knowledge of Metallography, Heat-Treating and Physical Metallurgy. Capable of performing tests and conducting investigations of Weld-Metal. Sales experience. Member of American Welding Socy. and American Socy. for Metals. Good Linguist. Consider position outside U. S. Available July First. Address box MA-6, care of METALS & ALLOYS, 330 W. 42nd Street, New York, N. Y.

MARKET RESEARCH SPECIALIST with a good technical background. Complete developing and marketing experience on electrical and chemical specialties and instruments. Salary or fee basis. Box MA-9, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

METALLURGIST, TESTING, OR RESEARCH ENGINEER POSITION WANTED: Age 29. Five years' experience in physical metallurgy, metallography, material testing, including fatigue, at temperatures from +70° F. to —50° F., metal inspection, and design of special testing machine equipment. Some experience in heat treating. University graduate, M. S. degree. Now employed on nearly completed investigation. Available on or before Jan. 1st. Box MA-10, Metals & Alloys, 330 West 42nd Street, New York, N. Y.

REPRESENTATIVE WANTED: Industrial furnace manufacturer wants experienced sales engineer familiar with middle west territory and with some metallurgical knowledge. Commission bassis. Address Box MA-12, c/o METALS & ALLOYS, 330 West 42nd St., New York, N. Y.

AVAILABLE — METALLURGIST — Technical graduate — 35 years—8 years metallurgical supervision over all phases of special ssteel manufacture, including melting. Address Box MA-11, c/o METALS & ALLOYS, 330 West 42nd St., New York, N. Y.

WANTED: By large, well-known buyer of Metal Alloys and Residues containing Nickel, Chrome, Etc.—Representatives who are acquainted with the Steel—Chemical—Heat Treating, Heat Resisting, and Automobile Industries. We offer a very attractive proposition to the right man. Reply, giving references and qualifications. Also, cities and states which you cover. All references and qualifications will be kept strictly confidential. Box MA-13, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

WELDING ENGINEER, metallurgical experience with sales background. Experience in design, estimating and research, sheet metal and heavy structures. Not actively employed at present. Permanent connection desired. Box MA-14, care of METALS & ALLOYS, 330 West 42nd St., New York, N. Y.

CURRENT NEWS ITEMS

Harry E. Sheldon Honored

An inter-community holiday and celebration, sponsored by a committee of the Upper Allegheny Valley Citizenry, was held in Brackenridge, Pa., Sept. 17, in recognition of the civic benefactions of Harry E. Sheldon, 75 year old founder-president of the Allegheny Steel Co. The communities of Tarentum, Natrona Heights, Harrison Township and Brackenridge, Pa., in which the principal plants of the company are situated and in which most of the employees live, organized the celebration but delegations from most of the communities within a five mile radius participated.

More than 10,000 children, volunteer firemen, American Legionnaires, steel mill workers, member of civic organizations and plain citizens took part in a parade which required more than 2 hours to pass the reviewing stand. Included were 84 employees, still active in the company, who started with Mr. Sheldon when it was organized 35 years ago.

Mr. Sheldon was referred to as the founder of stainless steel in America, and the creator of an enterprise bringing work and homes to thousands. He was presented with a stainless steel plaque by S. M. Hazlett, chairman of the Citizens Committee as a testimonial of the associated communities, who pointed out that Mr. Sheldon's enterprises has brought over $120,000,000 in wages to the communities in 35 years and has furnished with but one or two brief interruptions continuous employment for thousands of men during that time.

International Acetylene Association to Meet in St. Louis

The International Acetylene Association will hold its thirty-seventh annual convention in St. Louis at the Jefferson Hotel, Nov. 18, 19 and 20. This will be the first time that the convention has been held in St. Louis.

Technical sessions will be held each afternoon and on two evenings. The oxy-acetylene process for welding and cutting metals will be featured at these sessions. As the result of a year of unusual developments, a series of vitally interesting subjects will be discussed by speakers who are key men in their fields. Wednesday evening, Nov. 18, is to be devoted to a forum on welding and cutting. The evening session, Thursday, Nov. 19, is intended to comprise a series of popular round-table discussions on oxy-acetylene welding and cutting practices.

Dr. Warner to Teach Metallurgy at Carnegie

Dr. J. C. Warner, associate profesor of theoretical chemistry and for the past ten years a member of the faculty of the chemistry department at the Carnegie Institute of Technology, has been appointed associate professor of metallurgy at Tech, effective at the beginning of the fall term.

An authority on physical chemistry, Dr. Warner will develop a teaching and research program in this field as it applies to the melting and refining of metals. Having already organized an extensive program of research in metals, Tech now plans to develop an experimental laboratory for undergraduates in process metallurgy. The melting and refining of metals offers a particularly appropriate field for Carnegie to emphasize, located as it is in the center of the iron and steel industry.

J. Fletcher Harper has resigned as research engineer with the Allis-Chalmers Mfg. Co., Wilwaukee, to become associated with the **Globe-Union Mfg. Co.** of the same city, makers of storage batteries, radio parts, steel roller skates and so on. Mr. Harper was graduated from the college of engineering of the University of Wisconsin and is widely known in metallurgical circles. He is a past president of the American Society for Metals. Harold Stein has been appointed to succeed Mr. Harper. He is a graduate of Tri-State College and has been with the Allis-Chalmers company since 1916.

Symposium on Corrosion Resistant Metals for Machinery

A remarkable symposium on "Corrosion Resistant Metals in Design of Machinery and Equipment" will be held as part of the American Society of Mechanical Engineers' annual meeting in New York, Nov. 30 to Dec. 4. The information presented is to be in compact form, of a practical nature, free from lengthy theoretical discussions but still sufficiently complete that when the different papers are assembled they will form a handy reference for the engineer of the subject of corrosion resistant metals.

The need for such a symposium was expressed by designing and operating engineers of the country who are constantly confronted with many problems on corrosion. They are busy men and not many of them have been able to follow closely the rapid development of this type of information during the past few years. Several of the professional divisions of the society joined in developing the symposium making it a feature of the A.S.M.E. annual meeting where it has been allotted the whole day of Thursday, Dec. 3 with three sessions in the morning, afternoon and evening. T. H. Wickenden, past chairman of the Society's iron and steel division, was appointed chairman of the committee that is arranging the symposium.

Several methods of presentation had been considered to present the material but the most feasible appeared to be according to the different base metals. The papers to be presented are as follows:

"Introduction to Corrosion Resisting Metals" by Dr. F. N. Speller, National Tube Co., Pittsburgh.

"Alloys of Aluminum" by E. H. Dix, Jr., Aluminum Co. of America, New Kensington, Pa.

"Nickel and Nickel-Base Alloys" by F. L. LaQue, The International Nickel Co., Inc., New York.

"Zinc in the Chemical Industries" by E. A. Anderson, The New Jersey Zinc Co., Palmerton, Pa.

"Lead" by G. O. Hiers, National Lead Co., Brooklyn.

"Cast Iron in Chemical Equipment" by Dr. H. L. Maxwell, E. I. du Pont de Nemours Co., Inc., Wilmington, Del.

"Copper and Copper-Base Alloys" by R. A. Wilkins, Revere Copper & Brass, Inc., Rome, N. Y.

"Corrosion Resistant Steel (Stainless Type)" by J. H. Critchett, Union Carbide & Carbon Research Laboratories, Inc., New York.

Notre Dame Adds to Its Metallurgical Staff

Continued growth of interest in the field of metallurgy and the notable increase in enrollment in metallurgical courses at the University of Notre Dame have this year made necessary an addition to the teaching staff of the department of metallurgy. Dr. Carl F. Floe comes to the department from Washington State College, where he has been teaching metallurgy for several years. He takes the position of assistant professor of metallurgy, in charge of non-ferrous work. Dr. Floe is a graduate of Massachusetts Institute of Technology, where he received the doctorate in 1935.

A new firm, **Patton & Bruce,** has been formed in St. Louis to represent the boiler water conditioning and combustion control interests of the **Hagan Corp.,** of Pittsburgh, and its affiliates, Hall Laboratories, Inc., and The Buromin Co. Members of the firm are Russell Patton and Warren C. Bruce, located at 526 North Vandeventer Ave.

The New York office of **The Timken Steel & Tube Co., Arthur R. Adelberg,** district manager, is now located at 165 Broadway, Room 1000. Mr. Adelberg formerly had his office in The Timken Roller Bearing Co. offices at 16 W. 60th St.

An actual demonstration of how porcelain enamel is fused on metal will be presented by the Porcelain Enamel Institute during the American Gas Association Convention in Atlantic City, Oct. 25 to 30. This will be the same demonstration which the Institute's Educational Bureau has been conducting in department stores throughout the country during the last year. Porcelain enameled ash trays will be manufactured to show visitors at the convention how the porcelian enamel finish on their gas appliances is applied.

Contests in 1937 for Apprentices in Moulding and Pattern Making

The American Foundrymen's Association announces that the molding and pattern making contests, which met with such success at the May, 1936, convention, will again be held in 1937. The contests will be sponsored by the Association Committee on Foundry Apprentice Training, and competition will be held definitely in steel molding, iron molding and pattern making classes. If sufficient interest is evinced in the Non-Ferrous field, a competition will be authorized in that group also. First, second and third prizes of $40, $25 and $15 will be awarded in each class from entries sent to the 1937 Convention.

Regulations of the Committee provide that local contests may be held under the supervision of individual foundries or of foundry groups. Copies of the regulations may be secured by writing to the A. F. A. at 222 West Adams St., Chicago. The Apprentice Training Committee is composed of men who have had wide experience, and is representative of foundries of various types.

Foundry Conference at University of Iowa

The American Foundrymen's Association announces that an important two-day conference on foundry practice will be held at the University of Iowa, Iowa City, Iowa, Friday and Saturday, Oct. 30 and 31. The conference is being sponsored by the College of Engineering of the University, the A. F. A. through its Quad-City Chapter, and the Northern Iowa Foundrymen's Association.

The program will consist of sessions on melting practice, and control and other current foundry problems. Outstanding experts will give the talks and lead the discussions. The detailed program will be announced later.

This conference will be similar to the annual district conferences held at Michigan State College, East Lansing, Mich., last year, and is one of the several which the A. F. A. is assisting in developing for the purpose of bringing foundrymen together to discus their mutual problems.

"Carilloy" Alloy Steels

Announcement of the new trade name, "USS CARILLOY," to identify alloy steels produced by Carnegie-Illinois Steel Corp. has been made by this subsidiary of United States Steel Corp.

It is emphasized in the announcement that the new name "USS CARILLOY" does not signify a new product, nor does it apply to any single alloy steel. It is simply a new trade designation which will serve as a quality trademark for the entire group of well-known alloy steels previously marketed as "Carnegie-Illinois Alloy Steels."

Advertisements in current trade publications feature "USS CARILLOY" which is reproduced in a distinctive hand-lettered logotype that makes the new name a trademark as well as a product brand name.

The **Cooper Alloy Foundry Co.**, Elizabeth, N. J., announces a division through which is extended a new service. One of the original and largest producers of stainless steel castings since 1927, it has made special note of the shortcomings in alloy machining. In opening its new branch, it has incorporated principles that rectify former mistakes and remedy old deficiencies. The **Stainless Engineering & Machine Works** has been organized to supply a specialized machine work adapted to stainless and heat resisting metals. Informed by an able staff and equipped with adequate machinery, it is in a position to design and construct with any alloy, in particular stainless steel. The officials are Harry A. Cooper, president, and M. J. Roberts, vice-president and general manager.

The appointment of **Frank J. Laskey** as general purchasing agent for **Republic Steel Corp.**, Cleveland, has been announced by Carl A. Ilgenfritz, manager of purchases and raw materials. **Robert E. Sherratt** has been named assistant general purchasing agent.

Frederick S. Cook has been appointed Pacific Coast manager for **Robert W. Hunt Co.**, engineers, with headquarters at San Francisco.

Value of Census Figures to Industry

At a recent luncheon at the Metals and Minerals Exhibit, International Building, Rockefeller Center, New York, Dr. Vergil D. Reed, assistant director of the Bureau of Census, spoke on the vast value and importance of figures being constantly compiled by the Bureau.

The Bureau of Census, U. S. Department of Commerce, will have Mervyn V. Pallister in New York during the months of September and October, to acquaint business men in general with the vast amount of research material available through the Bureau of Census. This is the first time that the government has established this service anywhere outside of Washington. In a survey conducted on who uses the government Census figures, it was discovered that advertising agencies lead all others, manufacturers being second, and newspapers third. The data are very comprehensive, and of wide value to anyone interested in marketing, manufacturing, market analysis, plant or store location, sales territories, consumer analysis, industrial trends, etc. Mr. Pallister is making his headquarters at the Metal Products Exhibits, Inc., International Building, Rockefeller Center.

Lukenweld Elects New President

Everett Chapman, who has been vice president of Lukenweld, Inc., Coatesville, Pa., has been elected president of the company, according to an announcement by Robert W. Wolcott, president of Lukens Steel Company, of which the Lukenweld organization is a division. Mr. Chapman succeeds G. Donald Spackman, who was recently promoted to general superintendent of Lukens Steel Co.

Robert J. Whiting, who has been superintendent of Lukenweld, Inc., in charge of all manufacturing, has been elected vice president of Lukenweld, Inc.

Personals

M. H. Mawhinney has terminated his connection with the Salem Engineering Co., Salem, Ohio, and is now engaged in special consulting work.

E. J. Edwards, for many years engineer of tests for the American Locomotive Co., Schnectady, N. Y., has been promoted to chief metallurgical engineer. He is succeeded as engineer of tests by L. F. Mulholland.

H. Foster Bain is now with Samuel H. Dalbear and Lawrence B. Wright, mining engineers, New York.

T. L. Joseph has resigned from the Bureau of Mines to take a position as professor of metallurgy with the Minnesota School of Mines and Metallurgy. Mr. Joseph has conducted blast furnace investigations for the Bureau of Mines since 1919. For the past year he supervised a plant investigation conducted jointly by the Inland Steel Co., and the Bureau of Mines on the effect of oxides in pig iron on the oxides in basic open-hearth steel. F. W. Scott, who made the oxide determinations in this investigation, has resigned from the Inland Steel Co. and will be associated with Mr. Joseph in teaching and in conducting research.

Harry L. Campbell, for many years on the faculty of the University of Michigan has become associated with the American Hoist & Derrick Co., St. Paul, Minn., as metallurgical engineer.

Samuel Epstein, formerly associated with Battelle Memorial Institute, is now with the research and development department of the Bethlehem Steel Co., Bethlehem, Pa.

The Westinghouse Award, Order of Merit, has been conferred on **Norman L. Mochel**, metallurgical engineer, by the Westinghouse Electric & Mfg. Co., "for distinguished service to the industry in the field of metallurgy."

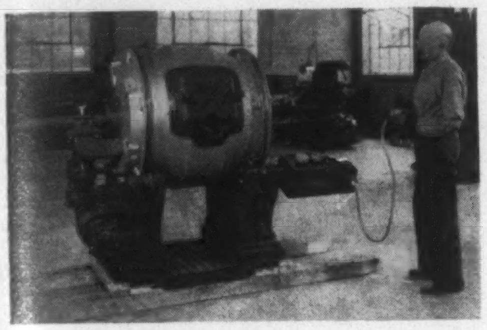
Further expanding its metallurgical service in the Detroit area, the **Union Drawn Steel Co.**, Massillon, Ohio, has announced the addition of **James R. Buchanan** to the field metallurgical staff of its Detroit district sales office.

NEW EQUIPMENT AND MATERIALS

New Detroit Rocking Furnace

A new 350-lb. furnace, "Type LFC," for high temperature melting, is announced by Detroit Electric Furnace Co., Detroit. It has been specially designed for melting copper, nickel, and alloy irons and steels.

A major change from the model LFA which it replaces is that the arc at the center of the furnace is farther away from the refractory than at the ends of the shell. The new shell is of larger diameter around the central portion than at the ends. A changed hearth design permits easier tapping and cleaning.



The new furnace is equipped with automatic rocking control, which is a recent development of the company, and likewise with a remote pouring switch which can be operated at some distance from the unit. A magnetic brake motor is included as standard equipment on the rocking mechanism.

It is believed that the improvements in the refractory and shell will result in longer refractory life, reduced power and electrode consumption, and a decrease in metal loss in the highly volatile alloys.

The shell and refractory design are such that the metal is constantly brought back to the hottest part of the furnace, being that part immediately adjacent to the arc, so that there is a constant action to provide a uniform temperature throughout the bath.

"Coppercote"—A Preservative Coating for Metals, etc.

Pure metallic copper of extreme fineness and of the irregular flaky structure known as "dendritic" can now be applied to iron, steel, wood, concrete, or other surfaces which require a protective coating of unusual effectiveness. This new coating is being produced under the name "Coppercote" and has been thoroughly tested, according to American Coppercote, Inc., New York.

Many corrosion problems were taken into account in the development of Coppercote which involved the production of a special vehicle in which the minute flakes of pure metallic copper remain in perfect suspension. While the coating is applied, a physico-chemical reaction occurs between the particles of copper and its vehicle. Since the copper is "dendritic" in structure rather than granular, a closely knit coating results which, when set, forms a tough hard metallic surface. When applied to a surface of ferrous metal it will positively prevent corrosion. When applied to a surface already rusted, it will arrest any further corrosive action. It will not crack, scale nor chip as a result of the extremes of temperature nor is it affected by the ultra violet rays of the sun. Coppercote has been demonstrated to be a non-conductor of electricity. Due to the insulative character of the coating, destructive electrolytic action is impossible.

Coppercote has been applied to steel columns under conditions of extreme dampness in the Eighth Ave. Subway, New York City. Perfect protection is still being given after a year of service.

Deeply corroded specimens of angle iron were treated with Coppercote and buried in coal cinders for one year. At the end of this period they were unearthed and found to be in perfect condition.

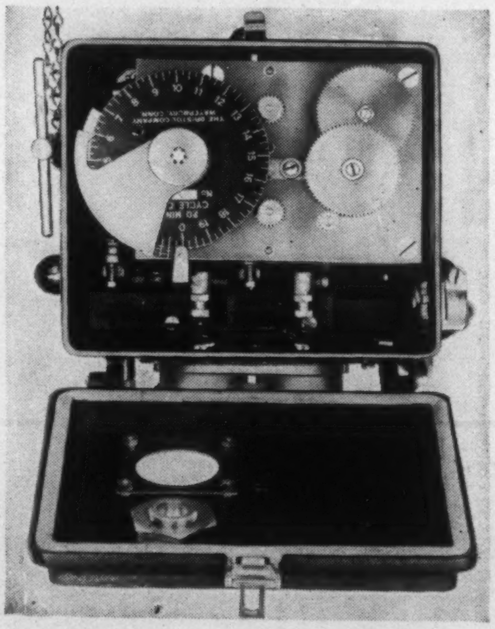
Steel specimens coated with Coppercote were buried in alkaline soil for two years. When dug up, they were found to be unaffected.

Coppercote coated steel panels were found to be unaffected by gasoline after immersion for extended periods of time.

It has been demonstrated that the application of Coppercote to wooden structures provides effective protection against the termite and also against marine borers including the teredo and limnoria. Coppercote is extremely fire resistant and its application to wooden structures will greatly reduce fire hazards.

New Process Cycle Controller

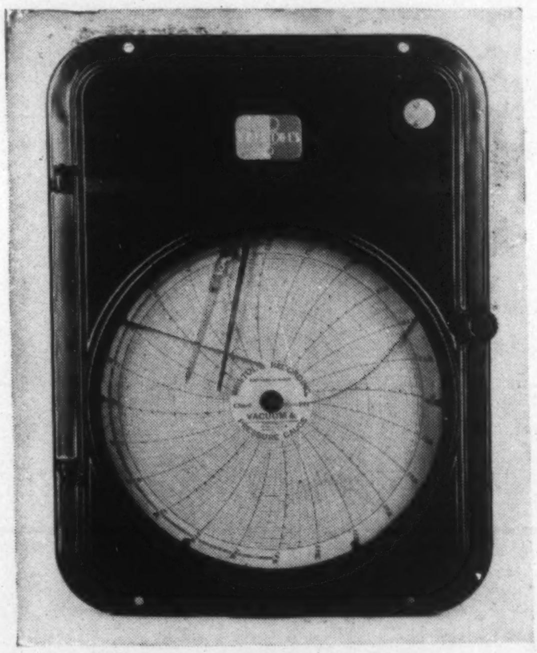
The Bristol Co., Waterbury, Conn., has developed a new process cycle controller, known as the "Model 6088V," to fulfill the many requirements, particularly in the rubber and molded plastics industries, where a variable speed controller is required. This instrument is suitable for automatically controlling any cycle operation which operates on a cycle that must be changed from time to time. It is equipped with one cam operating one or two patented, leakless, three-way pilot valves, as required by the process. The cam is readily adjustable to carry out any desired time cycle, regardless of duration, within the range of the controller cam.



A novel two-speed cam operating mechanism makes possible a multiplicity of speeds obtainable with but a single cam. The variable speed mechanism employed involves no gear shifts, governors, springs, or escapements. It is extremely simple in construction.

New Low-Range Pressure Recorders and Controllers

The Bristol Co., Waterbury, Conn., announces a new series of low-range recording gages and controllers, known as the Model D40M series. These instruments are equipped with enclosed bell-type measuring elements and are offered for draft or pressure in minimum ranges of 0 to 0.2 in. of water and maximum ranges of 0 to 2.0 in. of water. Because of the large operating area of the liquid-sealed bell, the measuring element is exceedingly accurate and has the power to respond instantaneously to scarcely perceptible pressure changes.



The control instruments operate on the basic "Free Vane" principle of pneumatic control which Bristol has used extensively in pressure, vacuum, temperature, humidity, and flow controllers for years. They are equipped with the "Ampliset" sensitivity adjustment for synchronizing throttling range with process lag.

Instruments of this series are compact and self-contained in a 12-in. case. The whole instrument can be easily carried under the arm. Low-Range Model D40M recorders and controllers are offered for wall and flush panel mounting.

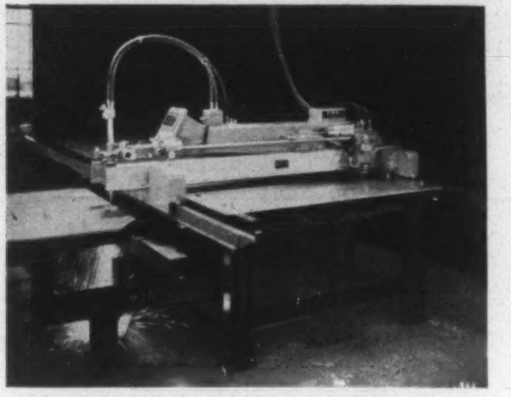
The Lea String Brush

The Lea Mfg. Co., Waterbury, Conn., has developed a type of brush known as the "Lea String Brush" for use in conjunction with the Lea method of metal finishing. In the past it has been necessary to use cloth buffs for producing satin and Butler finishes by the Lea method. With this development articles having contours and ornamentations can be even more quickly and more economically finished by the Lea method, using the new Lea String Brush. This brush is more pliable than a cloth buffing wheel and therefore permits the flexible surface when coated with Lea compound to get into the various contours of many intricately shaped articles. With the Lea String Brush, finishes can be produced ranging from a very dull satin to a bright Butler.

Oxweld Shape Cutting Machine

Introduction of the new "Oxweld Type CM-12" Shape Cutting Machine by The Linde Air Products Co., New York, makes available to the metal-working industries a machine designed to give the accuracy and range of work demanded more and more of the flame cutting processes. Its precision, simplicity and economy of operation will widen the scope of shape cutting.

The flexibility of this machine allows for almost limitless possibilities for its use. It is more powerful and has a greater cutting capacity than any other machine in its class. Any shape, from the simplest to the most complicated, can be accurately produced either automatically with templets or guided by hand. The immediate transfer of motion from one end of the machine to the other is a factor in assuring precision in all cutting operations.



In addition to cutting shapes of all description, the machine will cut straight lines automatically in any direction and at any bevel. Cuts as long as 144 in. are possible and an important feature lies in the fact that straight line cuts can be made at any desired angle in the horizontal plane. A special circle cutting attachment is also provided, thus enabling the automatic production of circles from 2 to 24 in. in radius. Still another feature is that of multiple cutting. The apparatus is designed to carry from 2 to 5 blowpipes which can perform multiple cutting operations under all the conditions possible with a single blowpipe.

The features of design and construction which makes possible the accomplishments of this new shape cutting machine typify the trend in modern machine development. Alloys have been utilized to establish an ideal strength-weight ratio combined with the necessary stability and rigidity of construction. Complete enclosure of the vital working parts insures correct lubrication and freedom from maintenance. The motor, rated at 1/3 h.p., produces a driving force reliable under all conditions. The speed range of the CM-12 is from 1½ to 75 in. per min.

Plating Solution Control

It is announced by the Grasselli Chemical Co., Cleveland, that it is in a position to offer the trade test kits for the control of cadmium and zinc plating solutions. Three kits have been developed for this purpose:

1. For the determination of cadmium in cadmium-cyanide plating solutions.
2. For the determination of zinc in alkali-cyanide or acid-zinc plating solutions.
3. For the determination of the total sodium-cyanide content in zinc or cadmium plating solutions.

As nearly all previous methods of determining these constituents were either inaccurate, unreliable or intolerably slow, the company sought to develop a method that would be an accurate, reliable and quick means of finding the concentration of these constituents in the plating bath.

It is stated that these test sets are easy to manipulate. In organizations where centralized laboratory control is available, it has been ascertained that the plater finds these test kits of great value, especially when the information they can give is required in a brief period of time.

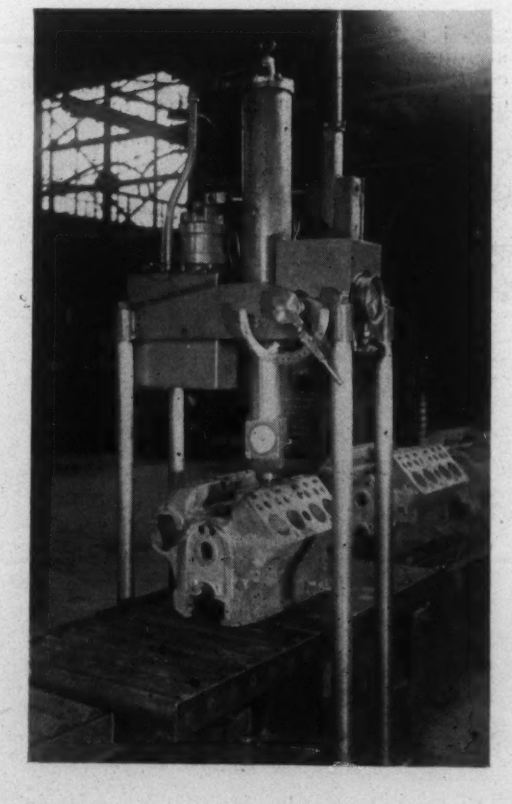
These test sets for solution control supplement the Hull and Strausser test sets announced by Grasselli a few months ago for determining the thickness of electrodeposited cadmium or zinc coatings.

There is an increasing demand for coatings of specified thickness. These developments make it convenient for the plater to determine the composition of his plating bath and in that way keep it in the most efficient condition, enabling him to apply the specified coating thickness of cadmium or zinc in the minimum plating time.

Direct Reading Conveyor Brinell

This machine is developed by the Detroit Testing Machine Co., Detroit, for testing cylinder blocks, cylinder heads, die blocks, etc., on a conveyor without elevating them to the testing position. The ram, being the moving member, has a travel of 24 inches. It is operated in the same manner as that of a steam hammer and may be held at a height to accommodate the size of blocks on production. The conveyor section is spring mounted, which permits the blocks to set on a solid support when the load is applied.

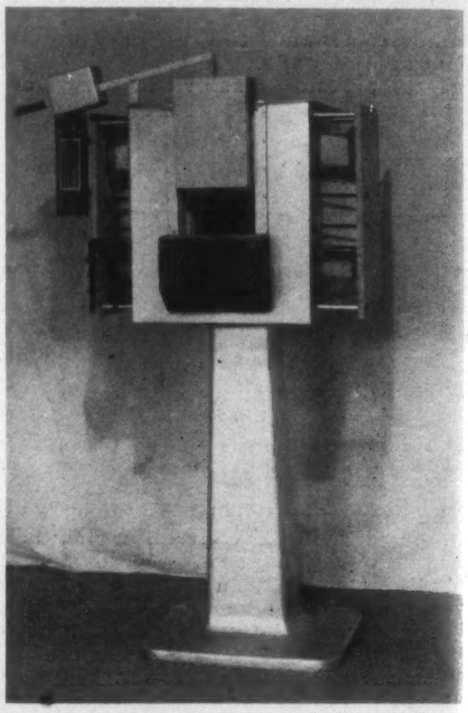
The direct reading device is the same as in the company's standard Brinell power machines and is mechanical throughout. Tests can be made without grinding or spotting and the use of a microscope. After tolerance bands are set to the desired limits, the operator merely notes that the indicator pointer stops within them. Since the actual test made is the standard Brinell, accuracy may be conveniently checked with a microscope.



Oil is used as a pressure medium assuring thorough lubrication and long life. This oil is kept at a constant temperature with a thermostatically controlled heating element and is not subject to viscosity changes, due to varying temperatures. The machine is simple in construction, easy to operate and accurate in performance.

Furnace for Hardening High Speed Steel

About a year ago the Sentry Co., Foxboro, Mass., announced its new small furnace for hardening high speed steel. This size, No. 1, Model "Y" furnace, for the first time offered outstanding advantages of quality, reliability, and economy, and created a demand for a larger size furnace of the same style. The company is now introducing size No. 2, Model "Y", furnace. Like its smaller predecessor, size No. 2 is a muffle furnace with four heating elements, two above and two below the muffle. It employs air-cooled terminals which eliminate complicated cooling water connections and will give several years' service without attention. Terminals and all electrical contacts are shielded and heating elements give well over 1000 hrs. service.



The No. 2 "Y" will heat from cold to 2350 deg. F. in 70 min. The current consumption at 2350 deg. F. is between 4½ and 9 kw. depending on the amount of work hardened. The furnace is adequately insulated and power costs are extremely low as indicated above. The furnace is designed especially to secure the full advantages of the Sentry "Diamond Block Method" of atmospheric control and has a muffle chamber 4½ in. wide, 4 in. high by 11 in. deep and will accommodate the five standard Diamond Block sizes. The furnace can be supplied with any standard make of temperature control or connected to suitable control equipment. It can be supplied either with pedestal or for bench mounting and can also be equipped with a gas curtain.

A Castable Refractory

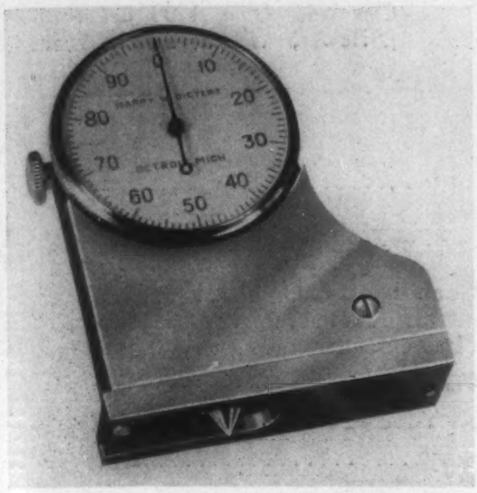
"Cast-Refract" is a time and labor-saving castable refractory, marketed by the Quigley Co., New York. It is handled like concrete, and can be cast into any desired shape or form. It is invaluable for casting special refractory shapes needed in a hurry (ready to use in 24 hrs.) and has many other uses—including monolithic furnace linings, boiler door arches and jambs, furnace door linings, etc. Its convenience and adaptability are features of wide appeal to engineers concerned with furnace operation and maintenance.

The recommended service temperature limit of this product is 2600 deg. F., within which it possesses excellent general refractory properties: A strength, freedom from shrinkage, low permeability, and outstanding resistance to spalling.

Core Hardness Tester

The surface hardness of cores and dried molds may be quickly measured with this instrument, built by Harry W. Dietsch Co., Detroit. Its net weight is 9 oz.; shipping weight, 18 oz.; height, 3 in.; and width, ¾ in.

The Core Hardness Tester is a practical tool and may be carried around without inconvenience by foundrymen.



The hardness of a core may be determined within a few seconds. A test is made by grasping the tester with the right hand and pressing it against the surface to be tested. Slowly pull the tester across the face of surface to be tested. Hardness of surface is indicated on dial.

The principle of this tester is similar to the finger nail scratch test that a foundryman uses to estimate the hardness of cores and dried molds. The difference between the finger nail test and the core hardness tester is that the hardness of surface is accurately determined with the core hardness tester and expressed in numerical figures that may be recorded for definite comparative purposes.

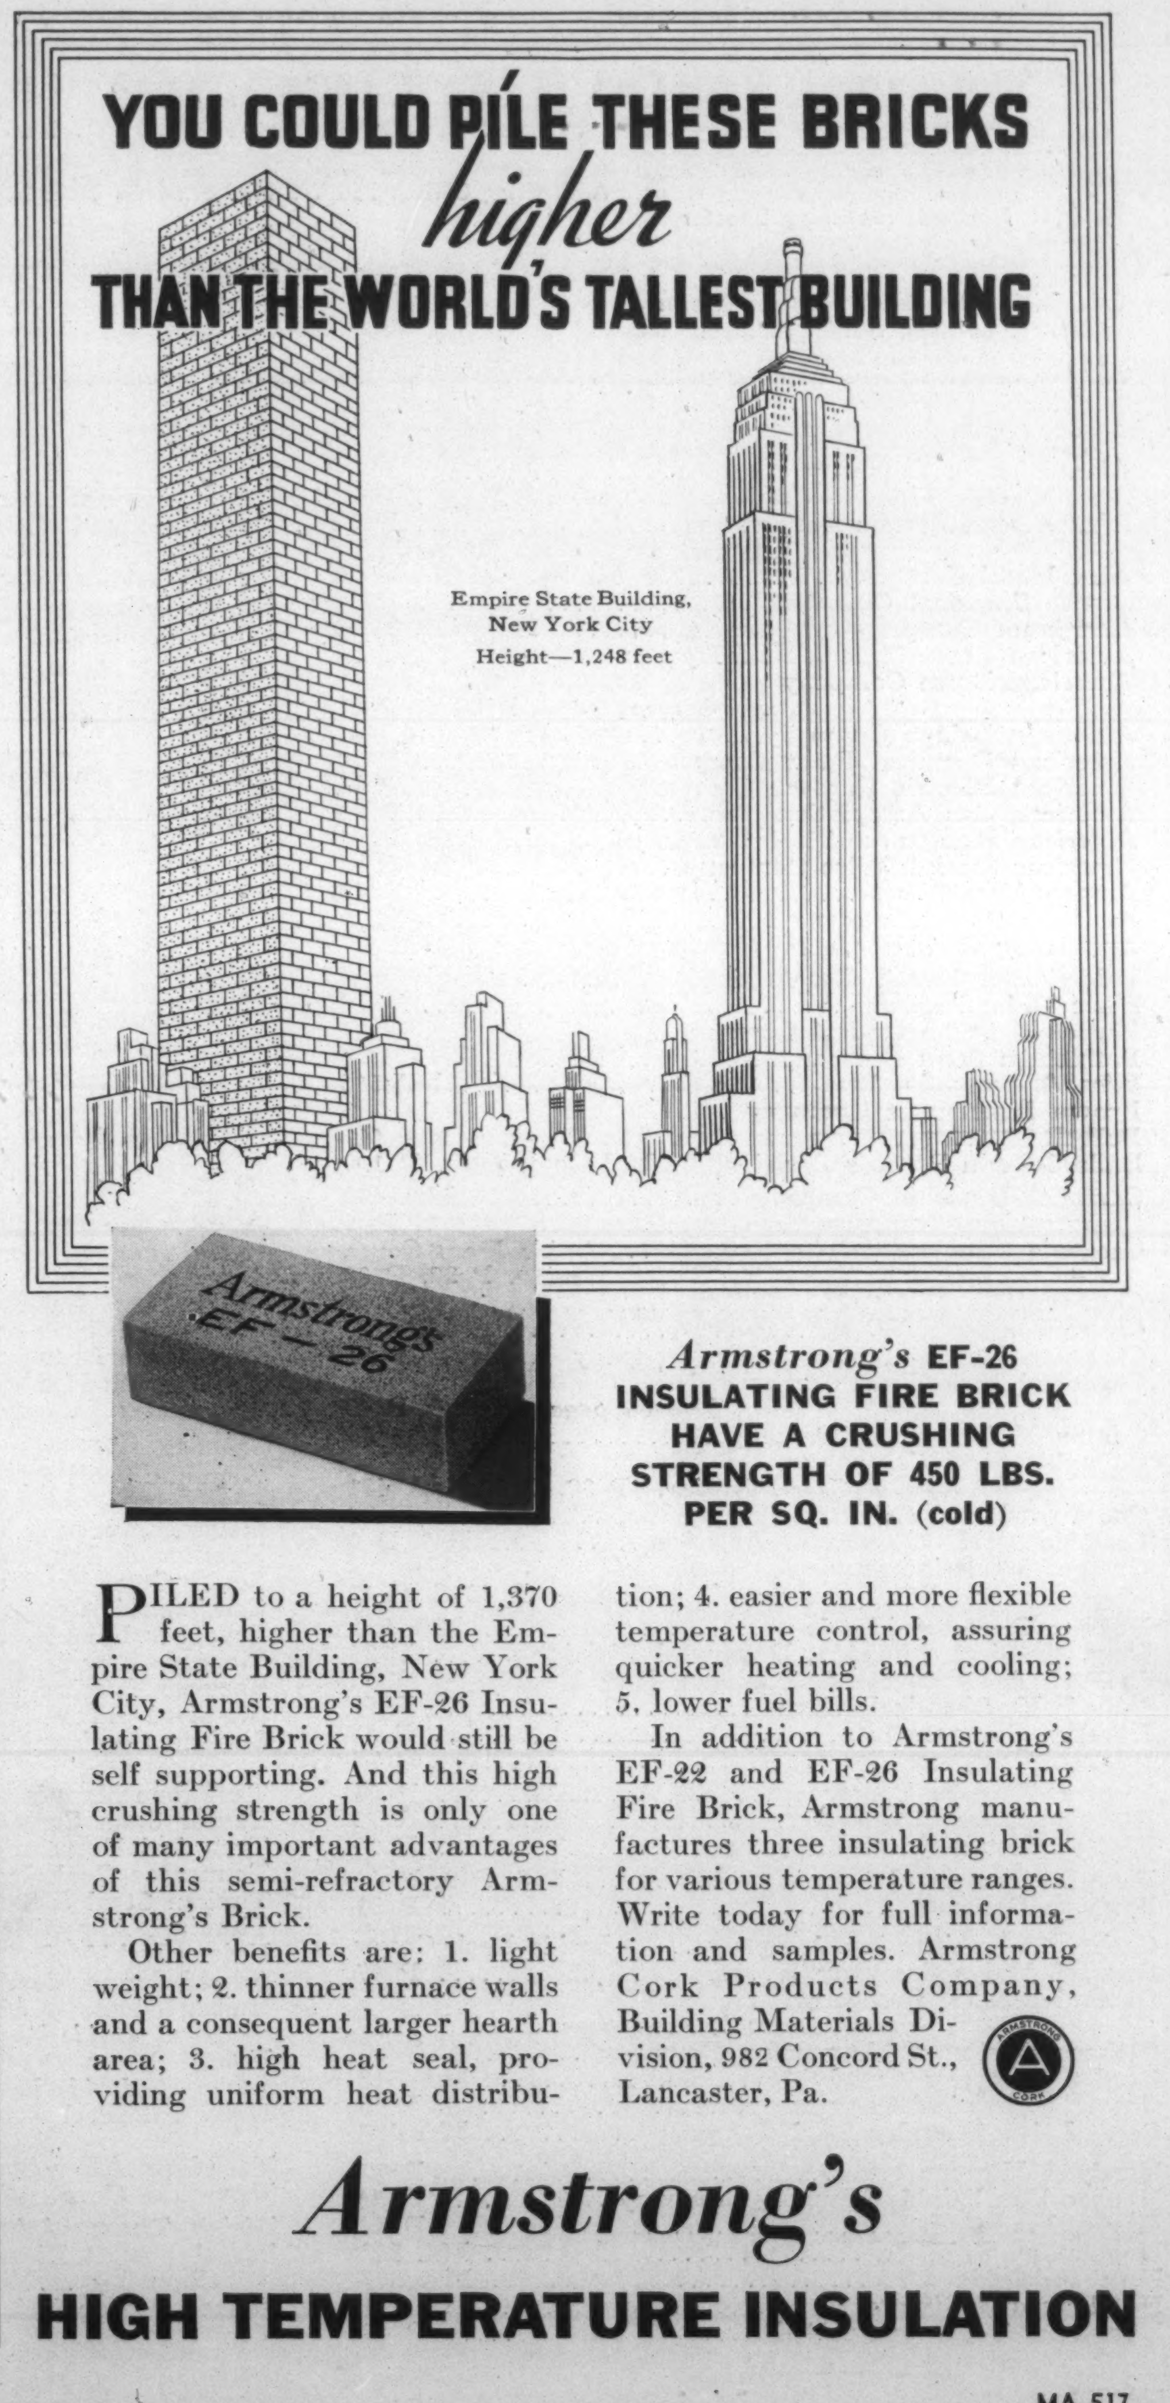
Oil Immersed Float Switch

Designed for indoors and out in corrosive or hazardous areas, the new "Rowan Oil Immersed Float Switch" adequately answers the recognized need for such a switch on sump pumps, tanks, etc., in coke plants, blast furnaces and steel mills.

Ruggedly constructed to withstand hard usage, all operating parts readily accessible for inspection, positive action, completely oil immersed, this new Rowan float switch is claimed to provide the ideal answer to the float switch problem.



Armstrong's **EF-26 INSULATING FIRE BRICK HAVE A CRUSHING STRENGTH OF 450 LBS. PER SQ. IN. (cold)**

PILED to a height of 1,370 feet, higher than the Empire State Building, New York City, Armstrong's EF-26 Insulating Fire Brick would still be self supporting. And this high crushing strength is only one of many important advantages of this semi-refractory Armstrong's Brick.

Other benefits are: 1. light weight; 2. thinner furnace walls and a consequent larger hearth area; 3. high heat seal, providing uniform heat distribution; 4. easier and more flexible temperature control, assuring quicker heating and cooling; 5. lower fuel bills.

In addition to Armstrong's EF-22 and EF-26 Insulating Fire Brick, Armstrong manufactures three insulating brick for various temperature ranges. Write today for full information and samples. Armstrong Cork Products Company, Building Materials Division, 982 Concord St., Lancaster, Pa.

JOHN ATTWOOD, SECTION EDITOR

Thirty Years of Canadian Mining. The Newer Gold Fields—I. R. C. Rowe. *Compressed Air Magazine,* Vol. 41, Jan. 1936, pages 4935-4940. Historical review of incidents and personalities in the development of the present Canadian gold mines, especially in Western Ontario and Northern Manitoba. FPP (1)

The Metalliferous Altai of Soviet Russia. I. Geology. Andrew Meyer & Edith Meyer. *Engineering & Mining Journal,* Vol. 137, June 1936, pages 275-278. Geological exploration of deposits along two tactonic zones discloses mineralization of unusual extent. A brief history and geology of the Altai mining region and a description of the mining, milling, and metallurgical practices of today. Ag, Au, Cu, Sn, and Pb have been procured from these mines. WHB (1)

The Gold Mining Industry of Western Australia. B. H. Moore. *Journal Institution of Engineers, Australia,* Vol. 8, Apr. 1936, pages 154-156. An abstract. A brief general survey of the geological conditions obtaining in the auriferous areas, the nature of the ores themselves and a general description of the methods adopted for extracting the Au from these ores. WHB (1)

Gold Mining in the Philippines. Ralph Keeler. *Compressed Air Magazine,* Vol. 41, Mar. 1936, pages 4978-4983. In 1935, 15 million dollars worth of Philippine Au was mined. Historical, economic and geographical considerations are discussed. At present there is one leaching plant in the Baguio district and several cyanidation-flotation mines. FPP (1)

Gold and Molybdenum from Rehabilitated Mines in Mammoth, Arizona. J. B. Huttl. *Engineering & Mining Journal,* Vol. 137, June 1936, pages 286-287. Descriptive. WHB (1)

Concentration of Copper-Iron Ores of Kiyalykh-Usenj District. O. A. Deminova. *Tzvetnuie Metallui,* June 1935, pages 18-36. In Russian. Describes results of concentration tests of the Cu-Fe ores of Kiyalykh-Usenz (Western Siberia). BND (1)

Weepah Gold—Modern Methods and Equipment Make Possible the Operation of an Idle Mine. T. H. Oxnam. *Engineering & Mining Journal,* Vol. 136, June 1936, pages 300-303, 306. The Au in this ore is largely in the free state, with a little Ag in a silicified gangue composed of quartz and altered country rock. The flowsheets for amalgamation and for flotation are shown. WHB (1)

Some Developments in Ore Pulp Classification. D. MacLean & C. L. Dewar. *Journal Chemical, Metallurgical & Mining Society South Africa,* Vol. 36, Feb. 1936, pages 215-216. Discussion. See *Metals & Alloys,* Vol. 6, Dec. 1935, page MA 479L/9. AHE (1)

■ 1a. Crushing, Grinding & Plant Handling ■

Recent Developments at Bendigo—Favorable Results on Nell Gwynne and Deborah Lines. A. J. Moore. *Chemical Engineering & Mining Review,* Vol. 28, July 8, 1936, pages 351-354. The most important developments in Bendigo this year have been the uncovering of 2 saddle-reefs at the Monument and the reefs at the Central Nell Gwynne Syncline. Up to the beginning of this year the unsatisfactory results during the recent revival have been practically all from other types of reef. WHB (1a)

■ 1c. Flotation ■

Flotation—Application to Non-Metallics. Arthur F. Taggart. *Engineering & Mining Journal,* Vol. 137, Feb. 1936, pages 90-91. Separation of oxidized minerals by differential air levitation with oil has interesting and important commercial and industrial possibilities. WHB (1c)

1e. Amalgamation, Cyanidation & Leaching

The Precious Metals—Problems in Their Recovery. John H. Clevenger. *Engineering & Mining Journal,* Vol. 136, Feb. 1936, pages 87-89. Some difficulties are still unsurmounted in cyanidation, despite development of methods to treat refractory ores. WHB (1e)

The Addition of Lead Salts in Cyaniding Gold Ores. F. G. Macdonald & H. R. Adams. *Journal Chemical Metallurgical & Mining Society South Africa,* Vol. 36, Feb. 1936, pages 216-217. Discussion. See *Metals & Alloys,* Vol. 6, Nov. 1935, page MA 434R/5. AHE (1e)

Itogon—A Philippine Gold Producer. Ralph Keeler. *Engineering & Mining Journal,* Vol. 137, Jan. 1936, pages 3-8. An illustrated description of the mining operations at the Itogon Mining Co. where 10,000 tons of ore per month are treated by all-sliming, countercurrent cyanidation with close to 92% recovery. A flowsheet and numerous illustrations are included. WHB (1e)

2. ORE REDUCTION

A. H. EMERY, SECTION EDITOR

■ 2a. Non-Ferrous ■

Ductile Chromium (Das duktile Chrom) W. Kroll. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 226, Dec. 31, 1935, pages 23-32. Examples of ductile Cr prepared by various methods are given. When 99% Cr prepared by the thermit process is distilled under high vacuum, part of the distillate is hot-forgeable to a small extent. Electrolytic Cr when heated to 1300° C. in high vacuum can be deformed and bent at dark red heat. The same metal if distilled in BeO crucible under high vacuum and remelted in A atmosphere is hot-forgeable. Cr cannot be melted under high vacuum for it sublimates before reaching its m.p.: it must be melted in A at a greater pressure. Sheets of electrolytic Cr cannot be rolled after degassing because (1) the shrinkage in volume due to escape of H_2 is coupled with tear formation, and (2) it contains too many oxide inclusions. The direct reduction of $CrCl_3$ and Cr_2O_3 with Ca in a steel bomb is described. $CrCl_3$ is obtained by chlorinating Fe-Cr, chromite or Cr and is sublimated for purification; it is only slightly hygroscopic. Ca rather than Mg or Na is preferred for reduction because of its lower b.p. The Ca was distilled twice in high vacuum. The bomb is lined with $CaCl_2$: the charge of $CrCl_3$ and 20 excess Ca is heated in high frequency furnace to 500° C., at which temperature ignition starts. The reduced Cr melts and forms pellets which can be hammered hot. Cr_2O_3 reduced with 20% excess Ca gave somewhat larger pellets with same properties but both Cr products are not commercial since they cannot be briquetted and worked to uniform rolled products. A powdered Cr of briquetable form is obtained by Marden process of Ca reduction with closed bomb in $CaCl_2$ melt, but Kroll finds a $BaCl_2$-$CaCl_2$ melt for reducing Cr_2O_3 with Ca more suitable. The process is possible in open crucible heated in high frequency furnace in A atmosphere. The product is washed with water and HCl and subjected to a second reduction to eliminate residual oxide. It can be pressed and degassed at 1300° C. in high vacuum and sintered under low A pressure at 1600°-1700° C. The product is forgeable at 1250° C. when heated in $BaCl_2$-$CaCl_2$ melt and is brittle at room temperature. K. concludes that the product will have little use because of its easy solubility in most acids. WB (2a)

Production of Low-Silica Alumina at the Volkhov Alumina Plant. M. M. Loboda. *Legkie Metallui,* Vol. 5, Jan. 1936, pages 5-10. In Russian. This plant uses bauxite containing 10-15% SiO_2. The aluminate solution, which contains about 120 g. Al_2O_3/l., is desiliconized at 150° by adding 8-10 g./l. CaO. An Al_2O_3:SiO_2 ratio of about 600-700 is obtained. HWR (2a)

The Production of Alumina at the Dnieper Aluminum Plant. V. A. Mazel. *Legkie Metallui,* Vol. 5, Mar. 1936, pages 1-15; Apr. 1936, pages 1-12. In Russian. A Ca aluminate slag is produced by fusing bauxite with coke and limestone in an electric furnace. The Al_2O_3 is extracted by digesting the crushed slag in an Na_2CO_3 solution. The recovery of Al_2O_3 depends more on the mineralogical composition of the slag than on its chemical composition. Recoveries of over 85% are obtained from all slags in the $CaO.Al_2O_3$ field if they are cooled slowly. HWR (2a)

Electrolysis of Alumina with Metallic Anodes. A. I. Belyaev & Ya. E. Studentzov. *Legkie Metallui,* Vol. 5, Mar. 1936, pages 15-24. In Russian. Anodes of Cu and of Fe plated with Ni, Cr, and Ag were used to electrolyze Al_2O_3 at 935° in an electrolyte composed of equimolecular mixture of K_3AlF_6 and Na_3AlF_6 to permit the use of a low temperature. Electrolysis proceeded satisfactorily but the anodes were rapidly destroyed. HWR (2a)

Action of Gaseous Chlorine on Sulphides, Oxides and Sulphates of Lead, Zinc, Copper, Silver and Iron in Relation to Temperature. D. M. Chizhikov & G. S. Balikhina. *Tzvetnuie Metallui,* May 1935, pages 59-77. (In Russian). The effect of gaseous Cl on sulphides (PbS, ZnS, Cu_2S, Ag_2S, Fe_2S), oxides (PbO, ZnO, CuO) and sulphates ($PbSO_4$, $ZnSO_4$, $CuSO_4$), at temperatures from 100° to 800° C. was studied. Conclusions: The sulphides of Pb, Zn and Cu are the easiest to convert into chlorides and the sulphates the most difficult. The chlorination of sulphides and oxides is easily completed at temperatures up to 700°, while the chlorination of sulphates below this temperature proceeds only very slowly. As a rule the chlorination of sulphides begins at lower temperatures than that of oxides and sulphates. With increasing temperatures the velocities of chlorination of sulphides and oxides tend to equalize. BND (2a)

Nepheline and Alunite as Raw Materials for the Aluminum Industry. M. S. Goluinskii. *Legkie Metallui,* Vol. 5, Jan. 1936, pages 37-44. In Russian. The Kandalakshe Alumina Plant, under construction in Karelia, will use nephelite. This is impractical because of high cost of fuel and limestone in that district. The possibility of using alunite in the Caucasus is discussed. $(NH_4)_2SO_4$, obtained as a by product, could be disposed of as a fertilizer. HWR (2a)

Running Miguet Furnaces. Ya. Schedrovitzki. *Metallurg,* No. 3, 1936, pages 67-76. In Russian. Information available is not sufficient to justify adding components of charge separately in preference to charging them as a mixture. Rules applicable to cost of a furnace become invalid when the same furnace is used on a different process. (2a)

2b. Ferrous

Study of Decomposition and Reduction of Siderite from Bakal Deposits. M. M. Leibovich. *Metallurg,* No. 2, 1936, pages 78-88. In Russian. Decomposition and reduction of siderite was investigated using a stream of H in an electric tube furnace. Decomposition of Ca and Mg carbonates goes simultaneously with Fe, starting at 400° C. and is practically completed at 500° C. Reduction of Fe begins ahead of carbonate decomposition. Retarded heat transfer into the interior of 1″ lumps used for the investigation shifted the temperature for complete decomposition about 100° C. upwards. Reduction of roasted siderite began at 300° C., the reaction proceeding more energetically than in raw siderite in the interval 300°-600° C., after which raw siderite is more active. At 800″ C., total reducibility of Bakal siderite ores is but slightly inferior to brown Fe ores from the same locality. (2b)

Thermodynamic Study of Phosphorus Behavior under Conditions Existing in Blast Furnace Working on High Alumina Slags. V. V. Mikhailov. *Metallurg,* No. 2, 1936, pages 72-78. In Russian. Purely theoretical calculations. $(FeO)_3P_2O_5$ is reduced by solid C beginning at 900°-950° C. In blast furnace practice when ordinary slags are used direct reduction of P begins at 1280° C.; for high alumina slags it is 1380° C. Presence of reduced Fe helps P reduction. Under normal conditions of blast furnace operation no reduction of P can be expected. (2b)

Phosphorus Reduction During Reduction of Iron Ores. A. P. Lyuban. *Metallurg,* No. 2, 1936, pages 54-72. Ca phosphate, apatite, Fe phosphate and Ag phosphates were investigated. Heating in air or N up to 1530° C. does not decompose Fe phosphates. In a stream of H reduction of Fe phosphates to Fe phosphides begins at 400° C.; reduction is practically completed in 20-30 minutes at 1200°-1300° C. Reduction with CO was considerably slower than with H_2 at temperatures below 1100° C.; above this, the speed was practically the same. Neither $Ca_3(PO_4)_2$ nor apatite react with SiO_2 and Al_2O_3 when heated in air or N up to 1470° C. Reduction by charcoal begins a little below 1000° C., apatite being more resistant than phosphate. Admixture of SiO_2 and Al_2O_3 with phosphate-charcoal mixture somewhat increases reduction. Amorphous SiO_2 and Al_2O_3 act more positively than crystalline. An atmosphere of CO and H_2 reduces Ca phosphate appreciably. At 1000° C. Ag phosphate begins to decompose in air, though only P_2O_5 is evolved. Reduction of $Ca_3(PO_4)_2$ dissolved in 45% Al_2O_3-55% CaO and 45% SiO_2-55% Ca slag kept in a crucible over Fe at 1500°-1550° C. is quite rapid, so that replacement of SiO_2 with Al_2O_3 does not have any effect on the rate of reduction observed in 10 minutes. Decomposition of phosphates can be effected in an atmosphere in which partial pressure of O is continuously reduced below a certain limit. For each temperature a definite partial pressure of P_2O_5 which is very low but has a pronounced action on reduction is established around specimens. Lowering it by reducing atmosphere accomplished the reaction. (2b)

Some Observations on Operation of a Ferro-Manganese Furnace (Quelques observations sur la marche d'un four à ferro-manganèse) Maurice Dériběré. *Journal du Four Electrique,* Vol. 45, June 1936, page 204. A sketch of conditions occurring in the hearth of such furnaces. JDG (2b)

Quality of a Casting. Casting of Natural Alloys and the Blending of Different Kinds of Cast Iron (Le Problème de la Qualité du Moulage. Le Moulage d'Alliages naturels et le Croisement des différentes Espèces de Fontes) S. S. Nekryty. *Revue de Fonderie Moderne,* Vol. 30, Mar. 25, 1936, pages 91-95. The production of special cast irons directly in the blast furnace is discusseed with particular regard to the considerable quantities of Russian Fe ores containing deoxidizing elements (Ti, V) or anticorrosive elements (Cr, Ni, Co, Cu), besides the usual elements. The possibilities of mixing different ores to obtain a desired result is discussed; with rational selection of ores, cast Fe of any desired quality can be produced directly from the ores in the blast furnace. Ha (2b)

Effect of the Nature and Efficiency of the Charge on Coke Consumption in Blast Furnaces (Influence de la Nature et du Rendement du Lit de Fusion sur la Consommation de Coke, dans les Hauts-Fourneaux) J. Lilot. *Revue Universelle des Mines,* Vol. 12, June 1936, pages 236-241. A formula is developed which connects the amount of coke required to the efficiency of the charge; the derivation of the constants in the formula is explained. If M is the amount of coke consumed per ton of cast Fe, and R the efficiency in % of the charge, then $M = 307.5 + 21{,}505/R$; R is determined as ratio of the weight of coke in per cent of the charge in minerals. For different minerals or ores the formulas are:

$M = 238 + 34{,}700/R$, for minerals with Fe in the form Fe_2O_3
$M = 339.5 + 21{,}505/R$, for minerals with Fe in the form Fe_3O_4
$M = 237 + 21{,}505/R$, for minerals with Fe in the form FeO
$M = -972 + 125.3/R$, for oxidized scrap.
$M = 65 + 14{,}385/R$ for non-oxidized scrap containing foreign matter.

A correction is given to take care of varying amounts of water and ash in the coke. The way to determine the thermal efficiency of the blast furnace is explained. Examples illustrate the application of the formulas. Ha (2b)

Hot Blast Temperature Is Controlled Automatically. G. P. Lonergan. *Steel,* Vol. 98, Mar. 30, 1936, pages 66, 68. Temperature of hot blast admitted to blast furnaces can be maintained as closely as ± 4° F. with automatic control equipment. Some benefits are smoother furnace operation; positive means of maintaining constant quality Fe, other conditions being equal; elimination of constant manual supervision; and reduction of strains and stresses set up in blow-pipes, tuyere stocks, and bristle-pipe lining as a result of fluctuating temperature. Temperature regulation is accomplished by automatic manipulation of the regular mixing-valve in the by-pass between cold-blast and hot-blast mains. Apparatus includes an electrical valve operator, a controlling pyrometer, a group of adjustable interrupters, magnetic contactors, and a manual control station for putting valve under hand control at any time. There is also a "fast opening attachment" whereby at time of stove changes, mixing-valve may be run open at full speed without waiting for controller to take command. Performance of the apparatus is outlined. MS (2b)

3. MELTING, REFINING AND CASTING

Production of Griffin Wheels at Uralsk Car Factory. P. N. Aksenov & S. E. Rosenfeld. *Liteinoe Delo,* Vol. 7, No. 4, 1936, pages 12-22. In Russian. During the first 8 months of production (1934) 18,000 (sic) wheels were cast of which 82 were passed by inspectors. Quality of production is improved somewhat at the present and the measures leading to it are described. (3)

Strickle Moulding of Large Castings. H. Fabre & H. Dubois. *Proceedings Institute of British Foundrymen,* Vol. 28, 1934-1935, pages 249-274. See *Metals & Alloys,* Vol. 6, Dec. 1935, page MA 482. CEJ (3)

Oven-Drying of Cores and Molds. E. G. Fiegehen. *Proceedings Institute of British Foundrymen,* Vol. 27, 1933-1934, pages 169-183. See *Metals & Alloys,* Vol. 6, June 1935, page MA 222, and Vol. 5, Dec. 1934, page MA 557. CEJ (3)

The Sand Preparation Plant. G. E. France. *Iron & Steel Industry,* Vol. 9, Oct. 1935, pages 17-20. The aim of the modern sand preparation plant is to prepare a reliable and satisfactory molding sand at a minimum cost. A modern sand preparation plant is described consisting of one sand mixing mill which handles approximately 4,000 tons of facing sand per year. The labor saving is 60%; the sand consumption is reduced by approximately 1/3. CEJ (3)

Slag Control. W. Ash. *Iron & Steel Industry,* Vol. 9, Feb. 1936, pages 175-176. The functions of slag in the refining of steel are: (1) absorption and retention of the impurities of the charge, (2) control of the oxide content of the metal, (3) protection of the liquid metal from contact with the flame. These 3 functions of slag are common to both the acid and basic open-hearth processes. The manufacture of high quality steel by any process is a matter of oxide control. Acid and basic methods of control are discussed. CEJ (3)

Castings. W. Machin & M. C. Oldham. *Proceedings Institute of British Foundrymen,* Vol. 28, 1934-1935, pages 361-481. See *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 52L/4. CEJ (3)

Present State of Die Casting (La Fonderie sous Pression: Etat actuel). Paul Bastien. *Bulletin de l'Association Technique de Fonderie,* Vol. 10, Apr. 1936, pages 114-120. German Progress in Piston Rings, Brake Drums and Other Automobile Castings. W. A. Geisler. *Proceedings Institute of British Foundrymen,* Vol. 28, 1934-1935, pages 282-310. Standard piston rings which are not subjected to excessive stresses can be produced most advantageously by the single-ring process. For alloyed piston-rings subjected to high stresses such as those for use in Diesel engines and airplane engines, the centrifugal casting process appears to be better suited. For brake drums cast Fe is far superior to all other materials. In order to secure sufficient strength with lightness of construction a combination Fe and steel drum is used, the "Centrifuse" and "Centrit" brake drums being of this type. See also *Metals & Alloys,* Vol. 7, Feb. 1936, page MA 52L1. CEJ (3)

Products of the Foundries. Vincent C. Faulkner. *Times [London] Trade & Engineering,* Vol. 38, Dec. 1935, pages XII. Discusses foundries of the West Midlands district of England. Repairing Porous Non-Ferrous Castings by Impregnation with Bakelite Varnish. Z. I. Shneiderman. *Liteinoe Delo,* Vol. 7, No. 4, 1936, pages 25-26. In Russian. To prevent sweating of porous bronze castings, the castings were impregnated with bakelite varnish under pressure of 3.5 atmospheres, dried for 2 days at room temperature and baked 2 hours at 200° C. Castings so treated were able to withstand a hydraulic pressure of 15 atmospheres and a live steam pressure of 20 atmospheres. (3)

The Possibilities of the Electric Furnace in the Cast-Iron and Brass Foundry. A. G. Robiette. *Foundry Trade Journal,* Vol. 54, Feb. 27, 1936, pages 173-177. A paper read before the London branch Institute of British Foundrymen. It is now nearly 20 years since Elliott demonstrated by duplexing cupola metal in a basic-arc furnace, that it was possible to obtain a vastly superior product from the point of view of strength and density, by a simple refining operation. In America, and to a lesser extent in Germany, the development of the electric furnace for this purpose grew, especially with a fuller knowledge of the effects of superheating upon graphite formation, with the increasing use of expensive alloying elements, and with the realization that cheap light scrap could be utilized as one of the basic raw materials. Types of furnaces employed, melting practice, Rocking arc furnaces, semi-continuous operation, advantages of electric melting, application on the jobbing foundry, electric furnace in the mass-production foundry, electric furnace for malleable production, application of the electric furnace in the brass foundry, etc., are discussed by the author. Pig is rarely used in large proportion since one of the advantages of the electric furnace is that it can utilize cheap scrap, even borings and steel turnings, thus rendering the process economical even for irons which do not strictly come within the classification of high-duty or special irons. AIK (3)

Investigation of Parting Compounds (Beitrag zur Untersuchung von Formpuder) F. Roll. *Giesserei,* Vol. 23, May 8, 1936, pages 236-238. The properties required of a good powder to prevent the sticking of molding sand to the pattern are discussed. Vegetable powders (lycopodium), and the more generally used kieselguhr, calcium carbide, fireclay, metal oxides, were investigated; the results as to chemical composition, color, melting point, and behavior are tabulated. G. L. CRAIG, SECTION EDITOR

Recommendations for Two Leaded Gunmetals. By the Non-Ferrous Sub-Committee of the Institute of British Foundrymen. *Metal Industry,* London, Vol. 48, June 12, 1936, pages 660-662, 664. This technical report was presented at the Glasgow Conference of the Institute and aims at the standardization of a few suitable compositions of leaded gunmetals. A lack of standard specifications has made it necessary for foundries to make gunmetal to conform to the desires of individual customers when the desired alloy differs from "Admiralty" gunmetal. For the latter, the British Standards Institution have drawn up the specification B.S.I. No. 383/1930. In a preliminary survey conducted by the Sub-Committee 37 specifications were found to be in use, the major constituents of which were within the ranges of Cu 82-93%, Sn 4-9%, Pb 0-7%, and Zn 1-8%. The Sub-Committee believes that it would be to the advantage of both producer and consumer if a few compositions were to be accepted as standard which would adequately cover the field now represented by the 37 specifications. In the survey wide variations in physical test data were found which was attributed to differences in (1) types of test bars, (2) shapes of bars, (3) methods of casting, and (4) character of the molds. It is recognized that test bars at best can give only an indication of the quality of the metal and are not truly indicative of the properties of the castings. Factors considered in the selection of the type of test bar recommended by the Sub-Committee were uniformity of results obtainable and simplicity in production. The bar recommended by the sub-Committee is made in 2 sizes, dimensioned drawings and photographs of which are included in the article. The sub-Committee recommended 2 alloys to cover the field of the 37 specifications previously mentioned. The compositions of these alloys are

	Copper %	Tin % Min.	Zinc % Max.	Lead % Max.
87:9:3:1 Gunmetal	Remainder	8	4	2
85:5:5:5 Gunmetal	Remainder	5	6	6

7 bronze foundries made series of test bars of these alloys using green sand, dry sand or both with the recommended types of test bars, casting at 1200°, 1150°, and 1100° C. The data obtained are reported for maximum stress, elongation, Brinell hardness and density for both sizes of test bars, using both dry and green sand. HBG (3a)

Lining of Bearings (Das Ausgiessen von Lagern) E. Meier. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, May 23, 1936, pages 652-654. Report of the Committee on Bearing Materials is reviewed. Possibility of replacing the imported Sn in bearing metals by domestic (German) Pb and preparation of the bearing and methods of casting the metal into the bearing bushing (to line it) with Pb alloys are described. The lining should be cooled as quickly as possible; casting should be done at 420°-540° C. The mold should be heated to 150° to 200° C. Methods for centrifugal and die casting of bushings are described. Ha (3a)

Influence of Remelting on Structure and Mechanical Properties of Stellite. I. S. Brokhin & C. Ya. Ar'eva. *Metallurg,* No. 3, 1936, pages 89-94. Stellite scrap was melted in magnesite lined crucibles and deoxidized with 0.3% of Mn and of FeSi. To take care of oxidation, 1-2% Cr, 1-2% of 80% FeW and 0.5-0.75% of 70% Fe-V were added under slag. Cast in Cu or cast Fe chills 20 x 20 mm. at 1425°-1450° C. the metal produced had the same composition as scrap and the same physical and cutting characteristics. (3a)

Phenomena in the Melting of Bronze (De Quelques Petits Phénomènes que Accompagnent la Fusion du Bronze) C. Dennery. *Bulletin de l'Association Technique de Fonderie,* Vol. 10, Mar. 1936, pages 78-89. Paper presented before the A. T. F., Mar. 17, 1936. During melting in crucible or hearth furnaces, the bronze is exposed to air and to the products of combustion, either complete or incomplete. In the electric furnace and reverberatory furnace with precombustion chamber the exposure is more limited. The gas content of the molten metal is dependent on the amounts of the gaseous elements present in the furnace, section size of the unmelted metal, the length of the heat, atmospheric moisture, surface condition of the raw material, circulation velocity of combustion gases, and pressure inside the furnace. Effects of H_2, O_2, $H_2 + O_2$, CO and CO_2 are discussed. Different reducing agents and physical or mechanical purification of the metal are considered at length. WHS (3a)

Ford's New Facilities for Casting Alloy Steels. *Iron Age*, Vol. 137, Apr. 30, 1936, pages 2-25. Describes new plant for casting of crankshaft and camshaft which were formerly forged at the plant of Ford Motor Co. The new electric furnaces are of top-charge type. All operations of furnace are protected by sequence movement interlocks. A number of vertical continuous core ovens have been installed for baking cores and paste drying. Several types of alloy cast steel parts are also made in this foundry. Gives analysis of steels used. VSP (3b)

Production of Steel Castings. *Foundry Trade Journal*, Vol. 54, Feb. 20, 1936, pages 155, 160. The principal factors in production of steel castings such as shrinkage and application of chills are considered. It is pointed out that experiments by Benedicks and calculations made by Honda show that steel passing from the liquid to solid phase contracts about 5.5% of its volume. According to T. M. Service solid steel weighs 490 lbs./ft.^{3}, whereas liquid steel weighs only 437 lbs./ft.^{3} which is equal to a change in specific gravity of from 7.85 to 7.00. Therefore, to obtain 1 ft.^{3} of solid steel 1.12 ft.^{3} of fluid steel will be required, or a total shrinkage of 10.72% takes place from 1500° C. to room temperature. The simplest form of steel casting is the tapered ingot, cast wide-end up. As far as possible, a steel casting should be made with the heavier sections above the light ones. Where it is not practicable to feed isolated heavy sections from risers, chills are applied. Because of the difficulty of estimating the amount of chilling required, the use of chills is always a very uncertain measure, and there is always a possibility of causing cracks, one of the particular defects chills are used to eliminate. AIK (3b)

The Whifflet Foundry of R. B. Tennent, Limited. *Foundry Trade Journal*, Vol. 54, Feb. 20, 1936, pages 153, 154. The present output of the works covers the complete range of roll requirements, including cast Fe grain rolls, cast Fe chilled rolls, steel rolls of all qualities, and Pilger rolls for tube mills. The melting plant comprises 4 reverberatory furnaces of melting capacities ranging from 25 to 35 tons. The furnaces are coal fired. The question of firing with pulverized fuel was carefully considered, but was rejected as an unsound commercial proposition with Scottish coals. The 3-ton cupolas are installed, and are blown by Roots blowers. There is also a 50-ton open-hearth furnace. It has a removable roof which enables heavy scrap, sometimes in sizes up to 15 tons, to be charged direct on to the hearth. At the present time Whifflet foundry has an arrangement with the Macintosh-Hemphill company of the United States for the manufacture of "Adamite" rolls. Broadly speaking, the "Adamite" alloy is made in 2 forms, i.e., as a steel base and as a cast Fe base alloy. The steel-base "Adamite" rolls have the whole of the C content in the combined form, with a sceleroscope hardness number ranging from 32 to 55, this hardness being substantially constant throughout the mass. In all cases (steel or cast Fe base) the alloys have the same low P content, and have Cr and Ni as the main alloying elements. They differ in regard to Si and C content, and, in the steel-base varieties, as regards their melting and subsequent heat-treatment. There is a decidedly important difference structurally between the "Adamite" Fe base alloy chilled roll and the ordinary chilled cast Fe roll. In the first-named there is no noticeable line of demarkation between the hard outer surface and the body of the metal, from which it is evident that the diminution of hardness is very gradual, thus adding to the wear-resisting qualities of the roll. It is claimed that the "Adamite" chilled roll, despite its hard internal structure, is at least 30% stronger than ordinary cast Fe chilled rolls. AIK (3b)

Auto Pistons Cast Horizontally. *Foundry*, Vol. 64, Apr. 1936, pages 50-51, 98, 103. Describes equipment and method used in producing alloy steel, light weight pistons for Lincoln-Zephyr car by the Ford Motor Co. Pistons are poured in horizontal position in all green sand molds. Green sand for securing a fine degree of accuracy is rammed harder than usual for green sand practice. Metal used has composition: C 1.35-1.70%; Si 0.90-1.30%; S 0.08% max.; P 0.10% max.; Mn 0.60-1.00%; Cu 2.50-3.00%; Cr 0.15-0.20%. VSP (3b)

Metal Moulds for Cast Iron. J. McGrandle. *Foundry Trade Journal*, Vol. 54, Jan. 16, 1936, pages 74-76. A paper read before the Scottish branch of the Institute of British Foundrymen. The castings here dealt with, cast in cast Fe molds, are all of one type, all being air turbine rotors. The castings for these rotors vary in weight from 23 to 290 lbs. as cast. There are 6 different sizes, all in the form of hollow cylinders. The thickness of section of the castings varies from 1½″ in the smallest size casting to 4½″ in the largest size, the outside diameters of the smallest and largest being 5½″ and 13½″ respectively, and the inside bores from 2½″ to 4½″. The castings made in cast Fe molds are run from the ordinary 2% Si metal. The molds are made from an ordinary 2% Si Fe of the following approximate analysis:—Tot. C, 3.5-3.6; Mn, 0.6-0.8; S, 0.05-0.06, and P 0.4-0.6%. This analysis is also used for the rotor castings. Metal mold design, life of molds, coatings of molds, soundness of castings, microstructure, etc., are discussed by the author. The large recessed mold has shortest life, averaging from 90 to 100 coatings per mold. In the medium size, that is, those having a mold thickness of 2½″, a thickness of casting of 2⅞″ and the centre diameter of 3″, about 250 to 350 castings are made before mold is scrapped. At the present time a thin ordinary blackwash coating is used which, whether necessary or not, is removed, and the mold is recoated each day. From the point of view of cavities of any description the soundness is practically 100% perfect. AIK (3b)

Equilibrium of Dissolved Carbon in Liquid Iron and a Gas Containing CO or CO_2 (Om jämvikten mellan kol, löst i smält järn, och en gas, innehållande koloxid och koldioxid) G. Phragmen. *Jernkontorets Annaler*, Vol. 120, Apr. 1936, pages 184-189. Author concludes that the thermodynamic activity of C is lower than that calculated on the assumption that it is proportional to the molar concentration. HCD (3b)

Study of Viscosity of Production Blast Furnace Slags. N. V. Rulla. *Domez*, No. 10, 1935, pages 18-27. In Russian. Detailed description of an improved McCaffery viscosimeter (see "Research on Blast Furnace Slags," *Metals & Alloys*, Vol. 2, Apr. 1931, page 91) sensitive to less than one poise. Theoretical consideration on which the operation of similar viscosimeters is based and their calibration is given. Operating procedure used in operation with blast furnace and synthetic slags is described. Data obtained and conclusions are left for a subsequent publication. 31 references. (3b)

Open Hearth Furnace Operation, Four Million B.t.u. per Ton. E. H. Schwartz. *Iron & Steel Engineer*, Vol. 13, Jan. 1936, pages 1-8. Paper presented and discussed at A. I. & S. E. E. Convention, Pittsburgh, Sept. 1935. Describes the use of regenerated mixture of coke oven and blast furnace gases as open hearth fuel. Gas is heated to 2150° F. and air to 1850° F. A highly luminous flame results that hugs the bath making for efficient heat transfer by radiation. 4,000,000 B.t.u./ton fuel consumption bears this out. Open hearth fuel consumption is continuous as is the production of these gases which makes their use efficient. Leakage of regenerated gas is very noticeable leading to remedial measures while air infiltration is less obvious and apt to be disregarded though the attendant losses are heavy. Regenerated gas gives an efficient luminous flame right at the port; whereas other fuels do not produce a luminous flame until they reach well into the furnace. WLC (3b)

Adding Ferroalloys in the Cupola. E. K. Smith & H. C. Auferhaar. *Transactions American Foundrymen's Association*, Vol. 7, Feb. 1936, pages 313-320. The use of briquetted ferroalloys for cupola mixtures was first developed in Europe about the time of the World War. The briquets used today are made of crushed ferroalloy with a binder of suitable cement. Briquets are used extensively for high-strength or alloyed irons, or where it is desirable to increase the percentage of scrap in the charge. Several typical mixtures for various types of castings are presented. Physical properties of irons from these mixtures are listed. CEJ (3b)

Casting Gray Iron under Pressure in Metal Molds. L. M. Waite. *Iron Age*, Vol. 137, Apr. 30, 1936, pages 30-32. Describes results obtained by the Wetherill Engineering Co. in casting of gray Fe under pressure in metal molds or in sand. VSP (3b)

The Pouring of Molten Steel, Efforts Made to Produce Sound Ingots. J. D. Walters & E. G. Hill. *Iron & Steel Engineer*, Vol. 13, Feb. 1936, pages 14-18. Paper presented and discussed at A. I. & S. E. E. Convention, Pittsburgh, Sept. 1935. Discussion of various aspects of open hearth pit practice. WLC (3b)

Making Steel using Chromium Bearing Charge. N. N. Inshakov. *Domez*, No. 10, 1935, pages 28-33. In Russian. 10 heats were made in a 7 ton basic open hearth furnace using Cr bearing pig Fe in charge. The results of 2 heats are reported in detail. At the time of melting down the bath contained 1.5-2.0% Cr and 0.32% Ni. Amount of non-metallic inclusions was larger than in C heats but was within permissible limits. Distribution of inclusions was normal. Originally some $FeO.Cr_2O_3$ is formed, but all inclusions of the finished steel are composed of silicates alone. Evidence of Steinberg and Gutermann. (*Uralskaya Metallurgia*, No. 4-5, 1934, pages 34-42) regarding solubility of Cr oxides in molten steel is supported. Cr can be present in liquid steel as CrO in solution or as either Cr_2O_3 or $FeO.Cr_2O_3$ which are dispersed in it in solid state. Steel can be freed from CrO by deoxidation. At finishing temperatures when Cr content of the metal is under 0.2-0.3% dissociation pressure of CrO is greater than that of FeO so that Fe will reduce it; above 0.3% the reaction is reversed. Fe-Mn is not suitable for reduction of CrO, Fe-Si is recommended. Deoxidation cannot remove Cr_2O_3 from steel. The presence of Cr in the charge reduces the amount of its oxidation in melting. Cr_2O_3 can be removed only by vigorous boiling. (3b)

Modern Viewpoints on the Deoxidation of Open Hearth Steel (Nyare synpunkter på färskningsförloppet i martinungen) Bo Kalling. *Jernkontorets Annaler*, Vol. 120, Jan. 1936, pages 1-34. Summary of recent physico-chemical data and theories respecting the solubility of O in steel, the $C\text{-}CO\text{-}CO_2$ equilibria, the effect of Si and Mn in acid slags and their influence on the reaction of C and O, the physical conditions influencing release of gaseous products and the rate of deoxidation, and the O content in the bath during the process. 4. WORKING

4a. Rolling

RICHARD RIMBACH, SECTION EDITOR

Large Modern Rolling Mills. Their Trend (Les Grands Laminoirs Modernes. Leurs tendances) PIERRE DEVAUX. *La Revue Industrielle,* Vol. 66, Apr. 1936, pages 137-141. Stripping of ingots is now always done by a traveling crane. Progress has been made in heating furnaces as to temperature control and oxidization loss reduction. Horizontal furnaces with hydraulic cylinder pushers are more generally used. Problems met in French rolling mill plants are quite different from those encountered in America and Germany; in France rolling mills must be designed to vary the type of production according to need. Last section of the article is devoted to cold rolling of fine sheets from 5-7 mm. down to 0.25 mm. without annealing. Close grain of product is particularly suitable for Sn plating. FR (4a)

Bethlehem Opens New $20,000,000 Continuous Mill at Lackawanna. *Iron Age,* Vol. 138, July 2, 1936, pages 24-29, 90. Describes the new continuous strip sheet and plate mill of Bethlehem Steel Co. Mill has an annual capacity of 600,000 tons of strip, sheet and light plate. Sheets of 60″ width and 0.0625″ thickness, or of 72″ width and 0.078″ thickness can be continuously hot rolled in one heating. Cold rolled strips of 0.0125 gage and heavier will be made in widths up to $23\frac{1}{16}$″ and cold rolled sheets of 30 gage and heavier in widths of from 24 to 84″. VSP (4a)

4b. Forging & Extruding

A. W. DEMMLER, SECTION EDITOR

Hot-Formed Mechanical Springs, Manufacture and Life. ARMAND H. PEYCKE & ROBERT W. CLYNE. *Metal Progress,* Vol. 29, May 1936, pages 44-49. Equipment used for the hot forming of heavy springs is described. Data are presented on merits of quenching directly and reheating for quenching. The latter method is shown to produce best results. Corrosion is a serious hazard to useful life when it takes place either in service or in storage before being put into service. WLC (4b)

Die Blocks, Their Manufacture and Treatment. B. POOL. *Iron & Steel Industry,* Vol. 9, June 1936, pages 388-390. Steels intended for the manufacture of die blocks must be of the highest quality and should be made by the acid open-hearth or electric furnace processes. The structure of the steel of the die block should be made thoroughly homogeneous by forging and upsetting the block in all directions. Small die blocks usually contain from .3-.5% C while larger die blocks in C steel contain from .60-.65% C. Ni-Cr and Ni-Cr-Mo alloy steels are used for heavier work and for longer life. CEJ (4b)

4c. Cold Working, including Shearing, Punching, Drawing & Stamping

Sheet Drawing. What it is and What it Should be (L'emboutissage, ce qu'il est, ce qu'il devrait être) PAUL BUSSON. *Science et Industrie (Mécanique),* Vol. 20, Mar.-Apr. 1936, pages 52-54. It is pointed out that methods in use are somewhat empirical and that investigations made on the plan proposed by Erich Siebel would lead to improvement in drawing and particularly in the deep drawing process. There is no special school in France for teaching the drawing process whereas there are 3 schools in Germany. FR (4c)

Shearing Strip at High Speed. H. H. TALBOT. *Iron Age,* Vol. 137, June 25, 1936, pages 69-71, 128. Describes the use of recently developed drum-type shears in cutting sheets from strip coming from rolls at speeds ranging from 150 to 2000 ft./min. Sheets are cut to an accuracy of $\frac{1}{32}$″ and in some cases to within ¼″ at practically any speed. Cutting speeds and ratios are controlled through a set of specially designed gears. Gives several examples. VSP (4c)

4d. Machining

H. W. GRAHAM, SECTION EDITOR

Grinding Stresses and Grinding Cracks in Hardened and Ground Oil-Hardening Tool Steels and Some Observations on the Nature of Ground Surfaces. J. G. MORRISON. *Steel,* Vol. 98, May 11, 1936, pages 68, 79. Abstract of paper before interchapter meeting of American Society for Metals at Pennsylvania State College, May 1-2. Experiments on 18-4-1 type high-speed steel indicate that prestressing tends to fade out if part is heated uniformly to 235° F. and quenched uniformly. With non-uniform heating, prestressing effects are accentuated in hardened tool. Cracked tools may not result but there is a tendency to crack because of unbalanced stresses due partly to prestressing. Dilute HNO_3 is recommended for ultimate inspection for cracks in ground surfaces. Grinding cracks can not be removed from hardened and ground high-speed steel, whereas grinding stresses may be removed entirely by redrawing at 1050° F. for 1 hr. MS (4d)

Drilling of Heat-treated Chromium-nickel Steel (Das Bohren von vergütetem Chrom-Nickel-Stahl) F. W. MÜLLER. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, June 27, 1936, pages 809-810. Drilling tests with hardened Cr-Ni steel have shown that such plates can be drilled economically and satisfactorily with twist drills. Hardness and toughness of the material over the length of the drill hole changed considerably. Feeding by hand was better than automatic feeding as the feed could thus be better adjusted to the varying hardness. Ha (4d)

5. HEAT TREATMENT

O. E. HARDER, SECTION EDITOR

Continuous Heat-Treatment of Steels. RICHARD SAXTON. *Sheet Metal Industries,* Vol. 10, Apr. 1936, pages 289-290. General discussion. AWM (5)

Defects in Hardened Light Metals used in Orthopedic Apparatus (Beitrag zur Kenntnis von Fehlern bei der Verarbeitung von vergüteten Leichtmetallen in der Orthopädie) A. J. STELLJES. *Aluminium,* Vol. 18, July 1936, pages 302-305. Light metals used for protheses or similar devices often show cold fractures which are due to incorrect design and to improper heat treatment. The latter should consist in annealing at 500° ± 5° C., quenching in cold water, and storing for 5 days at room temperature. Ha (5)

5a. Annealing

Stress Relief Annealing High Strength Monel Metal Plate. P. R. KOSTING. *Industrial Heating,* Vol. 3, July 1936, pages 439-442, 454. The effect of temperature and duration of annealing upon the tensile properties of high strength Monel metal was investigated. The maximum increase in yield strength was obtained in the range of 550°-600° C. irrespective of whether the plate was slightly cold rolled, or hot rolled and finished at a low temperature during manufacture. Annealing first increases and then decreases yield strengths. The effect of different sets is described at length. Ha (5a)

Heat-treating Steel Wire Rods in Coils for Bolt Stock. J. M. BROWN. *Wire & Wire Products,* Vol. 11, July 1936, pages 333, 354. Installation especially designed for a bolt manufacturing plant is described. 8 coils of 730 lbs. each are heated in a gas-fired, bell type furnace to 1400° F. and cooled under control. Ha (5a)

Strain Annealing of Non-ferrous Metals. H. M. ST. JOHN. *Sheet Metal Industries,* Vol. 10, May 1936, pages 387-388. See *Metals & Alloys,* Vol. 7, June 1936, page MA 289L/5. AWM (5a)

5b. Hardening, Quenching & Drawing

Multiple Tempering of High Speed. B. M. SUSLOV. *Metal Progress,* Vol. 29, May 1936, pages 72, 74, 88. Study of the tempering of high speed steel shows austenite-martensite transformation takes place at 400°-650° F. on cooling. Repeated tempering increases hardness, time having no effect. Increased cutting life is obtained by multiple drawing, cutter with one draw showing Rockwell C 62-64 gave 40-45 parts and one with 3 draws was C 65-67 hard and machined 80-85 parts. WLC (5b)

The Heat Treatment of Steel Rails. J. C. W. HUMFREY. *Iron & Steel Industry,* Vol. 9, Mar. 1936, pages 227-232; Apr. 1936; pages 265-267. During the present century the need for rails having not only increased strength as girders but greater resistance to wear and abrasion has been constantly increasing. 2 methods of improving the properties of rail steel are available, viz., chemically by the addition of hardening elements, or by heat treatment. Various processes for the heat treatment of rails are now in operation. The Sandberg process is used in Great Britain and the United States. The cooling must be such as not to accentuate the differences resulting from various rates of cooling between the various portions of the section and also between the exterior and interior, the thinner parts of the section and the exterior layers being considerably cooler than the thicker parts and the interior of the head. Accelerated cooling of the rail head is accomplished by the use of atomized water. The best indication of the superiority of these heat treated rails may be judged from the fact that one of the leading railways has already during the last 2 years obtained over 20,000 tons of rails treated by the Sandberg new regulated process for use on their extensive electrified system where there is particular need of a super quality rail, and are now ordering this quality exclusively for their electrified lines. CMS (5b)

Charging and Hardening of Large Quantities of Small Parts (Das Einsetzen und Härten von Massenteilen) C. ALBRECHT. *Feinmechanik & Präzision,* Vol. 44, June 1936, pages 97-99. Furnaces, quenching arrangements, temperature control and layout of installations are discussed. Ha (5b)

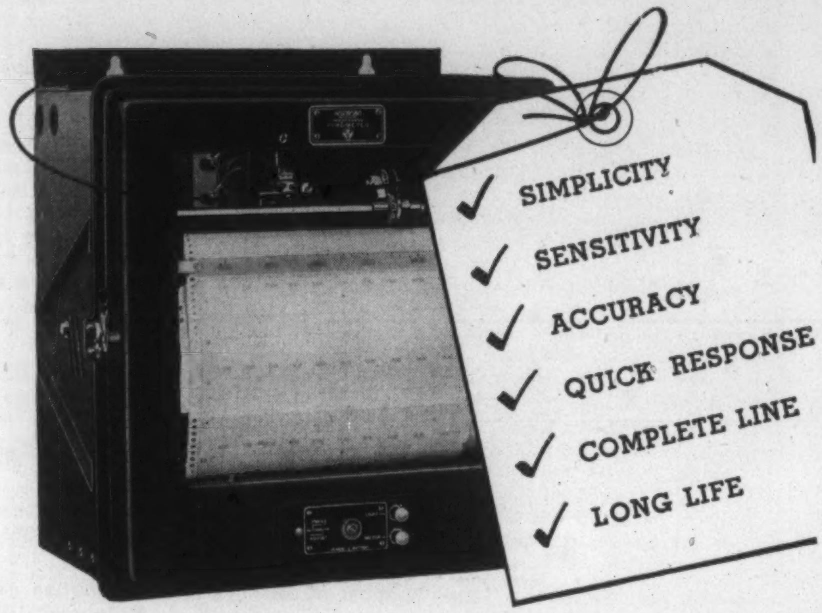
MISCO
Heat and Corrosion Resistant Alloys

Let's check what you need in a PYROMETER!



Let's check what Foxboro gives you. Foxboro gives you a dependable mechanism that is mechanically and electrically simple. You get instant response to thermocouple temperature changes. Every variation in temperature is quickly shown. You get a guaranteed accuracy of ¼ of 1% of scale range and a clear record on a 12-inch wide chart. Available is a comprehensive choice of models and ranges to meet precisely your specific requirements and above all you get all of these qualities year after year. Time does not impair the accuracy and responsiveness of Foxboro Potentiometer Recorders.

Give any Foxboro Pyrometer "the ear test." Listen carefully while it operates. It's almost noiseless. The Foxboro recording system operates at moderate speed and yet gives you speedy recording. Wear is reduced to minimum.

You'll find all the features, including the extra compensating slide-wire, described in detail in Bulletin 190-1. A copy is yours for the asking.

Solve Your Air Supply Problems Like This

The next time you buy heat-treating equipment, ask your manufacturer to mount the Spencer Turbo-Compressor on the unit. The clean-cut and practical installation shown below is a typical example.

Only a Spencer can combine the required qualities of simplicity, small size, freedom from vibration and the reliability necessary for applications like this.

And throughout the years it has been the Spencer with its centrifugal design, light-weight impellers and wide clearances that has won the outstanding recognition of metal men in all branches of the industry.

Such installations not only look neat and businesslike but often enable entire departments to clean up their layouts and reorganize their production methods.

While on this subject, don't forget that Spencer Vacuum Cleaning Systems are being used more and more every year, particularly where dirt or dust are injurious to employees or the finished product.

May we look over your plant and suggest what might be saved by cleaning the Spencer way?

J-M FIRECRETE
for casting shapes yourself
QUICKLY . . . at low cost

● Use this hydraulic-setting J-M Refractory Cement for pouring door linings, flues and pipes; for dampers and special shapes. Handled like ordinary concrete, Firecrete saves time, labor and expense. And it's exceptionally strong, highly spall-resistant, with practically no drying or fire shrinkage. For details on Firecrete and other J-M Refractory Cements, write to Johns-Manville, 22 E. 40th Street, New York City.

6. FURNACES, REFRACTORIES AND FUELS . . .

M. H. MAWHINNEY, SECTION EDITOR

New Blower Reduces Hazard Involved in Cleaning Out Open-Hearth Taphole. *Steel,* Vol. 98, May 25, 1936, page 75. Blower is a conical shaped steel casting weighing 3 lbs. designed to deliver compressed air through nozzle and 8 rear jets simultaneously. With it, hole can be cleaned out clear up to furnace shell just as large as it was when closed up and without fear of a break-out, in about 1/3 time required for usual digging. Results are straighter, cleaner tapholes, 1-rod taps, and good drainage of furnace. MS (6)

New Thermocouples and Protecting Tubes. *Kachestvennaia Stal,* Vol. 4, No. 6, 1936, page 57. In Russian. Pure Ni-28-32% Cr steel thermocouples were used successfully in the plants for temperatures up to 1100°-1250° C. Their e.m.f. at 1200° C. is twice as large as of Pt: Pt-Rh and their life at this temperature is about 2-3 months. Tubes made of 28-32% Cr steel are used as protecting tubes. In usual operating conditions they last almost indefinitely while 2 to 3 months are required to destroy them at 1200°-1300° C. (6)

Boeing Aircraft Company Modernizes Heat Treating Department. *Heat Treating & Forging,* Vol. 22, July 1936, pages 351-352. **Modern Heat Treating Plant for Aircraft Steel is All-Electric.** *Steel,* Vol. 98, June 8, 1936, pages 49-50. Describes equipment installed in plant at Seattle, Wash. Includes 4 hardening and drawing furnaces; gas atmosphere controller; 3 pot furnaces; 2 oil and 1 H_2O quench tanks; and a gas muffle furnace. In addition to heat treating steel parts, equipment is used for annealing 17 and 24 ST Al alloy sheet. MS (6)

Waste-Heat Boilers in Open-Hearth Practice. *Blast Furnace and Steel Plant,* Vol. 23, Oct. 1935, pages 708-710, 719; Nov. 1935, pages 780-782, 800; Dec. 1935, pages 859-860, 862, 876; Vol. 24, Jan. 1936, pages 87-89; Feb. 1936, pages 167-169; Mar. 1936, pages 241, 247, 254; Apr. 1936, pages 344-345; May 1936, pages 424-425. From Second report of the Open-Hearth Committee of the Iron & Steel Industrial Research Council, published as Iron & Steel Institute Special Report No. 10. See *Metals & Alloys,* Vol. 7, Aug. 1936, page MA 406R/3. MS (6)

Large High-frequency Electric Furnaces (Aus der Praxis mit grossen Hochfrequenzöfen) BOER. *Siemens-Zeitschrift,* Vol. 16, July 1936, pages 255-259. Recent experiences with furnaces of 6-8 tons, 500 cycles and 2300 v. are described. Construction details are given. The furnaces are lined with quartzite which is electrically sintered. Consumption for a 6 ton furnace is 1600 kw., energy consumption per ton 500-600 kw.hr., melting time for high-grade steel scrap with under 0.1% C about 2 hrs.

The Application of Fused Silica in Heating Processes. Part I. -Furnaces and Heated Enclosures. W. L. PATRICK & G. N. PEEL. *Industrial Chemist,* Vol. 12, May 1936, pages 221-226. Resumé of physical properties and a detailed discussion of methods of application in tubular, high-frequency induction and vacuum melting furnaces. RAW (6)

Refractories for Basic Open-hearth Furnaces (Refrattari per i forni Siemens-Martin basici) L. POMPEI. *La Metallurgia Italiana,* Vol. 28, Apr. 1936, pages 145-161. Requirements are outlined and the principal refractories reviewed in the light of the above requirements. AWC (6)

Principles of Theory and Design of Coreless Induction Furnaces. V. I. RUDZIK. *Metallurg,* No. 3, 1936, pages 77-89. In Russian. (6)

Electric Annealing Furnaces and their Heating Elements. W. ROHN & JOHN E. W. GINGER. *Metallurgia,* Vol. 14, May 1936, pages 7-9; *Heat Treating & Forging,* Vol. 22, June 1936, pages 299-301, 307. See *Metals & Alloys,* Vol. 7, July 1936, page MA 348R/8. JLG + MS (6)

Heating Furnaces for Hot-pressing of Aluminum Parts (Anwärmeöfen zum Warmpressen von Aluminiumteilen) K. ROBERTZ. *Aluminium,* Vol. 18, July 1936, pages 293-297. The special demands which are made on heating furnaces for Al are discussed and explained by description of installations. For small plants and if there is no particular necessity for uniformity of material simple muffle furnaces can be employed, while for good uniformity and especially for heating of previously pressed material semi-continuous furnaces are preferred in present practice. If operations are continuous, in 3 shifts per day, and particularly if large production is required in small space, continuous furnaces with vertical shafts (paternoster furnaces) are recommended. Ha (6)

Destruction of Melting-furnace Refractories by Softening and Melting (Die Zerstörung feuerfester Schmelzofensteine durch Erweichung und Schmelzen). E. T. RICHARDS. *Feuerungstechnik,* Vol. 24, May 1936, pages 73-77. 7 factors affecting the softening and melting points of furnace refactories are listed and discussed. Chemical, physical and design conditions are shown to be of greatest importance. Destruction can be minimized by (1) protection of the refractory against excessive surface pressure through appropriate arch design, and careful preparation of the refractory surface before insertion and (2) protection against contaminations that lower the melting point through attention to the porosity of the material and treatment with carefully selected pore-closing substances.

A Little Higher in Unit Cost! **Much Lower in Cost Per Heat!**

P. B. SILLIMANITE RAMMING MIX

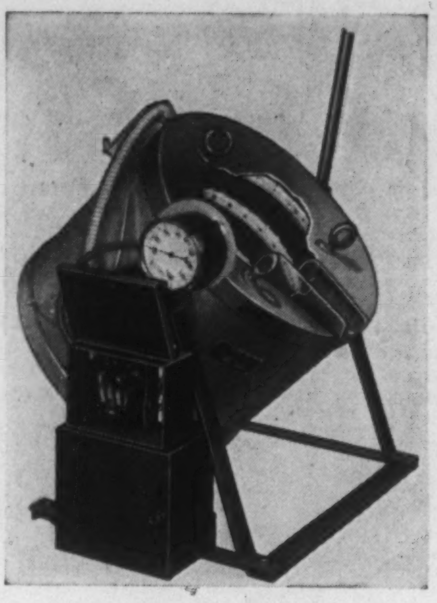
A nationally known manufacturer writes: "We have found the Ramming Mixture very much superior to Silica Brick, and even though the unit cost is higher, the cost per heat is much less."

Also P. B. Sillimanite Ramming Mix and P. B. Sillimanite Patch, used in a Moore 'Lectromelt furnace give excellent results and entire satisfaction. Thus, one of our customers tells the story more effectively than we can. In the last analysis, it is what the customer says that really counts.

If yours seems to be a difficult problem, tell our Engineering Department. We may be able to acquaint you with advantages you have never known before.

All P. B. Sillimanite made by The Chas. Taylor Sons Company bears this trade-mark—your guarantee of satisfaction.

THE CHAS. TAYLOR SONS CO.
CINCINNATI, OHIO



Electrically heated Babbitt Pot manufactured by Harold E. Trent Co., Philadelphia in which Kanthal is employed as the heating element.

Why KANTHAL is Chosen!

Here is an application of Kanthal made by one prominent electric furnace manufacturer. He uses Kanthal because in its several forms, more compact units are possible (greater resistance being obtained with shorter wires); longer life is assured (Kanthal's high resistance rating giving greater operating economy); costs are reduced (Kanthal D, for instance, with 15% lower specific gravity produces more units per lb. of material) and corrosion factor practically eliminated (particularly where sulphurous fumes are present).

Ask us for other demonstrations where Kanthal has opened up new doors of opportunity to manufacturers of electric heating apparatus.

The C. O. Jelliff Mfg., Co.
SOUTHPORT, CONN.

Operation of Large-size Coreless Induction Furnaces. FRIEDRICH BARDENHEUER. *Steel*, Vol. 98, May 11, 1936, pages 46-50. Translated from *Stahl und Eisen*, Vol. 55, pages 821-825. See *Metals & Alloys*, Vol. 6, Dec. 1935, page MA 494L/8. MS (6)

Blast Furnace Design and Dimensions. M. A. PAVLOFF. *Engineering*, Vol. 142, July 24, 1936, pages 105-106. Abridged from a paper read at the International Congress of Mining, Metallurgy, and Applied Geology, Paris, Oct. 1935. See *Metals & Alloys*, Vol. 7, Apr. 1936, page MA 189L/7. VSP (6)

The Properties of Open-hearth Checker Bricks. T. SWINDEN & J. H. CHESTERS. *Iron & Coal Trades Review*, Vol. 133, July 3, 1936, page 13. Investigations of melting point, cold crushing strength, specific heat and thermal conductivity, heat capacity and diffusivity were made to determine the most suitable materials for use in the checkers of open-hearth steel-melting furnaces. It could be concluded that a strong similarity is found in such of the physical properties of fireclay and semi-silica bricks as would affect their use in open-hearth furnace checkers. Used checker bricks, provided they are unglazed and can readily be freed from dust, can be re-used without any loss in efficiency. The principal materials responsible for the corrosion of steel furnace checker bricks are Fe oxide (45%) and lime (10%); although other materials, notably Zn oxides and alkalis may be present in considerable amounts. Ha (6)

Drill Steel Tempering Furnace. W. V. DECAMP. *Engineering & Mining Journal*, Vol. 137, July 1936, page 344. An automatic lead-bath tempering furnace is described and illustrated. Features are simplicity of design and automatic operation. WHB (6)

Electric Furnace in the Gray Iron Industry. A. H. GREISSER. *Electrical West*, Vol. 76, June 1936, pages 151-156. Report of the Utilization Committee, Engineering and Operating Section, Northwest Electric Light and Power Association. Enumerates advantages of the electric furnace over the cupola for production of ordinary gray-Fe; outlines costs of operation with special reference to Pacific Northwest; gives specifications for furnaces of the direct-arc and single-phase, indirect-arc rocking types; tabulates operating results on small gray-Fe and steel furnaces; and discusses voltages and current regulation, electrodes, linings, and absorption of metal by linings. MS (6)

Some Factors Affecting the Durability of Refractories. J. F. HYSLOP. *Metal Treatment*, Vol. 2, Summer 1936, pages 86-88. The service behavior of a refractory depends on its thermal expansion, volume stability, strength under load, and its resistance to thermal shock, corrosion, abrasion, and the action of furnace atmospheres as well as on its refractoriness. JCC (6)

Wire Bakers, Past and Present. K. B. LEWIS. *Wire & Wire Products*, Vol. 11, Sept. 1936, pages 423-425. Development and present methods of indirect-fired convection-baking are discussed. Ha (6)

SAVED TWO LADLES

- Ladles lined the ordinary way, with a two-inch lining of clay and fire sand, hold 15% less metal than those lined the modern LUXIT way. This modern, many-purpose refractory cement gives you a ladle lining only three-quarters of an inch thick, but it holds heat longer than the ordinary lining.

In other words, eleven LUXIT-lined ladles hold more metal than thirteen old-fashioned ladles. You may save two ladles with LUXIT,—and eliminate the man power required to push them. But this saving is only half the story.

Here is the other half. LUXIT linings last from six to ten weeks. Contrast this with the life of ordinary linings. Here are savings in time and material that can be written in good black ink on the right side of the operating statement.

Try lining your ladles with LUXIT, and remember its many advantages when you

- Line or patch cupolas and furnaces,
- Lay brick in cupolas and ladles,
- Want an efficient slurry wash.

Let us give you further details on this modern refractory cement. . . . Write us today.

Open Hearth Furnaces, Factors to be Considered in Insulation. Gilbert Soler. *Iron & Steel Engineer,* Vol. 13, Feb. 1936, pages 11-13. Discussion of the application of insulation to open hearth furnaces. Factors affecting choice of insulation, manner and place of application must be closely studied. Design, type of fuel and introduction of the insulation idea to the operating personnel are important factors in the success of insulation. WLC (6)

Coal and Its Mineral Matter with Reference to Carbonization. A. W. Gauger. *Blast Furnace & Steel Plant,* Vol. 24, Apr. 1936, pages 310-312, 334; May 1936, pages 406-409; June 1936, pages 508-510. Paper presented before the Eastern States Blast Furnace & Coke Oven Association, Feb. 7, 1936. Discusses mineral matter in coal and the physics and chemistry of certain inorganic compounds of importance in both the by-product coke-oven and blast-furnace. MS (6)

Liquefied Petroleum Gases Finding New Uses in Metal Treating Plants. Martin J. Conway. *Steel,* Vol. 98, June 15, 1936, pages 34-36. Paper before National Association of Power Engineers. Discusses distribution, advantages, and uses of liquefied C_3H_8 and C_4H_{10}, gives specifications, and tabulates principal properties and combustion data. Increasing industrial applications include metal cutting, atmospheric control, particularly in bright and clean annealing and in gas carburizing, and firing of practically every general kind of heating and heat treating furnaces. MS (6)

Oven for Drying Hand Ladles. S. I. Chetvertukhin. *Liteinoe Delo,* Vol. 7, No. 6, 1936, pages 36-39. In Russian. Structural features of an efficient dryer for small ladles. Optimum temperature for drying is 280°-300° C. and the ladles should be treated in an upright position. (6)

A New Combination Color Pyrometer with Comparison Lamp (Ein neues kombiniertes Farbpyrometer mit Vergleichslampe) G. Naeser. *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Düsseldorf, Vol. 18, No. 2, 1936, pages 21-25. See *Metals & Alloys,* Vol. 7, Aug. 1936, page MA 406R/8. Ha (6)

Coke Saved, Hazard Reduced by Safety Blowpipe for Blast Furnaces. F. L. Prentiss. *Iron Age,* Vol. 138, Aug. 6, 1936, pages 28-30, 94. Describes the new blowpipe developed by Arthur G. McKee & Co., Cleveland, and the Michigan Steel Casting Co., Detroit. The safety blowpipe is an insulated pipe of 2 tubular members, one within the other. Inner tube is a centrifugally cast heat resisting member. Blowpipe is of simple construction and is quickly interchangeable for old type of cast Fe pipe. It is claimed to eliminate hazard of furnace operation and marked increase in efficiency by saving coke and heat at the tuyere. VSP (6)

Refractories in Metallurgical Industries. John D. Sullivan. *Journal American Ceramic Society,* Vol. 19, Aug. 1936, pages 213-233. General summary of refractory requirements and life in metallurgical industries consuming the greater amounts of refractories is given and effect of refractory developments on performance and life of furnaces is discussed. Basic open-hearth furnace refractory problems as to furnace bottoms, roofs, front and back walls, ports and bulkheads, checker chambers, tap holes, ladle linings and nozzles are detailed. Furnace operators report 10-25% increased roof life after insulation. Acid open-hearth furnace, Bessemer converter, Fe-blast furnace, heating furnaces, Fe cupola, malleable Fe air furnace are detailed as to present practice in refractories. The same is done for by-product coke ovens, Cu blast furnace, reverberatory Cu smelting furnaces, converters, Cu anode refining furnaces, wire bar, Zn distilling, continuous Zn distilling furnaces, Pb smelting, Pb refining, direct-arc furnaces with acid and basic linings, indirect-arc furnaces and induction-electric furnaces. New developments and trends in refractories reviewed. WB (6)

Automatic Control Increases Wire Galvanizing Efficiency. L. E. Smith. *Industrial Gas,* Vol. 15, Sept. 1936, pages 17-19, 23. Improvements made by new arrangement of gas burners and refractory layer at the bottom of the galvanizing kettle are described; they resulted in closer temperature control, decreased dross formation and lower maintenance costs. Ha (6)

Pouring Pit Refractories and Their Effect on Alloy Steel Quality. Edward E. Callinan. *Brick & Clay Record,* Vol. 88, June 1936, pages 229-331; *Iron Age,* Vol. 138, July 16, 1936, pages 46, 48, 114-115. From a paper read before the Ohio Ceramic Industries Association. Ladle brick nozzles, sleeves, hot tops and plugs are discussed with reference to their requirements in the production of quality alloy steel. CBJ + VSP (6)

Heat Transfer in Continuous Re-heating Furnaces. J. E. Eberhardt & H. C. Hottel. *Heat Treating & Forging,* Vol. 22, Mar. 1936, pages 144-149; Apr. 1936, pages 193-198; *Blast Furnace & Steel Plant,* Vol. 24, Apr. 1936, pages 338-343, 361; May 1936, pages 419-421, 431. Joints in Tear Gas Projectiles Are Made by Electric Furnace Brazing. *Steel,* Vol. 98, Apr. 13, 1936, pages 44, 47. See *Metals & Alloys,* Vol. 7, July 1936, page MA 352R/9. MS (7a)

Some Practical Notes on Brazing Metals with Modern Alloys. A. Eyles. *Sheet Metal Industries,* Vol. 10, Apr. 1936, pages 330-332. The author discusses the use of silver solders with particular reference to "Silfos." The need for cleanliness and the regulation of heating are stressed. AWM (7a)

Soldered Joints in Aluminum Cables (Lötverbindungen in Aluminiumkabeln) G. Kramer. *Elektrotechnische Zeitschrift,* Vol. 57, June 1936, pages 675-677; *Aluminium,* Vol. 18, July 1936, pages 299-302. A soft soldering method with a reaction solder and a special flux to remove the oxide layer on the Al surface is described. Ha (7a)

Electric Brazing. A. G. Robiette. *Electrical Review,* Vol. 118, June 5, 1936, pages 816-817. Outlines principles, equipment, applications and advantages of brazing in continuous electric furnaces with controlled atmospheres. Parts to be joined are fitted within 0.001″-0.03″ and Cu or other brazing alloy is placed close to the joint. Assembly is passed into an electric furnace having an atmosphere of partially combusted coal-gas at a temperature slightly above m.p. of brazing alloy. Molten alloy flows into joint by capillarity. Flux is not normally used. Parts are cooled in a cooling chamber having same atmosphere. Several joints can be brazed at one time permitting a complicated article to be built up from a number of components, such as stampings, pressings, and small machined parts. Properly designed brazed assembly of mild steel fractures in tension at a point remote from the joint. As only the minimum of brazing alloy is required, no subsequent cleaning is necessary. Parts can be heat treated after brazing. This process is often cheaper than other joining methods. At present its widest application is to steel parts using brass or Cu as brazing alloy. Recent work indicates it has possibilities for non-ferrous metals such as brass and Ni alloys; Ag solders being used for brazing. MS (7a)

E. V. DAVID, SECTION EDITOR

Design and Construction of Gears and Gear Cases Employing Cast and Rolled Steel Assembled by Welding. Everett Chapman. *Welding Engineer,* Vol. 21, May 1936, pages 32-37. Paper presented at Annual meeting of American Gear Manufacturers Association, Apr. 21, 1936. General discussion of joining of cast and rolled sections by welding, and metallurgical and stressed structures obtained with welds with and without preheat, etc. WB (7b)

Alloy Steels for Welded Power Piping. J. R. Dawson. *Welding Journal,* N. Y., Vol. 15, June 1936, pages 18-23. Better thermal efficiency at higher steam temperature and pressure is pointed out and most important property of steel for this service is considered to be creep strength. Creep resistance of 9% Cr steel and 18-8 is shown to be considerably higher than C steel at 900° F. Internal and external corrosion problems are best met with the alloy steels. Internal corrosion is caused by O_2 from decomposition of steam and dissolved O_2 in water. External corrosion of economizer tubes, etc. comes from S in combustion gases, H_2SO_4 in vapor at dew point, etc. Welding is of advantage in installation of piping due to more effective insulation. There is less danger of leakage than for mechanical joints and piping layout can be more compactly arranged. Properties of the low Cr, 18-8 steels are detailed and use of Cb, N_2 in steels for embrittlement resistance and grain refinement respectively is discussed. WB (7b)

What the Electric Arc Means to People of Foreign Lands. A. F. Davis. *Metal Progress,* Vol. 29, May 1936, pages 59-60. General description. WLC (7b)

The Electronic Tornado. Automatic Arc Welding (El Ciclon electronico. Soldadura al arco automatica) A. F. Davis. *Metalurgia y Construccion Mecanica,* Vol. 2, Apr. 1936, page 7; May 1936, page 5; June 1936, page 7. The development of the "electronic tornado" process, the equipment used, and its applications are discussed. FRM (7b)

Maintenance of Way Welding. C. A. Daley. *Welding Journal,* N. Y., Vol. 15, May 1936, pages 14-18. Sphere of recommended uses for arc and oxy-acetylene welding in building up battered rail ends is discussed. Procedure in reconditioning rails differs from the more economical "reforming" practice where metal is added to bring rail ends to same level and surface fusion method where rail end is preheated quickly on the surface almost to fusion temperature and new metal added. Heat treating by water quench from 1500° F. down to 300° F. and reheat to 650° F. air cool is described as practiced for rail ends built up in field. Drawing temperature is checked by testing rail end with 50-50 solder struck across heated surface. WB (7b)

Welding in Aviation. CARL DE GANAHL. *Sheet Metal Industries,* Vol. 10, May 1936, pages 411-412. From a paper before the New York section of the American Welding Society. Discusses oxy-acetylene welding of Cr-Mo and spot welding of stainless steels. Brings out the action of Ti and Cb in preventing intergranular corrosion. AWM (7b)

The Present Status of Welding of Non-ferrous Metals (Der gegenwärtige Stand des Schweissens von Nichteisenmetallen) C. STIELER. *Zeitschrift Verein deutscher Ingenieure,* Vol. 8, May 23, 1936, pages 657-660. The use of welding of non-ferrous metals has increased lately largely due to development of modern welding processes, as arcatom-welding, and resistance and gas welding. Methods for welding of Cu and Cu alloys, Zn, Pb, Ni and Ni alloys, Al and Al alloys, their peculiarities and handling, are described. Fluxes and means for controlling the welding process automatically by electronic devices are discussed briefly. Ha (7b)

Influence of Electric Arc Characteristics on Nitrogen Absorption by Liquid Steel. A. A. SHATALIN. *Metallurg,* Vol. 11, June 1936, pages 19-34. In Russian. Comprehensive presentation of the theoretical aspects of the subject taken from published literature precedes description of experimental practice. A 2 kg. furnace with spherical working space was used. Temperature measurements could not be made accurately. Analysis showed that electric arc induces N absorption, greatest influence being exerted by the portion of arc close to metal. Lengthening of arc with a constant power increases N absorption up to a certain point after which further lengthening does not have any effect, other factors being constant. In electric welding this point is never reached so that with changing length of arc N absorption capacity of the weld varies. In arc furnaces this point is always passed so that N content of steel does not depend on the length of arc, provided power is constant. (7b)

Radiography of Welds (Technique de la Radiométallographie des Soudures) ROBERT SCHMIDT. *Bulletin de la Société des Ingénieurs-Soudeurs,* Vol. 7, Jan.-Feb. 1936, pages 2069-2082. Lecture before the French Welders' Society. Gives characteristics of X and gamma rays and of radiography apparatus. Radiography has shown what added metals to use in order to reduce porosity in welds and to establish best practice for making sound welding joints. When defects are found it is easy to eliminate them by correct repair work. Radiographs of sound welds show the user of products what he can get with welding process when correctly made and controlled. FR (7b)

Repairs of Fractured Cast Engine Parts and Replacement with Wrought Iron by Acetylene Welding (Instandsetzungsarbeiten an gebrochenen Maschinenteilen sowie Neuanfertigung aus Schmiedeeisen mittels Azetylenschweissung) J. J. THIESSEN. *Autogene Metallbearbeitung,* Vol. 29, June 15, 1936, pages 185-188. To avoid the danger of fractures and cracks in castings at other places when repaired by welding the pieces should be preheated. Examples are described in which new wrought Fe parts were successfully welded to cast Fe pieces where repair was impossible. Ha (7b)

Modern Process in Forging Craft with Particular Consideration of the Acetylene Welding and Cutting Technique (Neuzeitliche Arbeitsverfahren im Schmiedehandwerk unter besonderer Berücksichtigung der Azetylenschweiss- und Schneidtechnik) J. J. THIESSEN. *Autogene Metallbearbeitung,* Vol. 29, July 15, 1936, pages 215-218. A number of examples illustrate procedures for using the welding torch advantageously in the small shop in fabricating forged parts. Ha (7b)

Welded Piping and Pressure Vessels in the Marine Field. JAMES W. WILSON. *Welding Journal,* N. Y., Vol. 15, Mar. 1936, pages 6-7. See *Metals & Alloys,* Vol. 7, July 1936, page MA 355L/2. WB (7b)

Welding Viewed from a Somewhat Different Angle. T. HOLLAND NELSON. *Steel,* Vol. 98, May 11, 1936, pages 79, 81. Abstract of paper before interchapter meeting of American Society for Metals at Pennsylvania State College, May 1-2. Discusses phenomena occurring in parent metal and weld-metal, and condition of the metals after welding and heat treating, with chief attention to alloys. Shows in shot welds of 18-8 Cr-Ni steel, that solidification of molten metal forms rings, number depending upon number of cycles of current used in making weld. Rings are formed because molten metal begins to freeze in extremely brief period between cycles. Each weld has a corona or area of metal affected by heat of weld. Weld can be so controlled that corona does not reach metal surface. Intergranular corrosion will result when corona affects 18-8 surface. In discussion, E. C. Bain contended that piping is likely to occur in welds unless metal is compacted as shown by indentations. Author stated that latter are due to pressure of electrodes and that it is possible to make shot welds without surface indentations and the welds show no piping. MS (7b)

Accurate Time Control for Resistance Welding. R. T. GILLETTE. *Welding Journal,* N. Y., Vol. 15, June 1936, pages 6-8. The necessity for close control of timing in spot welding of high C stainless steels, Al, Ni, etc. is discussed and shown to make the difference between a good weld and a reject. Details are given of seam and intermittent welds on evaporator bodies made from .025" thick 18-8 of .12% C. Rejects are less than 1/10% since application of accurate timing. WB (7b)

Welded Frame in Hydraulic Press. GEORGE M. GILLEN. *Welding Journal,* N. Y., Vol. 15, May 1936, pages 12-13. A 15,400 lb. frame is illustrated and details described briefly, weight saving (over cast design) due to welding for completed press estimated as 12,000 lbs. WB (7b)

Recent Progress in the Welding of Aluminium and Its Alloys. JACQUES DOUCHEMENT. *Aluminium & the Non-ferrous Review,* Vol. 1, May 1936, pages 391-396. See *Metals & Alloys,* Vol. 7, June 1936, page MA 299L/6. JCC (7b)

Autogenous Welding in Pipe Line Construction (Autogenschweissung im Rohrleitungsbau) F. WECKWERTH. *Autogene Metallbearbeitung,* Vol. 29, June 1, 1936, pages 161-166. Methods of joining pipes and sections to long lines by welding, handling and putting in place pipe lines of 200 m. length, and equipment used are described and illustrated. Ha (7b)

Resistance Welding Extensively Employed in Automotive Industry. J. A. WEIGER. *Iron Age,* Vol. 136, Nov. 7, 1935, pages 20-24, 102. Outlines progress made during last few years in electric resistance welding in automobile industry. Trend has been from simple to semi-automatic and fully automatic machines. Covers spot welding flash butt-welding, electrical upsetting, seam welding and projection welding. Water cooling and proper electrode and die material and design are essential. VSP (7b)

8. FINISHING

H. S. RAWDON, SECTION EDITOR

Protective Finishes on Zinc. S. W. K. MORGAN & L. A. J. LODDER. *Aluminium & Non-Ferrous Review,* Vol. 1, Mar. 1936, pages 232-237. Read before the Midland Centre of the Electrodepositors' Technical Society. JCC (8)

8a. Pickling

The Acid Cleaning of Sheet Steels. RICHARD SAXTON. *Sheet Metal Industries,* Vol. 10, Mar. 1936, pages 211-212. H_2SO_4 is recommended over HCl from a cost standpoint. A 6% H_2SO_4 bath at about 90° C. will give an output roughly 4 times that of an equal volume of HCl at atmospheric temperature. Elimination of H by heating to 200° to 250° C. or by immersion in boiling water is suggested. AWM (8a)

Pickling and Plating Brittleness of Steel. H. SUTTON. *Iron & Steel Industry,* Vol. 9, June 1936, pages 394-395. Electrolytic pickling may be effected in acid baths without embrittlement of the steel. Important conditions to be observed are, (a) low or moderate temperature of the bath, and (b) high initial current density, e.g., 100 amps./ft.^{2} the pieces being made the anode. A convenient bath contains about 30% H_2SO_4, by volume, and about 3 oz./gal. of K dichromate. The cleaned pieces are removed quickly from the bath, rinsed and transferred directly to the plating bath, if plating is desired. CEJ (8a)

8b. Cleaning including Sand Blasting

Modern Derusting Processes (Neuzeitliche Entrostungsverfahren) FR. KAPPLER. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, June 20, 1936, pages 781-784. Freeing of metal parts from rust by mechanical means, as by steel brush, tapping, sandblasting, sparking (i.e. by throwing steel grit rapidly onto the surface to be cleaned so that sparks are produced), and by chemical means, as pickling, are reviewed and the respective fields of application discussed. Ha (8b)

8c. Polishing & Grinding

Control of Abrasive Dust. Part I. FRED B. JACOBS. *Mill & Factory,* Vol. 19, July 1936, pages 45-48. Discussion of grinding methods with particular reference to the need for and existence of dust control. In practically all industries where metals are ground and polished, steps have been taken to eliminate silicosis hazards by installing large central dust collecting systems or small portable dust exhausters for non-stationary work. Wet-sand blasting is said to eliminate completely the dust hazard. Although the inhalation of silica dust is definitely dangerous, the inhalation of emery, silicon carbide or alumina does not seem to result in injury. The need for control of dust appears to be greatest in gray Fe, malleable Fe, steel and nonferrous foundries where the castings are ground dry to remove imperfections. Several grinding operations with and without dust removal equipment are illustrated. FPP (8c)

Polishing and Buffing. S. MUSCIO. *Metal Cleaning & Finishing,* Vol. 7, June 1935, pages 303-304. Describes various types of wheels used—canvas, muslin, (sewed or glued) felt, sheepskin, walrus hide, bullneck, leather, leather-covered, laminated wood and cemented paper discs. GBH (8c)

Cooling and Lubricating Liquids for Grinding (Kühl- und Schmierflüssigkeiten beim Schleifen) F. PACHTNER. *Oberflächentechnik,* Vol. 13, July 7, 1936, page 150. Water emulsions of oils are good for this purpose but the oils must not clog up the grinding discs. Emulsifying oils, as shell oil M2, which take up water in fine droplets, are the best; a mixing ratio 1 oil to 60 water is suitable. The water should not be hard (it may be softened by addition of soda) and not hot. The dilution should be 1:50 to 1:70 for grinding of Fe, steel, cast Fe, malleable Fe, brass, bronze, Cu, Ni, Ni Ag, Zn, Sn, Pb; 1:60-1:70 for Al and Al alloys, but for grinding of elektron a 4% NaF solution with oil should be used instead of water. Insulating materials, hard rubber, ebonite, should be ground dry. Ha (8c)

Using Abrasives in the Foundry. B. N. HODGES. *Abrasive Industry,* Vol. 17, May 1936, pages 16-19. General. WB (8c)

Some Notes on Finishes Produced by Mechanical Means. *Synthetic & Applied Finishes,* Vol. 6, Jan. 1936, pages 256-259. Important features of materials, method and technique used in mechanical finishing as contrasted with organic, electrodeposited or chemically applied finishes are discussed. Burnishing by tumbling is too often ignored; types of barrel, speed, inclination angles, etc. are specified. Other barrel processes are scouring or grinding, and polishing. Sand blasting is discussed as a means of scale removal for the improvement of surface finish or as a key for organic finishes. Types and sizes of sand grit are discussed and compared with more expensive steel grits. Steel grit creates less dust, minimizes safety hazard, reduces necessary screening, and cuts down handling costs. Abrasive polishing and mat-finishing are described from every angle. FPP (8c)

8d. Electroplating

Bright Nickel Solutions. PHILIP SIEVERING, JR. *Platers' Guide,* Vol. 32, May 1936, pages 36-38. Bright Ni plating is a money saver but not a cure-all. The solution has good throwing power which is an advantage on articles with deep recesses. Ni buffing is eliminated which is advantageous with articles with sharp corners. The deposit is uniform over the whole article. WHB (8d)

Tests of Insoluble Anodes of Various Compositions for Electrolytic Zinc Deposition by Standard Method. S. A. PLETNEV & A. L. SOBOLEVA. *Tzvetnuie Metallui,* June 1935, pages 48-54. (In Russian). Investigation of 8 types of Pb and Pb-alloy anodes led to the following conclusions: Best materials for insoluble anodes in electrodeposition of Zn were Pb alloyed with 1% Ag, and Pb electrolytically plated with Pb from fluosilicic acid bath. Commercial Pb and also Pb alloyed with Sb were unsuitable as insoluble anodes. Ternary alloys of Pb-Ag-Ca were also unsuitable because of their low stability. Relative potentials in the electrolysis of Zn were studied. Considerable lowering of voltage caused by destruction of anodes under the influence of current was observed when ternary alloys of Pb-Ag-Ca were used, and also slight lowering with binary Pb-Ag alloy. BND (8d)

Mesle's Chord Method for Measuring the Thickness of Metal Coatings. WILLIAM BLUM & ABNER BRENNER. *Bureau of Standards Journal of Research,* Vol. 16, Feb. 1936, pages 171-184. A study was made of methods for measuring the thickness of an electroplated metal coating at any specified part of the surface. The "chord" method depends upon just cutting through the coating on a plane surface, with a grinding wheel of known radius, or, on a curved surface, with a fine file. In either case the thickness T can be computed from C, the width of the cut, that is, the chord, and R, the radius of the wheel or curved surface, by the equation $T = \frac{C^2}{8R}$. Tests on coatings of known thickness showed that the results are accurate within about 10% for coatings at least 0.0002" (0.05 mm) thick. This accuracy compares favorably with the results obtained by measuring metallographic cross sections, a method that is more laborious and time-consuming than the chord method. WAT (8d)

Wear Resistance. Chromium Plating as an Aide to Durability and Reduction of Frictional Losses. *Automobile Engineer,* Vol. 26, Jan. 1936, page 11. The "Fescol" process is described. It consists in employing fine coatings of Cr to resist wear; Cr is electrically deposited by special methods in extremely thin but hard films which form an antifriction surface and a corrosion-resisting surface. The method is employed particularly for broaching tools, crankshafts and shackle pins. Ha (8d)

Electroplating of Metals. E. J. DOBBS. *Times [London] Trade & Engineering,* Vol. 38, Dec. 1935, page XVI. Discusses reasons for and applications of electroplating. MS (8d)

The Effect of Sodium Fluoride on the Bright Plating Range of Chromium in Chromic Acid Plating Baths. E. CURSCHMANN & H. HEINRICH. *Monthly Review American Electroplaters' Society,* Vol. 23, Feb. 1936, pages 52-54. HF, KF and NaF are substitutes for H_2SO_4 in a chromium solution. A wider plating range is claimed for them. Experiments were conducted in a glass jar 4" x 4" x 8" to determine bright plating range. Temperature 45° C., time of plating 5 min., antimonial Pb anode, polished Cu cathode 1" x 2", electrolyte 250 g./l. CrO_3, recommended concentration of NaF 8 g./l.

Table showing Bright Plating Range

NaF g./l.	Lowest c. d. at which a bright plate was obtained amps./in.^{2}	Highest c. d. at which a bright plate was obtained amps./in.^{2}
6	1.00	2.25
8	1.00	3.75
10	1.00	2.25
12	1.00	1.75

Data for Sulphate Bath

H_2SO_4 g./l.		
1.5	.50 amps./in.^{2}	1.50 amps./in.^{2}
2.7	.75 amps./in.^{2}	1.50 amps./in.^{2}

Electro-plated Gold for Special Purposes. *Synthetic & Applied Finishes,* Vol. 6, Jan. 1936, pages 249-255. Au plating is generally applied as decorative finish or for the protection of metals (Ni-silver, Ag, Ag alloys) that require only thin films for this purpose. In electrical engineering, Au plated contacts are useful because of their resistance to tarnish, good electrical conductivity, high density, by virtue of the good throwing power and high electrochemical equivalent of Au. The production of satisfactory thin deposits from a cyanide electrolyte at 50°-60° C. is described. Surface preparation of metal to be plated consists in degreasing in trichlorethylene or alkali solution followed by a sharp acid dip. A NaCN rinse prior to plating is advocated. Anodes are 24 ct. Au strip. Ni underlay is used for Au plating Fe or steel. Al alloys may be Au plated directly with a low cyanide electrolyte, or, more rapidly, with a Ni underlay and high cyanide electrolyte. For electrical purposes the use of the Ni underlay is far superior to direct Au plating. Plate is tested for weight and porosity in any case. Advantages of aurous cyanide as the electrolyte solute are discussed, and the analysis and maintenance of Au plating solutions described in detail. Au may be recovered from discarded solutions by reducing with Zn in the presence of $CuSO_4$ and dissolving the Zn in the precipitated Au sludge with HNO_3. FPP (8d)

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., REQUIRED BY THE ACTS OF CONGRESS OF AUGUST 24, 1912, AND MARCH 3, 1933

of METALS & ALLOYS, published monthly at East Stroudsburg, Pa., for October 1, 1936.

State of New York
County of New York } ss.

Before me, a Notary Public in and for the State and county aforesaid, personally appeared Philip H. Hubbard, who, having been duly sworn according to law, deposes and says that he is the Business Manager of METALS & ALLOYS and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management, etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, as amended by the Act of March 3, 1933, embodied in section 537, Postal Laws and Regulations, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are: Publisher, Reinhold Publishing Corporation, 330 West 42nd St., New York, N. Y.; Editor, Edwin F. Cone, 330 West 42nd St., New York, N. Y.; Managing Editor, Edwin F. Cone, 330 West 42nd St., New York, N. Y.; Business Manager, Philip H. Hubbard, 330 West 42nd St., New York, N. Y.

2. That the owner is: The Reinhold Publishing Corporation, New York, N. Y.; Ralph W. Reinhold, New York, N. Y., and L. N. Thompson, New York, N. Y., stockholders.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of total amount of bonds, mortgages, or other securities are: None.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear upon the books of the company but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association, or corporation has any interest direct or indirect in the said stock, bonds, or other securities than as so stated by him.

(signed) PHILIP H. HUBBARD.
Business Manager.

Sworn to and subscribed before me this 9th day of October, 1936,
CURVILLE C. ROBINSON.
Notary Public.

[SEAL] (My commission expires March 30, 1938.)

Certificate filed in Bronx Co., Bronx Co. Clk's No. 52, Reg. No. 37R36; N. Y. Co. Clk's No. 284, Reg. No. 6R154.

The Effect of Oxidizing Agents on Nickel Deposition. II. Chromic Acid. A. W. HOTHERSALL & R. A. F. HAMMOND. *Transactions Faraday Society,* Vol. 31, Nov. 1935, pages 1574-1582. Increasing concentrations of CrO_3 were found to cause a marked decrease in cathode efficiency and to render the deposits first, bright, then exfoliated, then burnt, and finally to result in the complete inhibition of Ni deposition. Greater effects were produced at higher than at lower pH values. Low concentrations of CrO_3 produced little, if any, diminution in gas discharge at the cathode whilst amounts in excess of .03 g./l caused a rapid increase in the rate of gas evolution. Pitting was not diminished. The effects produced can be connected indirectly, to a small degree, with depolarization of H_2. The CrO_3 acid functions in 2 ways: (1) with low concentrations, initial depolarization results in precipitation of basic Ni compounds containing Cr at the cathode and depleting Ni ion concentration and favoring H ion discharge; (2) with higher concentrations, Cr acid reacts chemically with the cathode metal to form a film; Ni deposition is completely inhibited. Different cathodic metals form different types of surface films by interaction with CrO_3. PRK (8d)

The Trend of Recent Developments in Electrodeposited Coatings. A. W. HOTHERSALL. *Metal Industry,* London, Vol. 48, Jan. 17, 1936, pages 115-120. In a survey of progress made in 1935 the author states that progress has been made (a) in improving adhesion, (b) in studying the mechanism of electrodeposition and the properties of deposits, (c) in the reduction of costs and (d) in control of quality by specification. Recent applications of electrodeposition are (1) resistance to wear, (2) improvement in the quality of tinplate and (3) the electrodeposition of bronze. 29 references. HBG (8d)

Electroplating of Aluminum and its Alloys with Zinc, Cadmium, Copper, Nickel, and Chromium. V. I. LAINER & S. I. ORLOVA. *Legkie Metallui,* Vol. 5, Feb. 1936, pages 22-33. In Russian. Specimens were electrolytically degreased, immersed in a basic Na_2ZnO_2 solution, and plated in the usual manner. The coatings were bright, uniform, and adhered well. HWR (8d)

A Unique Tin Plate. T. W. LIPPERT. *Iron Age,* Vol. 138, July 2, 1936, pages 20-23, 84. A new continuous electro-tinning process developed by the Pittsburgh Crucible Steel Co. is described. 5000-lb. coils are continuously and uniformly coated, porosity and other defects being avoided. Claims made for the process are: (1) continuous and uniform coating; (2) dense and lustrous Sn coating with almost complete freedom from pores; (3) elimination of pickling embrittlement and concomitant improvement in deep drawing qualities; (4) surface layer of pure Sn and therefore improved corrosion resistance; and (5) avoidance of grease lines, mottle and isolated $FeSn_2$ crystallites. VSP (8d)

Lead Plated Aluminum (La piombatura dell'alluminio) O. SCARPA. *Alluminio,* Vol. 5, Jan.-Feb. 1936, pages 1-5. Al has been adapted as a substitute for Cu in connecting storage battery terminals. The Al is first coated with Ni and then plated with Pb, the Ni serving as a bond between Al and Pb. A lead fluoborate bath was found suitable for the lead plating. AWC (8d)

The First Installation for Lead-Plating Aluminum Electrolytically (Il primo impianto di piombatura elettrolitica dell'alluminio) O. SCARPA. *Alluminio,* Vol. 5, May-June 1936, page 85. Pictures of the plant at Melzi are shown. AWC (8d)

8e. Metallic Coatings other than Electroplating

Influence of Surface Cuprous Oxide Inclusions on the Porosity of Hot-tinned Coatings on Copper. W. D. JONES. *Technical Publications, International Tin Research & Development Council,* Series A, No. 32, 8 pages. Reprinted from *Journal of the Institute of Metals,* Vol. 58, 1936. See *Metals & Alloys,* Vol. 7, July 1936, page MA 357R/9. (8e)

The Development & Control of Spangles on Galvanized Iron. Part 5. W. G. IMHOFF. *Metal Cleaning & Finishing,* Vol. 7, June 1935, pages 281-284. General discussion of the effect of pickling on hot galvanizing of sheet steel. Overpickling cuts into surface skin and produces poor spangles. Pickling may show up defects in the steel such as slag or oxide inclusions. Blisters in Zn coating are attributed to too high speed through molten Zn and insufficient time for occluded gases or for traces of acid resulting from pickling to be driven off. Opinion is given that "skinned" sheets (having a skin that can be pulled off after pickling) occur with steel having over .6 to .8% Si. GBH (8e)

The Spraying of Molten Metal. L. E. KUNKLER.* *Metallizer,* Vol. 5, Apr.-May 1936, pages 2-5. Relatively fool-proof equipment, the training of operators, and more care in the proper preparation of the surface to be coated have resulted in great improvements in metal spraying. The tensile strength of sprayed metal is low, its compressive strength high. Coatings should never be applied if there will be further fabrication such as bending, rolling, etc. Sand blasting and rough threading are the best means of surface preparation for metallizing. Wet grinding is the best way to finish metal sprayed coatings on shafts and the like. Many applications are cited. BWG (8e)

Action of Molten Zinc on Iron and on Common and Alloy Steels (Action du zinc fondu sur le fer et les aciers ordinaires et spéciaux) I. MUSATTI & A. LA FALCE. *Revue de Métallurgie,* Vol. 33, June 1936, pages 362-370. Round bars 20 mm. in diameter were selected from steels having composition suitable for determining the influence of C, Si, S, P, Cr and Ni on their resistance to attack by molten Zn. Specimens were immersed in a special apparatus (described) in a bath of Zn kept within 1.5° C. at 460°, 480°, 500° and 520° C., for 8 hours. Zn coating was removed with a 5% H_2SO_4 solution to which 2 g./l. of arsenious acid was added, after being studied under a microscope. The loss of weight was the criterion of corrodibility. C increases Zn attack but less than Si which acts quite pronouncedly. S and P have practically no influence. An 18% Cr — 8% Ni and a 12% Cr steel were corroded the same as low C steels. Corrosion ratio is controlled by the layer of Fe-Zn alloy on the surface of steel. When it contains more Fe, its melting temperature rises and diffusing attack is reduced. JDG (8e)

Caesium-oxygen Films on Tungsten. J. H. Lees. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Vol. 21, June 1936, pages 1131-1139. The adhesion of a film of Cs on W is considerably strengthened if the W is first coated with "activated" oxygen which can be obtained by a definite (described) heat treatment, whereby the electron emission is greatly increased. Apparatus and procedure are described in detail, results shown in curves. Ha (8e)

Metallizing in Europe. *Metallizer,* Feb.-Mar. 1936, page 11. Illustrations are given to show the spraying of statues with Zn, window sash with Zn (or Cu, bronze or Pb), and shaft couplings from large trucks on which the bearing surfaces were built up with high C steel. BWG (8e)

Spraying of Babbitt Metal. *Metallizer,* Vol. 5, Apr.-May, 1936, page 6. In lining bearings by spraying, the backing is grit-blasted before spraying, or if tinned in the usual manner, the Sn is heated with a torch to render it soft just before spraying in order to secure a fused bond. Oil must be thoroughly removed before spraying and preferably only a thin lining applied with but a slight excess to be removed by machining or scraping. Sometimes babbitt is sprayed directly on the backing with no tinning. This is followed by the usual bearing casting operation. BWG (8e)

Alloys in the Zinc Bath. G. A. Brayton. *Journal American Zinc Institute,* Vol. 17, 1936, pages 87-93. Pb and Fe alloys of Zn are always present. Although both are detrimental, the latter is very expensive to the galvanizing process, with no known method of eliminating it. No other metal or alloy has been found which materially reduces the dross production. Addition of Sn alone works best in the Zn bath and produces the best results in adherence, uniformity, and appearance of the coating. It has the added advantage of being easily controlled. Al is beneficial in hand-dip pots only. Very little is known about the action of other metals; some experiments with additions have had disastrous results. Cd, perhaps, may deserve a place in the Zn bath, especially when obtainable as byproduct in Zn at a price comparable to the process. Experiments are underway along this line with amounts from less than 0.5% to 83% Cd. BHS (8e)

Applications of Electric Heating in Galvanizing (Les Applications du Chauffage Electrique en Galvanisation). P. Etienne. *Science et Industrie (Electricité),* Vol. 20, Mar. 1936, pages 122-125. Zn coating is obtained electrolytically or by the hot dipping process. The latter is dealt with in the article. Author discusses use of fuel furnaces and electric heating, and describes types of furnaces available. Advantages of electric heating are: accurate control of temperature, savings by reducing dross formation, long life of pots, suppression of pickling after heat treatment and improvement of quality of product. FR (8e)

■ 8f. Non-Metallic Coatings ■

Surface Preparation, Thickness Control Are Factors in Good Enameling Practice. *Steel,* Vol. 98, May 4, 1936, pages 54, 56, 59. Thorough cleaning of metal surface just prior to application of enamel is necessary to eliminate fish-scaling, copperheading, and blistering. Fe salts on the pickled surface not removed by H_2O rinse may be dissolved by dipping in a solution containing 2 oz. Na_2CO_3 and 2 oz. NaCN per gal. H_2O. By giving metal Ni-dip after pickling, adherence of enamel is improved and copperheading and fish-scaling are decreased markedly. For white ground coats, a solution of 8 oz. $NiSO_4$-$7H_2O$/gal. is used; for Co ground coats, 4-5 oz./gal. Best deposit is obtained when pH is 5.6-6.2. About ¼ oz./gal. H_3BO_3, with or without $(NH_4)_2CO_3$ or NH_4OH, is usual buffer compound used as stabilizer. Temperatures used vary from 110° to 190° F. If film of $Fe(OH)_3$ forms on steel during Ni deposition, it can be removed by rinsing in a 0.1% solution of H_2SO_4. This removes film but not the Ni. Loss by chipping can be reduced by use of relatively thin enamel coatings. In one plant it was found that with thicknesses above 0.021″ losses were nearly 7 times greater than those with thicknesses below 0.018″. MS (8f)

Automatic Lacquering, Enameling and Japanning. Charles W. Hardy. *Metal Industry,* New York, Vol. 34, July 1936, pages 247-249. Automatic dipping units give a better finish at lower cost. CBJ (8f)

Surface Coloring of Metals Extended to Stainless Steel. *Steel,* Vol. 98, May 4, 1936, page 59. Describes process developed by Oscar B. Bach consisting essentially of treatment of the oxide film on stainless steel so that it will reflect the desired color. Steel surface is covered with a compound and heated to 350°-400° F. Chief factors are proper composition of compound [not stated] and length of time it is permitted to react with oxide film. It is claimed that by accurate control of process any desired color can be produced. Process may be used only with stainless steel, as it is based on reactions obtained only with steel containing Cr and Ni. Resulting surface is said to be resistant to abrasion. Where unusual fabricating operations are required, or where heat is applied, desired color may be developed after fabrication has been completed. It is claimed also that the treatment increases resistance of stainless steel to corrosion by HF, HNO_3, and other acids. There is a possibility that similar color finishes may be developed on mild steel by addition of small amounts of alloying elements and modification of the process. Definite information on the real merits of the process is lacking. MS (8f)

Paint and Lacquer Problems with Aircraft Materials (Lack-und Firnisprobleme bei Luftfahrzeugen) E. W. J. Mardles. *Farbe und Lack,* Issue 26, June 26, 1935, page 305. The rigorous conditions to which aircraft member surfaces are exposed and the requirements that protective finishes must meet are discussed. FPP (8f)

Anodic Oxidation of Aluminum and Its Industrial Application. The Development of the Aluminum Industry in Japan (Die anodische Oxydation von Aluminium und ihre industrielle Anwendung. Die Entwicklung der Aluminium-Industrie in Japan) *Aluminium,* Vol. 18, July 1936, pages 313-314. Statistics on consumption and production, present status of industry in Japan. Ha (8f)

YOU CAN REPEAT ALMOST EVERY EXPERIENCE IN LIFE —EXCEPT

life-itself

Today is life. Tomorrow is a hope. Yesterday is a dream. Nothing is so dead as a day that has passed. Only the trailing clouds of memory remain.

One *today* upon another *today* — how quickly a decade is built! Youth approaches manhood in high heart, embraces maturity as the period of his conquest, then "remembers with a sigh the days that are no more."

So life goes — like that. NOW is the only opportunity. NOW is the moment of success. NOW men decide — NOW men win or fail.

Are you one of the men who are wondering today what will happen to them tomorrow? Then remember this: *If you take care of today, tomorrow will take care of itself.* And one of the most important safeguards you can take is to be certain your *training* is modern . . . that you are adequately equipped to master the problems of 1937. Today, in almost every line of human endeavor, ambitious men are modernizing their training by spare-time study of International Correspondence Schools Courses. Their action is a guide to you — and NOW is the time to act! Complete information on any subject in which you are interested will be sent without cost or obligation. The coupon is for your convenience. Return it today.

9. TESTING

Design, Construction and Test of a Pair of Built Up Plate Girders Fabricated by Means of Fusion Welding. SAMUEL COUSIN. *Journal South African Institution of Engineers,* Vol. 34, July 1936, pages 317-324. An outline with special attention given to an overload test of the built up plate girders. WHB (9)

■ 9a. Inspection & Defects, including X-Ray Inspection ■

C. S. BARRETT, SECTION EDITOR

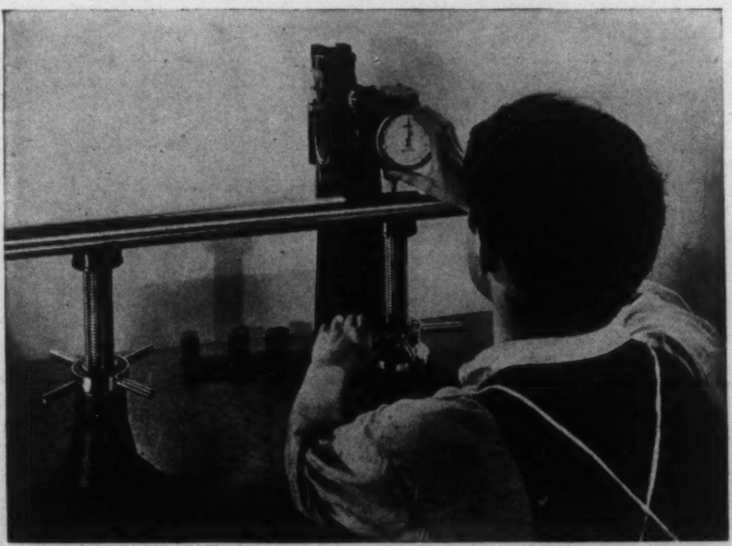
Defects in Forgings and Castings. *Journal of Commerce, Shipbuilding & Engineering Edition,* July 2, 1936, page 7. Description of a magnetic detector for revealing flaws, which consists of a shallow circular brass dish with a thin flat back and a transparent cover. The dish is rendered oil tight and filled with a mixture of magnetic dust and oil, after which it is laid horizontally on the magnetized article; when settling to the bottom the magnetic particles migrate towards the defects if any. JWD (9a)

Non-destructive Testing of Ingot Iron Welds by Means of Gamma Rays (Zerströrmungsfreie Prüfung von Flusseisen-Schweissnähten mittels Gammastrahlung) M. WIDEMANN. *Autogene Metallbearbeitung,* Vol. 29, July 1, 1936, pages 196-199. Experiments are described which prove that welded seams of ingot Fe up to 40 mm. thickness can be reliably tested with γ-rays for defects in binding, fine cracks, blisters. The width of cracks must be at least 0.2 mm. Blisters must have a diam. of at least 2 mm. Ha (9a)

Non-destructive Testing of Heavy-metal Pieces with Ultra-short Wave X-rays (Zerstörungsfreie Prüfung schwermetallischer Werkstücke mit ultrakurzwelliger Röntgenstrahlung) M. WIDEMANN. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, June 13, 1936, pages 741-745. The advantages of X-ray testing with apparatus up to 400,000 v. are explained. Welds, thick and large pieces can be radiographed and defects recorded in short time. Examples are shown. Ha (9a)

Invisible Rays in Modern Engineering. GILBERT E. DOAN. *Steel,* Vol. 98, May 11, 1936, page 68. Paper before interchapter meeting of American Society for Metals at Pennsylvania State College, May 1936. Deals with known electromagnetic rays and their use, especially gamma rays and X-rays in inspection and study of metals. MS (9a)

"ROCKWELL" Testing
for Specification



When moderate sized bars are tested on the "ROCKWELL" the test is not made only on a sample, cut from one end.

Without destroying the bar the test may be made at several points or wherever desired.

The tonnage of high grade steels and nonferrous metals purchased on "ROCKWELL" specifications is enormous, yet done with both confidence and success.

W. A. TUCKER, SECTION EDITOR

The Variations of Young's Modulus with Magnetization and Temperature in Nickel. SIDNEY SIEGEL & S. L. QUIMBY. *Physical Review,* Vol. 49, May 1936, pages 663-670. The relation between Young's modulus, magnetization, and temperature in annealed polycrystalline Ni, 99.7% pure, is determined for values of J, intensity of magnetization, between zero and saturation, and for values of temperature between 23.5° C. and 400° C. The per cent increase in Young's modulus is proportional to J^2 between zero and about 0.4 saturation, at all temperatures below 311° C. The total increase in the modulus from the demagnetized to the saturated state is 6.7% at 23°, reaches a maximum of 18.7% at 185°, and decreases to zero at the Curie point. The method employed for the measurement of Young's modulus yields at the same time a measure of the coefficient of internal friction of the material. The internal friction decreases with increasing magnetization at all temperatures below the Curie point. In the demagnetized material it reaches a maximum value at the same temperature as does the change in elastic modulus. Its value at magnetic saturation is the same order of magnitude as that of a nonferromagnetic substance. WAT (9b)

Determination of Bearing Properties of Metals. N. N. SERAFIMOV. *Metallurg,* Vol. 11, June 1936, pages 102-108. In Russian. Instructions for use, preparation of samples and interpretation of results obtained with Mohr & Federhoff friction testing machine. (9b)

Some Special Test-pieces for the Iron Foundry (De quelques Eprouvettes speciales en Fonderie de Fer.) L. J. GOUTTIER. *Revue de Fonderie Moderne,* Vol. 30, Mar. 10, 1936, pages 75-79; *Foundry Trade Journal,* Vol. 54, Apr. 16, 1936, pages 299-300. By special test-pieces it is intended to signify not those which are generally included in specifications, such as tensile, transverse, hardness, and the like, but those which are helpful in the conduct of one's foundry. A "touch" test piece, porosity test-piece, test piece for internal stresses and test pieces for molding materials are described. The "Touch" and porosity test pieces are of a particular interest. The "touch" method devised by J. Sonnenfeld consists of casting a truncated test-piece in a metallic mold. This method allows an approximate estimate of the sulphur content. The internal wall of this test-piece is carefully polished. Up to 0.07 per cent of sulphur, the surface of the test-piece is quite smooth; when the percentage increases, it becomes rougher and forms thousands of needle points; at 0.13 per cent it is practically impossible to allow the finger tip to touch it; moreover, a careful examination discloses that there are very minute cracks. The porosity test-piece consists of two thin hollow cylinders, arranged in parallel and joined at their centre by a large mass of metal, situated directly under the runner. After cooling, the runner is broken and the test-piece is fractured along the parting line between the two cylinders. A sound fracture, at this place, where the most favorable conditions exist for drawing, indicates that a non-oxidized iron, liable to give sound castings, has been used. The paper is well illustrated. AIK + Ha (9b)

A Deep-drawing Test for Aluminum. A. G. C. GWYER & P. C. VARLEY. *Sheet Metal Industries,* Vol. 10, Apr. 1936, pages 309-311, 324. Paper before the Institute of Metals. See *Metals & Alloys,* Vol. 7, June 1936, page MA 308L/7. AWM (9b)

■ 9c. Fatigue Testing ■

H. F. MOORE, SECTION EDITOR

The abstracts appearing under this heading are prepared in cooperation with the A.S.T.M. Research Committee on Fatigue of Metals. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

Endurance of Case Hardened Gears. O. W. McMULLAN. *Transactions American Society for Metals,* Vol. 24, June 1936, pages 262-280. Paper presented and discussed at Chicago Convention, 1935. See *Metals & Alloys,* Vol. 6, Dec. 1935, page MA 502L/7. WLC (9c)

Endurance Strength Diagrams of Steels at Different Average Tensile Stresses with Consideration of the Shape of the Test Specimen (Dauerfestigkeitsschaubilder von Stählen bei verschiedenen Zugmittelspannungen unter Berücksichtigung der Prüfstabform) A. POMP & M. HEMPEL. *Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Düsseldorf, Vol. 18, No. 1, 1936, pages 1-14. Tests are described which were made for the purpose of determining the influence of a static tension on which is superimposed an oscillating stress; the diagrams were taken on specimens of ground and polished round bars of Cr-Ni and C steels and of these steels as rolled. The tests are described in detail and were made on a Schenck testing machine. The increase of the limiting stress is closely connected with the elastic limit of the material and clearly shown in the curves. A bar machined on all sides causes an increase (7%) of the alternating strength of 1 to 3 kg./mm.^{2} over the bars as rolled. The ratio, alternating endurance strength to tensile strength, showed for both flat and round bars a decrease with increasing tensile strength. 15 references. Ha (9c)

The Influence of Temperature on the Severity of Corrosion Fatigue. A. J. Gould. *Engineering,* Vol. 14, May 8, 1936, pages 495-496. Describes a constant-temperature room and a Haigh-Robertson fatigue testing machine for measuring corrosion fatigue. Tests were conducted on mild steel wire. Composition of steel was: C 0.17%; Si 0.02%; Mn 0.55%; S 0.035%; and P 0.038%. Test pieces were of 150 diam. length. Artificial sea water was used as corrosive medium. Tests were carried out at temperatures from 15° to 45° C. Endurance of the order of 10 million reversals is approximately halved. Includes graphs showing influence of temperature. VSP (9c)

Fractures without Deformation in Boiler Parts (Verformungslose Brüche an Kesselteilen) W. Ruttmann. *Technische Mitteilungen Krupp,* Vol. 4, Mar. 1936, pages 23-29. See *Metals & Alloys,* Vol. 7, July 1936, page MA 361L/4. Ha (9c)

9d. Magnetic Testing

L. REID, SECTION EDITOR

The Deflection of Cosmic-Ray Charged Particles in Passing through Magnetized Iron. W. E. Danforth & W. F. G. Swann. *Physical Review,* Vol. 49, Apr. 1936, pages 582-591. Experiments are described in which the deflections suffered by cosmic-ray electrons in passing through the saturated Fe core of an electromagnet are detected by means of Geiger counters. The observed effects are compared with the results of calculations in which the energy distribution is used as found by Anderson and Neddermeyer with the cloud chamber. In this way it was possible to set limits to the effective magnetic vector within the Fe. Experiments indicate a value lying between the induction B and B/2. Calculation points to the limits 3B/4 and B/4. A theoretical discussion is included in which it is pointed out that all electrons of the same energy will not necessarily experience the same deflection but will show a statistical distribution of deflections with an arithmetic average corresponding to the induction B. The present type of experiment, however, does not give a true arithmetic average and would be expected to indicate, for the effective deflecting vector, a quantity less than B to an extent dependent upon the particular arrangement. WAT (9d)

Variation in the Magnetization of Ni, Permalloy and Ni Single Crystals at High Field Strengths (Über die Änderung der Magnetisierung von Nickel und Permalloy sowie von Nickel—Einkristallen bei Hohen Feldern) Gerd Gerloff. *Zeitschrift für Physik,* Vol. 99, Apr. 2, 1936, pages 585-594. At room temperature in a field of 4000 gausses, the susceptibility of Ni and permalloy reach a limiting value which only varies about 6% when the field is increased to 5500 gausses. This limiting value for Ni is 1.5×10^{-4} (±4%) and for permalloy it is 2.2×10^{-4} (±4%). FHC (9d)

Electromagnetic Testing of Steel Ropes (Elektromagnetische Prüfung von Stahldrahtseilen) H. Mackh. *Archiv für Technisches Messen,* Vol. 5, May 1936, pages T64-65. Measuring methods with a.c. for the inspection of steel ropes in service are described and instruments explained. Ha (9d)

A Theoretical Discussion of the Deviation of High Energy Charged Particles in Passing through Magnetized Iron. W. F. G. Swann. *Physical Review,* Vol. 49, Apr. 1936, pages 574-582. A critical discussion of the situation pertaining to the magnetic field in a piece of magnetized Fe, particularly in relation to the deflecting force which it produces on high speed charged particles passing through it, is made. On the Lorentzian theory the magnetic induction, B, is the average value of the true magnetic field H, averaged throughout the magnetic material. In this average, regions inside the magnetic entities responsible for the polarization make contributions which determine the whole difference between B and the ordinary macroscopically defined field, h, equal to $B - 4\pi I$. A study is made of the special case where the entities are rotating electrically charged spheres. If the entities are very small in volume the chance of a point electron missing all of them in its passage through a reasonably small length of the magnetized material is considerable. It appears that for such electrons as miss the entities the effective deflecting force is determined on the average by $h + 2\pi I$. The true average for all electrons passing through the material is determined by $B = h + 4\pi I$; but, that average is contributed to in appreciable amount by very few electrons which experience deflections much in excess of those determined by B. WAT (9d)

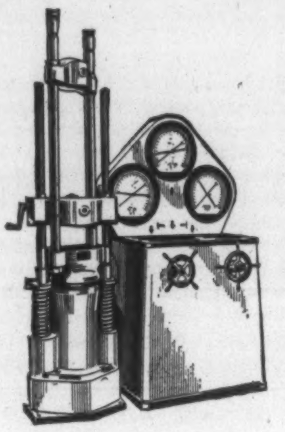
9e. Spectrography

L. W. STROCK, SECTION EDITOR

A Photometric Method Suitable for Spectrum Analysis. D. H. Follett. *Journal of Scientific Instruments,* Vol. 13, July 1936, pages 221-228. A method of determining the relative intensities of two spectral lines of nearly the same wave-length is described. It is based on the use of the "stepped wedge" made by depositing Pt on fused silica. Microphotometric readings are taken on the density of 2 consecutive steps on one line of a pair, and a similar reading on a step of intermediate density on the other. An expression is derived from which the relative intensities of the lines can then be calculated. Tests show that the accuracy of the method is such that the probable error of a single determination is about 1½%. Preliminary results of an application of the method to the quantitative analysis of Pb and Sn are given. RAW (9e)

The Use of the Spectrograph in Industry. H. W. Lohse. *Sands, Clays & Minerals,* Vol. 2, Apr. 1936, pages 133-141. Principles of spectrometry, methods of application for industrial routine purposes, and apparatus are described. Tables of flame spectra and analyses of minerals and solutions are added. 15 references. Ha (9e)

Leadership in TESTING methods and equipment



The Hydraulic Testing Machine is rapidly, replacing the old mechanical machine because of its inertialess action, its self-indicating function, its flexibility and ease of operation.

It is the modern method of handling all physical testing problems—representing so great an improvement over previous means that it is not only replacing large numbers of old mechanical machines in the leading testing laboratories, but it is extending the use of testing machines among a great many people who never before have used them.

For instance—recent designs of self-contained, lightweight, rapidly operating testing machines which are fully protected by all forms of safety devices—which require no foundations—which can be moved about and plugged into any convenient electric socket—have created an entirely new conception of the testing machine's versatility, not only in research but in the control of routine mill operations.

Also, as the functions of testing machines are increased and further refinements are added, prices do not increase. In fact, in many cases they have shown a downward trend, due to the increased number sold.

Southwark has achieved and maintains a position of unquestionable leadership in the hydraulic testing machine field, because it was largely due to Southwark pioneering of the modern hydraulic testing machine that it has reached its wide use in almost every kind of industry and in the most renowned of the engineering school laboratories. It is due to Southwark's sound engineering and careful workmanship that these testing machines have so far exceeded expectations of reliability and accuracy that their merit is universally recognized.

10. METALLOGRAPHY

J. S. MARSH, SECTION EDITOR

Mechanism of the Decomposition of Al-Mg Solid Solutions (Mécanisme de la Décomposition des Solutions Solides Aluminium—Magnésium) PAUL LACOMBE & GEORGES CHAUDRON. *Comptes Rendus,* Vol. 202, May 25, 1936, pages 1790-1792. To show the change in solution potential of an Al alloy containing 9% Mg when annealed at different temperatures, a comparison was made of an electrode of the alloy against the standard calomel electrode in an aerated solution of 3% NaCl.

Heat Treatment	Quenched	Reheated 300° C.	Reheated 200° C.
Potential in Volts	— 0.800	— 0.820	— 1.07

The constituent precipitated at a lower temperature is unstable and richer in Mg than the intermetallic compound Al_3Mg_2 which is the β phase. This is analogous to the beginning of precipitation of Cr carbide in Fe-Ni-Cr alloys which leaves the surrounding areas Cr poor. FHC (10)

Orientation of Oxide Films on Iron. R. F. MEHL & E. L. MCCANDLESS. *Nature,* Vol. 137, Apr. 25, 1936, page 702. Fe_3O_4 formed by decomposing films of FeO on single crystals of Fe was found to be identical in orientation with the parent FeO phase. Parallel orientations were likewise found between a natural crystal of Fe_3O_4 and the FeO phase grown on it by reduction. The reason for different rates of oxidation of different grains (even when only cubic oxide is formed) must be sought in this relationship, and in the lattice conditions it produces at the interface, since diffusion in cubic materials is probably isotropic. The discontinuity in rate of oxidation at the A_3 point is considered to be a result of different orientation relationships of oxide on α and γ iron. CSB (10)

Advantages of Bakelite Mounting Small Specimens. F. L. ROBBINS. *Metal Progress,* Vol. 29, June 1936, page 74. This type of mounting is superior to low-melting alloys in making possible a flat surface over the entire cross-section of the specimen and being resistant to most of the etching reagents. WLC (10)

New Technique for Obtaining X-ray Powder Patterns. R. A. STEPHEN & R. J. BARNES. *Nature,* Vol. 137, Mar. 28, 1936, pages 532-533. Explains points of difference between authors' method of reflection at small angles from a flat specimen, (*Nature,* Vol. 136, 1935, page 793) and Brentano's method (*Nature,* Vol. 136, 1935, page 988). CSB (10)

Fine Structure of the L_{23} Absorption Edge of Magnesium Metal. H. W. B. SKINNER & J. E. JOHNSON. *Nature,* Vol. 137, May 16, 1936, page 826. Measurements are given of the fine structure of absorption edges in the region of 100-300 A.U. X-rays, leading to data on energy levels of electrons in metals.

X-Ray Diffraction Study of Liquid Sodium. L. P. TARASOV & B. E. WARREN. *Journal of Chemical Physics,* Vol. 4, Apr. 1936, pages 236-238. The X-ray scattering curve for liquid Na was obtained photographically with Mo Kα radiation, monochromatized by reflection from rocksalt. The significance of the curve as giving a picture of a simple monatomic liquid is discussed. FPP (10)

Physical Changes in Steel During Hardening, Annealing, and Heat Treating (Beiträge zur Frage nach den Zustandsänderungen des Stahles beim Härten, Anlassen und Glühen) A. VON VEGESACK. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 227, May 12, 1936, pages 145-178. **(Bidrag till fragan om stalets tillstandsändringar vid härdning, anlopning och glödgning)** *Jernkontorets Annaler,* Vol. 120, Feb. 1936, pages 49-98. The steels used analyzed approximately 1.24%, 1.04% and 0.70% C, and had been hardened from temperatures of 800° to 1100° C. Annealing was carried out in 25° increments from 50° to 700° C. for 5 hr. periods. Heat treatment for 150 hrs. at 700° C. was carried out on the samples after the annealing series had been completed. The following results were noted. (1) Annealing from 75° to 125° C. causes a slight increment in the hardness. (2) The linear and cubical expansion show a maximum at 200°-250° C. which increases with the C content and the hardening temperature. The hardness shows either a maximum or minimum at the same point. (3) At 350° C. the linear and cubical expansions decrease. (4) At 600° C. they begin to increase again and more rapidly for the higher C contents and hardening temperatures. Where the increase is large, the hardness decreases more rapidly. (5) This increase is accompanied by a separation of C, which appears very markedly for the large changes as the stable system Fe-C, but only in microscopic amounts for small changes in the linear and cubical expansion. (6) The quantity of C separated is proportional to the time at which the hardened steels have been annealed between 25° and 400° C. prior to prolonged heating at 700° C. (7) C separation did not appear to take place except in steels which had been hardened. (8) The lamellar martensite is visible up to 600° C. It remains light in color and throws out little or no cementite at higher annealing temperatures. The austenitic base gradually decomposes at 525° C. to pearlitic granular structure. (9) On hardening hyper eutectoid steel at various temperatures from the homogeneous γ field, the specific volume increases with the hardening temperature. (10) The author concludes that martensite has no greater solvent power for C than other α iron, and that the chief condition for hardening is the separation of a highly dispersed C during the formation of martensite. Lower Sulphides of Cobalt. The Co-CoS Phase Diagram (Uber die Neideren Sulfide des Kobalts. Das Zustandsdiagramm des Systems Co-CoS) OTTO HULSMANN & FRIEDRICH WEIBKE. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 227, May 12, 1936, pages 113-123. WB (10)

Unequaled Versatility

● ● ● *an outstanding feature of the Leitz Panphot which although but recently announced has already attained wide acceptance and is gaining new adherents daily.*

The Leitz Panphot answers the need for a single instrument that can handle the ever increasing complexities of microscopical research problems. It's the most useful and versatile instrument with which the metallurgist's laboratory can be equipped.

Equally convenient for visual observation and photomicrography, it makes use of all of the following methods of illumination:

Transmitted Light **polarized or non-polarized**	**Reflected Light** **polarized or non-polarized**
Darkfield **in transmitted light**	**Darkfield** **in reflected light (Ultropak)**

These are but a few of its many useful features. They are fully described in Catalogue No. 7552. Shall we send you a copy?

Principles of Metallography. Robert S. Williams & Victor O. Homerberg. 3rd Edition. McGraw-Hill Book Company, New York, 1935. Cloth, 5½ x 8¼ inches, 313 pages. Price $3.50.

The purpose of this book is the presentation of the fundamentals of physical metallurgy and of laboratory metallography to the general reader. It is directed in particular to the student of engineering in divisions other than metallurgy. The third edition differs materially from its predecessors both in content and arrangement, a large part of the text having been rewritten and expanded and the 6 chapters having been rearranged into a more logical order.

The subject of phase diagrams is now treated in 2 consecutive chapters in an easily understood manner. Each type of alloy system is introduced by its characteristic thermal behavior, from which the constitutional diagram is developed. Real systems are used for illustrative material in most cases and the typical microstructures found are explained upon the basis of the diagrams involved. Only the cases of complete immiscibility, the eutectic, the solid solution, the congruently melting compound, the peritectic and the eutectoid are discussed, leaving the reader in danger of assuming that no other general types occur in alloy systems. There is a brief and none too clear presentation of the application of the phase rule to alloy diagrams. For the most part the material has been brought up to date, but a few of the diagrams remain in an obsolete form.

Non-ferrous metallography is covered in a single chapter of 45 pages. Even though the discussion is limited to the light alloys and those of Cu base, the emphasis being placed heavily upon the latter, it is necessarily highly condensed and consists chiefly in a listing of a few of the more important commercial alloys together with their mechanical properties, uses and typical microstructures. In addition short explanations of such fundamental properties of metals as work-hardening, slip, twinning and age-hardening are introduced. It is unfortunate that the phase diagrams of certain of the more common Cu base alloys are all that are given in this chapter, because there are others, notably in the field of light alloys that seem of equally great or greater importance. The new material added includes paragraphs on Mg and Cu-Be alloys, a section on corrosion and one on age-hardening.

The fourth and fifth chapters dealing with Fe and steel, as formerly, comprise the major portion of the volume. Here, in a conventional manner, is presented the Fe-C diagram together with a clear, though not fully modernized, exposition of the influence of composition, working and heat treatment upon the mechanical properties and microstructure of steels. The section treating the alloy steels has been completely rewritten and much new material has been added. Among the special alloys now discussed are those of Fe with Ni, Cr-V, Cr-Ni, Mo, Cr-Mo, Ni-Mo, W, Al, Cu and the high speed and stainless steels. Proportionally long sections are now devoted to cast irons, case hardening, the effect of impurities upon steel, and the corrosion problem. The second of the 2 chapters on Fe and steel is devoted to the technique of macroscopic examination. Many excellent photographs of typical macroscopic defects are included.

Laboratory methods of thermal analysis, microscopy, photomicroscopy, magnetic testing and X-ray analysis are treated in the concluding chapter. The section dealing with thermal analysis is little more than a running account of the usual type of procedure with too little attention devoted to the fundamentals of thermometry. The treatment of microscopy is generally superior to that found in most tests of this class. It is somewhat overburdened with pictures of the various makes of equipment, but includes a very helpful, though not exhaustive, explanation of the optics of the metallographic microscope. There is in addition a thoroughly satisfactory description of the preparation of metallographic specimens in which the newer techniques of mounting in plastics are mentioned. Only a few pages of general descriptive matter, of little help for laboratory directions, are devoted to the subjects of magnetic testing and X-ray methods. In an appendix there is given an outline of a brief laboratory course in Metallography, a greatly abridged list of commercial alloys and an extensive table of etching reagents.

In the course of revision much obsolete material has been eliminated, but the careful reader may still take exception to some of he statements remaining in the text. Only a few serious errors were found. Among these may be mentioned cooling curves with reversed curvature and supposedly "typical age-hardening curves" of a most abnormal sort. On the whole the book is excellently adapted to its purpose and its acceptance by the interested public is guaranteed by the success of the earlier editions. The printing is large enough to be comfortably read and the reproductions are excellent.

Macrographic Control (Control Macrografico) *Metalurgia y Construccion Mecanica*, Vol. 2, May 1936, page 1.

FRM (10)

Scale on Galvanizing Sheets (Die Zunderschicht auf Blechen zum Verzinken) H. Bablik. *Oberflächentechnik*, Vol. 13, June 2, 1936, pages 125-127. Origin and nature of scale are explained and the importance of correct pickling for hot galvanizing is pointed out, especially the difficulty of pickling sheets which are double for rolling, and of annealing of cold rolled sheets. In the latter process, a reduction of the scaled surface takes place by reaction of the C of the sheet with the O of the scale with the formation of CO; this scale structure is different from the scale formed in the rolling process which is pure oxidation. The amount of roll scale formed depends on the kind of Fe, composition of the oxidizing medium, oxidation temperature and duration and can be calculated from $W = K\sqrt{t}$, where W is the scale formed, K is a constant and t the duration of reaction. Curves are given. The composition of the scale has been determined by experiment:

Material	End temp. of rolling	Total scale	% Fe_2O_3	% Fe_3O_4	% FeO
Ingot iron	780° C.	0.013 mm.		60	40
Swedish Lanes iron	980° C.	0.035 mm.		20	80
Mild steel	980° C.	0.045 mm.	11	22	67
Staffs. wrought iron	1245° C.	0.036 mm.		11	89

As the FeO layer forms the principal part of the scale the pickling process has to attack this layer particularly.

The Beilby Layer. G. I. Finch & A. G. Quarrell. *Nature*, Vol. 137, Mar. 28, 1936, pages 516-519. Reviews history of attempts to determine nature of polished layers on metals, from 1665 to the Faraday Society Symposium on "The Structure of Metallic Coatings, Films, and Surfaces" of 1935. 27 references.

CSB (10)

Orientation in Peritectic Structures. Alden B. Greninger. *Nature*, Vol. 137, Apr. 18, 1936, page 657. Preliminary results from an X-ray study of the peritectic reaction $\alpha + \text{liquid} \rightarrow \beta$ in the Cu-Zn system prove that the orientations of the β crystals are definitely related to the α crystal orientations, the relation being that found for the decomposition of Fe-Ni by Nishiyama and Wasserman.

Crystal Plasticity (Kristallplastizität) E. Schmid & W. Boas. Julius Springer Verlag, Berlin, 1935. Paper, 5½ x 8½ inches, 373 pages. Price 32 RM.

This is the seventeeth monograph of the well-known series on the structure and properties of matter founded by Prof. M. Born and J. Franck.

The authors have summarized in very complete fashion the great amount of research done in recent years on the plasticity of crystals; by far the larger part of the book relates to metal crystals, and the book is therefore of interest primarily to metallurgists.

The material is treated under the following headings: crystallographic fundamentals; crystal elasticity; preparation of crystals; orientation determinations; geometry of the crystal deformation process; plasticity and strength of metal crystals—elements of translation and twinning, dynamics of translation, dynamics of twin formation, fracture along crystal faces, after-effects and reversed loading, change in physical and chemical properties on cold working, recrystallization; plasticity and strength of ionic crystals; theories of crystal plasticity and strength; explanation of the properties of polycrystalline technical metals upon the basis of the behavior of single crystals.

Although there had been work on the crystallographic mechanism of deformation of metal crystals as early as Osmond (and earlier), most of our present knowledge originated in the work done in the Kaiser-Wilhelm-Institut für Metallforschung by Schmid, Polanyi, Mark and others. This book includes all of this work and includes also work done elsewhere. Apart from Elam's book, which is much less complete, this is the only complete summary available of this field—a field which has caused the metallurgist many misgivings.

The study of the mechanical properties of metals is a field of rapidly increasing importance to the metallurgist, and the modern metallurgist may well pay close and studious attention to this excellent book. For those who are interested as intelligent students in the science of metals (may their tribe increase) this book will be a delight and a stimulation. While many metallurgists look askance at work on single crystals, and the difficult X-ray methods and geometric methods which it requires, a serious study of the properties of single crystals is of immense basic importance to the understanding of the behavior of industrial materials. The subject is a very wide one with infinite ramifications: the surprising thing about it is not the slowness with which the results of research have been applied to industrial problems, but the rapidity with which knowledge in the field has advanced. It has often been said that the material engineer has nothing to learn from the behavior of single crystals, that his needs are amply met by his knowledge of the behavior of materials in the condition used. There is, of course, a good deal of justification for this point of view though it is fearfully short-sighted. It seems necessary continually to repeat the principle, long since learned by physicists and chemists, that fundamental research has and will have in increasing measure a real practical outcome, and that such research has a practical result not seen in the cursory glance, a result consisting in an increasing knowledge of behavior leading to simpler and more correct modes of thought. The papers by Jeffries a decade ago on recrystallization and grain growth and on slip resistance—papers on the pure science of metals—have resulted in greatly improved efficiency in the thinking and thus the usefulness of the practicing metallurgists; is it extreme to say that they have been worth millions of dollars to the metallurgical industries? Books such as the present one serve such a purpose, and when admirably written, as this one is, are heartily to be welcomed.

The authors have presented not only a summary of the information available in the field, but have produced a working text, in which the geometric and crystallographic methods of analysis and the treatment of elastic theory are given in full detail, so that the book may be used as a handbook by anyone working in this field. It is, of course, not to be used by the beginner, but can readily be understood by those with training in crystallography, mineralogy, or modern physical metallurgy. Tables are given summarizing much of the data. photographs of deformed crystals are used to illustrate the text; X-ray photograms are produced to give graphic representation of preferred orientation.

The book is well printed and the diagrams and illustrations are attractively reproduced. If you would follow the course of one highly important branch of modern physical metallurgy you will have this book.

A bibliography of 703 references is appended.

CSB (10)

Influence of Supercooled Austenite on Thermal Treatment of Steel. N. P. Grechko & M. I. Korukov. *Metallurg*, Vol. 11, Apr. 1936, pages 3-16. In Russian. Results obtained with interrupted, isothermal, and usual quenching are compared for steels having the composition: 0.66% C; 0.38 C, 1.24 Cr, 3.42 Ni; 0.38 C, 0.84 Cr, 2.23 Cu; 0.34 C, 0.66 Cr, 2.92 Ni, 0.55 Mo, 0.15 V; 0.48 C, 1.85 Cr, 3.29 Ni, 0.31 V; 0.63 C, 2.15 Cr, 2.04 Ni, 0.43 Mo and 0.39 C, 1.90 Si, 0.83 Cr, 3.42 Ni, 0.76 Mo, 0.14 V. Physical properties studied showed that interrupted quenching gives the same results as the normal quenching, but reduces internal strains. Isothermal quenching produces in all steels tested a greater elongation and impact strength than straight and interrupted quenching. The ratio proportional limit-tensile strength is greater after straight and interrupted quenching than after isothermal in all steels tested with the exception of Cr-Ni-Mo-V steel. Cooling speed after 400°-500° C. soaking has a pronounced influence on the final hardness and mechanical properties of the metal, so that with interrupted quenching a cooling speed is obtained which is sufficiently slow for assuring stability of austenite during the second stage of transformation, 540°-300° C. 103 references.

Cohesion of Alkali Metals. Paul Gombás. *Nature*, Vol. 137, June 6, 1936, page 950. Theoretical calculations of heat of evaporation of K, Rb, and Cs have been made which agree with experimental values within 25% to 30%; the details will appear elsewhere.

CSB (10)

Temperature of Formation of the Metastable γ' Phase in Cu-Al Alloys and Its Dependence on Al Concentration (Temperatur der Bildung der Metastabilen γ' Phase von Cu-Al-Legierungen und ihre Abhängigkeit von der Al-Konzentration) V. Gawranek, E. Kaminsky & G. Kurdjumow. *Metallwirtschaft*, Vol. 15, Apr. 17, 1936, pages 370-371. Alloys of Cu with 12.9 to 13.5 weight % Al, with 0.1% increments, were quenched in an oil bath at 250° to 300° C., retaining the β for a short time, then the thermal curves measured when cooled in air from this temperature, and the resulting structures examined by X-rays. The thermal arrests fell on a smooth curve from 250° at 12.9% Al to 160° at 13.4% which is continuous with the earlier results for the β_1-β_1' transformation. The final structure of the 12.9-13.1% Al samples was $\beta' + \gamma'$; 13.2-13.4% showed γ' only. Experiments also showed the β_1-γ' transformation to be irreversible. These results are correlated with previously published information on these transformations.

11. PROPERTIES OF METALS AND ALLOYS

The Vapour Pressure of Red Phosphorus. H. W. MELVILLE & S. C. GRAY. *Transactions Faraday Society,* Vol. 32, July 1936, pages 1026-1030. The vapor pressure of red P was determined by evaporation in a vacuum. Application of the Herz-Knudsen effusion equation to the results gives values for the vapor pressure about 10^7 times lower than the normal static method. The new values are given by the equation

$$\log_{10} p \text{ (mm.)} = -\frac{4110}{T} + 1.1.$$

The reason for the discrepancy is due to P_2 molecules condensing on and evaporating from red P. PRK (11)

A. J. PHILLIPS, SECTION EDITOR

Copper-zinc-tin Bearing Metals (Lagermetalle auf Kupfer-Zink-Zinn Grundlage) F. HANSEN. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, June 27, 1936, pages 807-808. Bearing alloys with 59.9% Cu, 34% Zn, 4% Sn, 0.6% Si and 1.5% Ni; 78% Cu and 22% Sn; 83% Cu, 14% Sn, 2.5% Pb and 0.5% Ni; and 62% Cu, 30% Zn, 4% Sn, 2.5% Pb and 1.5% Ni were used satisfactorily particularly as bearings in machine tools, roll neck bearings, textile machinery and gears. They can be cast and do not show undue shrinking. The high Zn content is, contrary to previous views, not at all injurious. Melting temperatures for Cu alloys with 28-33% Zn, 3-5% Sn and some Pb and Ni should be 884°-908° C. Tensile strength is 25-35 kg./mm.², yield point 18-22 kg/mm.², elongation 20-10% and Brinell hardness 90-110. Tubes can be made from these alloys by extrusion. Ha (11a)

Thermal-Conductivity of Some Piston Alloys at High Temperatures (Über das Wärmeleitvermögen einiger Kolbenlegierungen bei höheren Temperaturen). F. BOLLENRATH & W. BUNGARDT. *Metallwirtschaft,* Vol. 15, Apr. 17, 1936, pages 368-370. An apparatus for the determination of thermal conductivity is described, in which errors due to radiation losses are reduced by means of auxiliary heating elements, so that measurements can be made up to 400° C. with an estimated error of 7%. Results are tabulated for 6 different Al piston alloys at 50° intervals from 50° to 350° C., all showing a constant temperature coefficient within this range. A forged alloy was superior to a cast sample of the same composition, the Al-Cu alloys were all better than the Al-Si alloys, and Mn lowered the conductivity appreciably. GD (11a)

Magnesium—Lead Alloys. K. V. PEREDELSKII. *Legkie Metallui,* Vol. 4, Dec. 1935, pages 43-48. In Russian. The addition of 1-20% Pb to Mg increases the tensile strength, hardness, and resistance to corrosion. These alloys can be cast and cold-worked. An alloy containing 3.87% Pb has a tensile strength of 16.4 kg./mm.² and an elongation of 7.9% in the cast condition. HWR (11a)

Alumag, Al-Mg Alloy Resistant to Corrosion (Alumag Alliage Aluminium-magnesium resistant à la corrosion) H. ROGEZ. *Métaux,* Vol. 10, Dec. 1935, pages 358-368. Mg forms with Al a solid solution which is homogeneous and stable at all temperatures for Mg content less than 14%. High resistance Alumag has resistance to rupture of 4 kg./mm.² and 27-30% elongation. GTM (11a)

The Bactericidal Action of Pure Metals and Metal Fillings. Mary S. Sheppard. *Dental Cosmos,* Vol. 77, Oct. 1935, pages 968-975. Information regarding the bactericidal action of metal fillings and the recurrence of caries adjacent to the fillings. Pure Au, Ag, Cu, Hg, gold and amalgam fillings were studied with reference to their action on cultures of L. acidophilus, Staphylococcus aureus, yeast, and mouth organisms. Pure Cu and Hg showed definite bactericidal properties; some of the gold and amalgam fillings showed bactericidal action, while others were slight inhibitors and still others showed no effect. Pure Au and Ag were without effect or even favored bacterial growth. Amalgam fillings, which had been removed from teeth with recurring caries, showed bactericidal properties. Thus the relation between bactericidal action and recurrence of caries was definite. 12 references. OEH (11a)

Electrical-Resistance Alloys of Copper, Manganese, and Aluminum. James L. Thomas. *Bureau of Standards Journal of Research,* Vol. 16, Feb. 1936, pages 149-159. An investigation has been made of the electrical properties of alloys containing from 4 to 15% Mn and from 0 to 10% Al, the remainder being Cu. An alloy containing 85% Cu, 9.5% Mn and 5.5% Al has properties very similar to those of manganin. Its thermoelectric power against Cu is much smaller than that of manganin and this thermoelectric power may be brought to zero by the addition of a very small amount of Fe. Resistance coils constructed from these alloys, with or without added Fe, have been very stable in resistance. By proper baking, their temperature coefficients of resistance at 25° C. may be made as nearly zero as desired, and this coefficient changes less with temperature than does that of manganin. WAT (11a)

Tellurium Lead. *The Dutch Boy Quarterly,* Vol. 14, No. 2, 1936, pages 9-11. Tellurium leead is practically pure Pb with only 0.1% Te or less, which, however, effects a marked change in physical structure in that it produces a finer and more uniform grain size. The resistance to corrosion, even under elevated temperatures and where vibrations are present is very high, and the tensile strength is claimed to increase when the metal is strained. Due to the acid resistant property the material is used for tank linings in the chemical industry and for pipes. It will stand hot H_2SO_3 and H_2SO_4 at 160°180° F. It can be worked as ordinary Pb. Ha (11a)

The Influence of Gases on Mercury Emulsions Prepared by Ultrasonic Waves. C. Bondy & K. Söllner. *Transactions Faraday Society,* Vol. 31, June 1935, pages 843-846. Hg is emulsified by ultrasonic waves in the same way as by shaking. The mechanism consists in the bursting of bubbles of the second liquid coated with thin films of Hg. Adsorbed gases stabilize Hg emulsions. The concentration of the emulsions formed in different liquids depends upon the stabilizing properties of the dispersion medium. 12 references. PRK (11a)

Beryllium-Copper Wire has unique Characteristics. J. Delmonte. *Wire & Wire Products,* Vol. 11, July 1936, pages 326-327, 355. Be-Cu with 2-2.5% Be is the highest strength Cu available after work-hardening and heat treatment at 800° C. with subsequent quenching. Curves show the effect of small Be additions on electrical conductivity which is markedly lowered, from 2 to 15%. The yield point of heat treated Be-Cu lies at about 135,000 lbs./in.², tensile strength at about 180,000 lbs./in.², and elongation (in 2") is 2-6%. Be-Cu is replacing phosphor bronze wire. If it is desired to soften Cu-Be wire for forming operations it is heated to 800° C. for about 1 hr. and immediately quenched in cold water. Such wires are used for weaving wire cloth. Ha (11a)

Deformability of Aluminum as Dependent on Purity (Beitrag zur Kenntnis des Formänderungsvermögens des Aluminiums in Abhängigkeit vom Reinheitsgrad) W. Helling. *Aluminium,* Vol. 18, July 1936, pages 307-309. Al rods of 99.3 to 99.977% purity were rolled and drawn and tensile tests made in different stages of the deformation. A table shows tensile strength, Brinell hardness, elongation at fracture, and reduction of area. Quite generally, the deformability of Al increases with increasing purity. Ha (11a)

The Casting and Treatment of Magnesium Alloys. A. J. Murphy. *Metal Industry,* London, Vol. 48, Jan. 17, 1936, pages 108-110. Author discusses in a general manner the foundry technique and heat treatment of some of the Mg-base alloys known as "Elektron A 8" and "A Z 91." This includes the approx. composition and physical properties. Corrosion resistance of Mg-base alloys, including results obtained in some laboratory tests, are considered. Some new applications of Elektron castings are mentioned. HBG (11a)

Manufacture of Sheet Silver. Mechanical Properties of Sheets of Commercial Silver Alloys as Dependent on Manufacturing Process (Die Herstellung von Silberblech. Die Festigkeitseigenschaften von Blechen technischer Silberlegierungen in Abhängigkeit von der Herstellungsart) H. Moser & E. Raub. *Mitteilungen des Forschungsinstituts und Probieramts für Edelmetalle,* Vol. 10, May/June 1936, pages 19-27. The effect which shape of casting, hot-forging, and oxide film have on the quality of Ag sheet was investigated. The tests were made with sheets of different fineness, and while definite conclusions could not be drawn the results showed that, in general, sheet made from flat bars of 835 fineness usually has a higher tensile strength and yield point but lower elongation than sheet made from round bars of the same fineness; the difference in quality disappears, however, with increasing degree of working. The same holds good for the 925 alloy for elongation, but the tensile strength was lower for hot-forged sheets than for rolled sheets. The oxide film from annealing did not exert a definite effect on mechanical properties as long as it was of usual thinness. Ha (11a)

Some Peculiarities of Electrolytic Metals (Quelques particularités des métaux électrolytiques) Ladislav Jenicek. *Revue de Métallurgie,* Vol. 33, June 1936, pages 371-378. Heavy electrolytic deposits of Cr, Ni, Cu and Fe were studied dilatometrically and by hardness determination. Hardness of the deposits is reduced with the drawing temperature which, in the case of Fe and Cr, is associated with contraction amounting to slightly less than 1%. The phenomenon is due to H removal. Best etching of Cr was obtained by using 30-40% boiling HCl in which Cr is made cathode. The action is completed in 5-8 seconds. After drawing to 1000° C. the hardness of Cr could be reduced to 230-250 Brinell. JDG (11a)

V. V. KENDALL, SECTION EDITOR

"4640" the Unknown. E. F. Davis. *Automotive Industries,* Vol. 75, July 18, 1936, pages 90-93. The medium C Ni-Mo steel, classified as S. A. E. 4640, has been found superior to any other oil hardening gear material by one leading gear company. A Ni content of 1.65-2.00% and Mo from 0.20-0.30% are preferred. High tensile properties, over 290,000 lbs./in.² ultimate, 180,000 lbs./in.² yield, and 10-12% elongation, are obtained, as well as Izod impact values of 5 to 6 ft.-lbs. This steel is also characterized by high fatigue resistance, a wide heat treating range, good surface hardness and minimum distortion in heat treatment. It is recommended for use in gears, transmission shafting, synchronizing collars, clutch shells, side plates, high tension bolts and the like. BWG (11b)

The Embrittlement of Alloy Steels. F. C. Lea & R. N. Arnold. *Proceedings Institution of Mechanical Engineeers,* Vol. 131, Nov.-Dec. 1935, pages 539-602. Researches to determine some of the conditions under which age embrittlement occurs due to stress and prolonged heating are described. It was found that steels with 3% Ni-1% Cr, with or without Mo, become embrittled under conditions of prolonged heating, whether stressed or unstressed. Embrittlement may occur with very little change in other properties. A theoretical investigation of tensile stresses in a necked tensile specimen is attempted to explain tensile stress fractures in embrittled steels. Tests and apparatus used are described. Ha (11b)

Alloys of Iron and Beryllium (Les Alliages de Fer et de Glucinium) J. Laissus. *Revue de Fonderie Moderne,* Vol. 30, Apr. 10, 1936, pages 121-123. Development of production of Be, its properties and present uses are briefly discussed. While Be alone does not seem to give to steel particular properties, the mechanical properties of alloy steels seem to be noticeably improved in presence of Ni and Cr simultaneously. An antimagnetic Ni-Mo steel with 1% Be was obtained. Ha (11b)

Austenitic Stainless Alloys; Their Properties and Characteristics. V. N. Krivobok & R. A. Lincoln. *Steel,* Vol. 98, May 11, 1936, pages 68. Abstract of paper read before interchapter meeting of American Society for Metals at Pennsylvania State College, May 1-2. Austenitic alloys which are fairly easy to decompose will have properties differing from those austenitic alloys in equilibrium. Manner of decomposition is of no consequence. By adjusting ratio of alloying elements, certain combinations of physical properties could be obtained which could not be found in alloy of another composition. Physical properties of these types of alloys bear no definite relation to their surface hardness. Original gives results of tests of effect of concentration of alloying elements on physical properties. MS (11b)

Replacement of Tungsten Magnet Steel with Chromium Steel Containing Molybdenum or Manganese. G. G. Livshitz & N. Ya. Drozdov. *Kachestvennaia Stal,* Vol. 4, No. 1, 1936, pages 56-61. In Russian. Steels containing: 1.00% C, 1.50 Mn, 8.16 Cr, 0.20 Si; 1.07 C, 0.34 Mn, 1.76 Mo, 9.68 Cr, 0.23 Si; 1.02 C, 2.28 Mn, 2.95 Mo, 2.53 Cr, 0.03 Si were investigated for their magnetic properties after different heat treatments. Magnetic properties obtained are calculated with the omission of demagnetizing factor of specimens. The steel with 1.0 C, 1.5 Mn and 8.0 Cr after oil quenching from 1175°, drawing for 1 hour at 600° and requenching in oil from 900° C. has $B_r \times H_c = 72 \times 10^4$ and steel with 1.0 C, 1.76 Mo and 9.7% Cr after quenching from 950°-1000° C. in oil has $B_r \times H_c = 74 \times 10^4$ which is equal to values obtained with W steels or slightly better. (11b)

Hot Working and Properties of Heat Resistant Cr-Mo Steel with an Increased Si Content. P. B. Mikhailov-Mikheev & A. I. Chishik. *Metallurg,* No. 2, 1936, pages 35-54. In Russian. A comprehensive investigation of steels having composition: 0.59% C, 0.60 Si, 14.6 Cr, 1.95 Mo; 0.60 C, 0.71 Si, 16.5 Cr, 1.65 Mo; 0.75 C, 0.90 Si, 17.0 Cr, 1.67 Mo. Their hot working characteristics, structure, mechanical properties, critical points, corrosion resistance, scaling resistance, strength at elevated temperature and fatigue resistance were studied. After quenching at 1050° C. and drawing, average tensile strength was 80-85 kg./mm.², yield point 55-60 kg./mm.², elongation 18-24%, reduction of area 45-55%, impact strength 2 kgm./cm.²/min. were obtained. These steels have chemical resistance equal to the usual Cr stainless steel but have a better scaling resistance than both 17% Cr and 14% Cr-1.5% Mo steels. It has a better fatigue limit and strength at elevated temperatures than 17% Cr stainless steel and sufficiently high ductility both in cold and hot states. Carbides, liquation and segregation are its drawbacks, which can be overcome by proper heat treatment. The steel is fully free from intercrystalline corrosion, not having any austenitic phase during usual heat treating operations. It might be used for heavily loaded parts operating at elevated temperatures. (11b)

Tungsten and Titanium Carbides (Les carbures de tungstène et de titane) *Journal du Four Electrique,* Vol. 45, June 1936, pages 200-201. This article erroneously states that stellites invented by Haynes are made by sintering tungsten carbides with Co at very high temperatures, since stellites are cast from the molten stage. Usual stellites have a composition: 1-4% C, 5-25% W, 20-25 Co, 20-30 Cr. They were further improved into a product containing 3.2-6% C, 83-97% W, 6% max. Co and are sold under the trade names of Widia, Carboloy, Titanit, etc. JDG (11b)

Steel Manufactured in France (Les Aciers de Fabrication Francaise) *Science et Industrie (Mecanique),* Vol. 20, Jan.-Feb. 1936, pages 38-41; Mar.-Apr. 1936, pages 54-62. The first installment discusses non-magnetic steel, and steels having a high permeability and low hysteresis. The second section deals with high elastic limit steels. All are discussed as to: (1) composition, (2) physical and mechanical properties at room and high temperature, (3) heat treatment, (4) corrosion resistance, (5) machining, (6) applications and (7) trade marks. FR (11b)

Influence of Casting Temperature and Cooling Speed on Mechanical Properties of Low Silicon Iron Castings. V. Ya. Romasheva. *Liteinoe Delo,* Vol. 7, No. 5, 1936, pages 28-32. In Russian. Cast Fe having aa composition 3.6-3.9% C, 0.8-1.2 Si, 0.6-0.9 Mn, 0.8 S max., 0.1-0.25 P was cast in green sand, dried and preheated molds and studied microscopically and by determination of physical properties. (11b)

Steel for Autoclaves. R. J. Sarjant & T. H. Middleham. *Iron & Coal Trades Review,* Vol. 133, July 3, 1936, page 11. The following results are reported from investigations into the behavior of steel for autoclaves. Mild steel suffered severe intergranular cracking at even comparatively low temperatures (325° C.) when the H pressure was 250 atm.; at 125 atm. the attack was greatly reduced. 2½% Cr steel withstood attack up to 550° C. and under 125 atm. but the steel was embrittled. 1% Cr-V steel was not severely attacked at 325° C. and 250 atm. At 550° C. embrittlement took place, but H caused, at 125 atm., only slight decarbonization. Cr-Al-Mo steel was unaffected by H up to 550° C. at 125 atm. and showed little embrittlement. Ni-Cr-Mo steel, under 250 atm., showed only slight H attack at 550° C., but severe attack at 750° C. Cu-Cr-Mo steel was immune from any deterioration up to 550° C. and under 250 atm., but serious intergranular cracking took place at 750° C. 6% Mn-Co steel was free from attack by H but suffered embrittlement at 450° and 550° C. under 250 atm. 13% Cr steel was entirely free from H attack under most extreme conditions but showed some slight embrittlement at 325° and 550° C. The more highly-alloyed austenitic steels did not indicate any H attack or embrittlement up to 750° C. Ha (11b)

Gases in Steel. T. Swinden. *Iron & Steel Industry,* Vol. 9, Dec. 1935, pages 100-106. Paper read before the Newport & District Metallurgical Society, Nov. 1935. It is probable that gases in themselves or gas reaction products, together with a control of the grain size are the determining factors in explaining most of the hitherto unexplained differences between steels of similar type (and similar ordinary analysis) on the one hand and between steels made by different processes on the other. The effect and methods of determination and control of O content are discussed. The effect of passing various gases such as H, N, H followed by N, CO_2 and CO, through liquid steel is reported. It is concluded (1) that the solid solubility of N and CO_2 is not seriously lower than the liquid solubility, and these gases are apparently inert under the experimental conditions recorded, (2) the solid solubility of H is considerably less and that of CO slightly less than the liquid solubility. CMS (11b)

An Investigation of Abrasion in Cast Iron. Masuhiro Suzuki. *Science Reports Tohoku Imperial University,* Vol. 24, Feb. 1936, pages 724-744. Measurements were made of the relative abrasion of gray cast Fe of different chemical composition and of samples that were cooled at various speeds, using apparatus previously described by the author (Vol. 17, No. 3, 1928). Abrasion of gray cast Fe was found to be affected by the composition but not much affected by the tensile and hardness properties. P caused the greatest increase in resistance to abrasion. Combined C tended to increase the abrasion resistance, especially when it was higher than 1.3%. Mn and S had little effect; Si and total C had only an indirect effect by influencing the amount of combined C present. A critical pressure was found to exist, above and below which the amount of abrasion differed considerably. The following equation is given for the relative abrasion of both C steels and cast irons: $W_{nm} = K \frac{W_{Nm}}{W_{Nn}}$ and $K = a\mu^2$. The symbols n, m and N represent any substance contained in cast irons or the C content of C steels. W_{Nm} = standard specific abrasion of a substance, m, with respect to a standard substance N. W_{Nm} = same as above for substance n. W_{nm} = relative specific abrasion between substances m and n. μ = coefficient of friction. a = constant, invariable for a series of substances having similar properties but varies when their properties differ widely. BWG (11b)

Nickel Plated Steel Sheets for the Chemical Industry (Nickelplattierte Stahlbleche für die chemische Industrie) B. Trautmann. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, June 20, 1936, pages 785-787. Properties of steel sheets which are plated on one or both sides (by rolling on) with layers of Ni, Monel metal and austenitic Cr-Ni steel of about 5-10% of the total thickness are discussed. The sheet is usually a mild steel of 32-50 kg./mm.^{2} tensile strength. The plated sheet shows an average of about 40 kg./mm.^{2} and elongation at rupture about 25%. The corrosion resistance is determined entirely by the plating; Ni and Ni containing alloys are practically proof against lyes, inorganic and organic acids, salts and salt solutions and food stuffs. Cold working can be done as with the unplated steel; the plated layer should be laid face upwards for protection from mechanical injuries. Annealing, if necessary, should take place between 870° and 930° C. for 1-3 min. Welding should be done with pure Ni electrode. Fields of application for such sheets are described. Ha (11b)

Carbon and Low-alloy Steels. E. F. Cone. *Steel,* Vol. 98, Mar. 9, 1936, pages 43, 45. Abstract of paper read before the American Society for Testing Materials. See *Metals & Alloys,* Vol. 7, Mar. 1936, pages 77-84. MS (11b)

Effect of Carbon, Oxygen and Grain-Size on the Magnetic Properties of Iron-Silicon Alloys. T. D. Yensen & N. A. Ziegler. *Transactions American Society for Metals,* Vol. 24, June, 1936, pages 337-358. Data presented at Chicago Convention of the Society, 1935, on these relations indicates that O_2 is without appreciable effect at low densities but does have an effect on the high density permeability of Fe-Si alloys. Effect of C is generally less and the effect of grain size generally more than previously indicated. Effect of various forms of C is confirmed. WLC (11b)

Tensile Strength and Brinell Hardness of Cast Iron (Zugfestigkeit und Brinellhärte von Gusseisen) A. Leon. *Zeitschrift Verein deutscher Ingenieure,* Vol. 80, Mar. 7, 1936, pages 281-282. The reliability of formulae for the determination of certain properties of cast Fe from one other characteristic value, e.g. tensile strength from Brinell hardness, or compressive from tensile strength, is discussed on the basis of a compilation of formulas developed by several authors and found to be of doubtful value. One single characteristic figure of cast Fe alone will not permit defining other properties reliably. 11 references. Ha (11b)

Beryllium-Iron Alloys. W. Kroll. *Metals & Alloys,* Vol. 7, Jan. 1936, pages 24-27. 11 references. 1% Be allows hardening of 18-8 stainless up to a Brinell of 675. Discusses Be as a desulphurizer of much greater power than Ca. WLC (11b)

Modern Developments in Stainless Steels. J. H. G. Monypenny. *Metal Treatment,* Vol. 2, Spring 1936, pages 24-28, 33. Martensitic stainless steels, which can be hardened and tempered, are used for cutlery, and have moderate corrosion resistance. They originally contained 0.3% C and 12-14% Cr. Greater corrosion resistance is obtained with 18% Cr plus 2% Ni. Ferritic steels (stainless Fe), used for fabrication, have up to 14% Cr and a minimum of C. If Cr is increased to 20%, improved corrosion resistance is obtained but only at the expense of notch toughness and a tendency to grain growth. Addition of Cu, however, increases the toughness. Ferritic steels with up to 30% Cr have good heat-resisting properties even in sulphurous gases. Austenitic steels with 18% Cr and preferably 8.5% Ni have very good corrosion resistance and are ductile. "Weld-decay" of 18:8 steels, and its partial prevention by keeping C below about 0.06%, by "stabilising" at 900° C (preferably after cold working), or by additions of Ti, Si, or Co are discussed. Additions of 1.5 to 2% of Si are not oxidized away during welding, increase corrosion resistance to acids, and are preferred. JCC (11b)

Heat Resisting Cast Irons. J. G. Pearce. *Metal Progress,* Vol. 29, Jan. 1936, page 63. Calls attention to appearance of description of 5.5% Si, 10% Al, 2.5% C Fe in *Journal Iron & Steel Institute,* Vol. 125, 1932, pages 392-426 and of the austenitic cast Fe in same journal, Vol. 126, 1932, pages 301-322, also *Transactions American Foundrymen's Association,* Oct. 1933, page 261. This was prior to Thyssen's investigation described by Portevin, *Metal Progress,* Vol. 28, Nov. 1935, pages 67-68. WLC (11b)

The A-B-C of Corrosion and Heat Resistant Steels. F. M. Palmer. *Metal Progress,* Vol. 29, Feb. 1936, opposite page 48. Tabulation of various properties of martensitic, ferritic and austenitic steels for these services. WLC (11b)

Chromium Cobalt Magnet Steel with Low Cobalt Content. V. A. Erakhtin. *Kachestvennaia Stal,* Vol. 4, No. 1, 1936, pages 49-55. In Russian. A steel with 0.95% C, 5.80 Cr and 6.05 Co was investigated. Deterioration in magnetic properties occurs as a result of carbide decomposition which does not take place under 700° C., but is pronounced between 700° and 1100° C., the maximum being at 800° C. Optimum quenching temperature is 950° C., but the time must not be too long, 5-10 minutes being the proper range. Any previous deterioration can be remedied by heating to 1180°-1200° C. followed by rapid cooling. After a proper treatment the steel gives $H_c = 90 — 100$, $B_r = 9500 — 8500$. (11b)

Progress in Special Steels. Robert Hadfield. *Blast Furnace & Steel Plant,* Vol. 24, Mar. 1936, pages 221-223; Apr. 1936, pages 308-309. Part of a paper read before the 7th International Congress of Mining, Metallurgy and Applied Geology. See "Recent Advances in Alloy Steels," *Metals & Alloys,* Vol. 7, July 1936, page MA 368L/1. The Production of Specially Hard Cast Irons for Alloying and Heat-Treatment. W. T. Griffiths. *Proceeedings Institute of British Foundrymen,* Vol. 27, 1933-1934, pages 563-587. See *Metals & Alloys,* Vol. 6, Mar. 1935, page MA 120. CEJ (11b)

Method for Comparing Properties of Heat Treated Structural Alloy Steels (Méthode de comparison des caractéristiques mécaniques des aciers spéciaux de construction traités) Francois le Chatelier. *Revue de Métallurgie,* Vol. 33, May 1936, pages 338-344. Proposes methods for comparison of alloy steels from the standpoint of their physical properties in which ratios of physical properties such as tensile strength-ductility ratio, etc., are considered rather than single characteristics. JDG (11b)

Stainless Steels and Weld Decay. H. Bull. *Sheet Metal Industries,* Vol. 10, Mar. 1936, pages 251-253. From a paper before the Royal Aeronautical Society in Manchester. Discusses the development of stainless steels. Methods of controlling the tendency to "weld decay" are treated. These are, reducing the C to 0.07% or less, adding about 1.0% W, adding about 0.6% Ti or V, or adding about 2.0% Si. AWM (11b)

Influence of Grain Size and Alloying Elements on the Quality of Steel. E. C. Bain. *Kachestvennaia Stal,* Vol. 4, No. 1, 1936, pages 23-34. In Russian. A translation of paper presented at Moscow. A summary of results already published. (11b)

Some Forging Copper Steels Susceptible to Structural Hardening (Quelques aciers de forge au cuivre susceptible d'un durcissement structural) L. Faure. *Revue de Métallurgie,* Vol. 33, May 1936, pages 331-337. In Cu bearing steels Cu precipitates from solid solution and rapidly coalesces at 650° C. On heating in an oxidizing atmosphere it accumulates on the surface of the metal under the scale and at a temperature above 1100° C. diffuses along grain boundaries causing red shortness. Cu-Cr-Fe alloys with Cu more than 0.6 and Cr around 0.5% behave as Cu steels. Ni additions raise melting point of Cu inhibiting the intergranular penetration of Ni-Cu alloy. Cu goes into solution in Cu-Cr and Cu-Ni steels of this composition between 680° and 750° C. In order to produce precipitation hardening cooling between 680° and 615° C. has to be at least 100° C. per hour. Precipitation hardening by drawing at 500° C. produces an increase in elastic limit, tensile strength and elastic limit curves being directly proportional to Cu content. The speed of reaching a maximum strength increases up to 0.7% Cu, the minimum content practical for commercial use. About 10 kg./mm.^{2} strength increase can be produced by these means. The method helps to obtain high elastic limits in annealed steels by using high Cu metal. JDG (11b)

Mechanical Properties of Muntz Metal LS-59 in Relation to Copper Content. P. I. Gradusov. *Tzvetnuie Metallui,* May 1935, pages 103-112. In Russian. Experiments were made on several compositions of Muntz metal with Cu varying from 57 to 61%, and Pb from 0 to 1%. Data are given illustrating effect of composition, treatment, hot and cold working, degree of reduction, etc. on the structure and mechanical properties of the alloys. BND (11b)

Effect of Iron Impurities on the Annealing of High Brass. W. A. Gibson & J. H. Doss. *Industrial Heating,* Vol. 3, July 1936, pages 443-446. The effect was studied at temperatures from 600°-1200° F. and for Fe impurities from 0.008-0.287%. Experiments and results are described in detail from which it is concluded that Fe impurities up to 0.09% are not harmful to annealing, that between 0.09 and 0.118% a great discontinuity occurs, and that presence of Fe greater than 0.118% is not harmful to sheet brass if properly manufactured and annealed under correct conditions. Ha (11a)

Making Tubing of High Strength Light Alloys. M. I. Kovarski. *Metallurg,* Vol. 11, June 1936, pages 96-101. In Russian. A series of experiments of adjusting composition and heat treating cycles resulted in an alloy which has 47 kg./mm.^{2} tensile strength and 10% elongation after being formed at 440°-460° C. and quenched at 505° ± 3° C. Its composition is: 4.6-6.0% Cu, 0.8-1.2 Mn, 0.65-1.5 Mg, 0.7 Si max, 0.5 Fe max. and 0.2 Ti max. (11a)

The Effect of Oxygen on the Clean Up of Phosphorus Vapour by Tungsten Filaments. H. W. Melville & S. C. Gray. *Transactions Faraday Society,* Vol. 32, July 1936, pages 1020-1025. Covering a filament with a layer of O atoms completely inhibits the dissociation of P_4 molecules upon it. It appears that the dissociation on a partially oxidized filament occurs wholly on the clean W surface. Measurement of the half-life for the P_4 — O_2 reaction and for the P_4 clean up shows the former to be much slower. In the P_4 — O_2 reaction, the W surface is covered with a layer of P on top of which are O atoms or molecules. 6 references. PRK (11a)

Alloying Aluminum. M. I. Zakharova. *Metallurg,* No. 2, 1936, pages 92-101. In Russian. Effect of different alloying elements on Al. Generalization of the mechanism of their action taken from literature. (11a)

Static Mechanical Properties of the German Standardized Tin Bronzes (Phosphorbronzes) in Cast (both as Cast and Annealed) State at Room Temperature and Elevated Temperatures (Die statischen Festigkeitseigenschaften der deutschen, genormten Zinnbronzen (Phosphorbronzen) in gegossenem (ungeglühtem und geglühtem) Zustand bei Raumtemperatur und Höheren Temperaturen) W. Claus & C. Goetzel. *Giesserei,* Vol. 23, Mar. 27, 1936, pages 154-158; Apr. 24, 1936, pages 206-219. The standard Sn bronzes WB_z6, GB_z10, GB_z14 and GB_z20 were studied in the as cast state and after annealing; the change in chemical analysis was determined in several stages. The Sn content of the 4 samples was 5.45, 9.09, 13.9 and 19.95% respectively, remainder Cu and 0.012-0.038% P. Bronze WB_z6 shows no difference in mechanical properties between as cast and annealed specimens. GB_z10 and, for all practical purposes, also GB_z20, behaved similarly. GB_z14, however, had in the as cast state, at room temperature low tensile strength and elongation. Elasticity modulus and Brinell hardness were higher in the as cast than in the annealed specimen. All properties decrease with increasing temperatures, both for the annealed and as cast state. The effect of using scrap in preparing casting is discussed. Results of all tests are recorded in 3-dimensional diagrams. 9 references. Ha (11a)

Influence of Additions on Properties of Magnesium Alloys. N. V. Ageew, M. I. Zamotorin & D. N. Shoykhet. *Metailurg,* No. 3, 1936, pages 27-47; No. 4, 1936, pages 4-59. In Russian. Influence of additions to Mg alloys containing respectively: 9.85% Al, 0.15 Mn, 0.09 Fe, 0.02 Cl; 6.03 Al, 2.98 Zn, 0.18 Mn, 0.02 Fe, 0.02 Cl and 10.14 Al, 1.04 Cu, 0.04 Si, 0.02 Fe, 0.03 Cl in the cast state and those containing 4% Al, 3 Zn, 0.2 Mn; 6 Al, 1 Zn, 0.2 Mn and 1.5 Al, 4.5 Zn, 0.75 Cu in rolled state were studied. Above alloys were melted in Fe crucibles under 30% KCl-70% $MgCl_2$ flux with the addition of proper elements cast into chills heated to 200° C. and the ingots split longitudinally. One half was aged, another used for physical testing as cast. Specimens of rolled stock were prepared by rolling these ingots into 3 mm. sheets. They were studied in "as rolled" state. Si increases gas absorption, liquation and shrinkage. It hardens and embrittles the alloys helping simultaneously the aging process. Mechanical characteristics of alloys change with temperature inversely proportionally to Si content. Fe can dissolve in these alloys up to 0.2% decreasing shrinkage. Hardness and strength are raised by it though it has no effect on aging and rolling properties. Na up to 1% decreases shrinkage, decreases strength both at room and elevated temperatures, particularly impact strength. It increases porosity and does not have any effect on aging. Na has the most pronounced deleterious influence on mechanical properties of these alloys, 0.9% Na reducing ductility to zero, and greatly lowers tensile strength. With 0.06-0.09% Na metals are hot short. It reduces aging. K lowers mechanical properties but has no influence on rolling and aging characteristics. Ca is a good deoxidizer and its presence up to 1% does not have a pronounced influence on mechanical properties. Magnesia reduces liquation, shrinkage and crystallization. With its content up to 0.1% almost no changes in physical properties are observed. When it passes this limit all mechanical properties drop. MgO does not affect aging. (11a)

The Catalytic Decomposition of Hydrogen Peroxide on Different Metals. Joseph Weiss. *Transactions Faraday Society,* Vol. 31, Nov. 1935, pages 1547-1557. The initial process of the catalytic decomposition of H_2O_2 by metals involves an electron transfer from the metal to H_2O_2 adsorbed on the surface. The radicals OH or HO_2 are formed and the chain reaction of the catalysis proceeds. The catalytic decomposition on Pt, Au, Pd, Ag and Zn has been investigated in detail. 20 references. PRK (11a)

Electrode Dispersion of Noble Metals. Andr. Voet. *Transactions Faraday Society,* Vol. 31, Nov. 1935, pages 1488-1491. When electrodes of noble metals are electrolyzed with a high current density and a high potential difference in alkaline, acid, and neutral solutions, a disintegration of the anode occurs with the formation of unstable suspensions. Such dispersion is accompanied by frequent pulsations. To obtain electrode disintegration for every potential difference a minimum concentration of electrolyte is required such as, .3 *N* H_2SO_4 and .2 *N* $(NH_4)_2SO_4$ for Au at 110 volts, 1.5 *N* H_2SO_4 for Pt at 110 volts. The electrode dispersion may be explained as the result of the repulsion of a periodically formed oxide layer on the surface of the anode. The Wehnelt effect, which is a sudden fall of the strength of current to about 1/10 value accompanied by small sparks and peculiar crackling, is not the cause of the electrode dispersion. 6 references.

OFHC
REG. U.S. PAT. OFF.

OXYGEN-FREE HIGH CONDUCTIVITY

A Superior Copper for All Purposes

OFHC Copper conforms to the A.S.T.M. Specification for electrolytic copper wirebars, cakes, etc., B5-27 with regard to metal content and resistivity, and is free from cuprous oxide.

OFHC Copper is characterized by its freedom from casting defects and its bar-for-bar uniformity. Its freedom from oxygen results in great ductility and toughness as evidenced by its high reduction of area and resistance to impact.

OFHC Copper withstands more working in hard condition when tensile strength is greatest, making it especially suited for products subjected to severe fabricating or service conditions.

Copies of a schedule of weights and dimensions of **OFHC** wirebars, cakes and billets, and a booklet containing technical information will be gladly furnished upon request.

On the Longitudinal Magneto-Resistance Effect at Various Temperatures in Nickel-Copper Alloys. Hakaru Masumoto & Yuki Shirakawa. *Science Reports Tohoku Imperial University,* Vol. 25, Apr. 1936, pages 104-127. Resistance changes of Ni-Cu alloys were measured at temperatures from —195° to 400° C. up to 1600 oersteds. Form of magneto-resistance-temperature curve was found to be the same as that of Ni; however, the resistance change of Ni was found to increase by addition of Cu, rapidly at first to a maximum (most pronounced at low temperatures) then to decrease until axis of concentration was crossed. Intensity of magnetization of Ni decreased steadily by Cu additions, becoming zero at the concentration point where a change took place from ferro to para-magnetic state. BWG (11a)

Magnesium and Ultra Light Alloys (Le Magnesium et les Alliages Ultra-Legers) Henri Portier. *La Technique Moderne,* Vol. 28, May 1, 1936, pages 313-320; June 15, 1936, pages 435-439. (1) Forging of Mg alloys is explained and works of de Fleury, Gris and Precoul are discussed. (2) Drop forging is said to be easy with Mg alloys. (3) Rolling must be thoroughly controlled. Reductions which are initially about 25% must later be decreased. Zn improves ductility of Mg alloys. Some alloys containing Cd are easily rolled. Al additions increase strength of alloys. Al + Ce additions give alloys of medium strength but of high ductility. (4) Extrusion is the only practical process for manufacturing bars, tubes and profiles with Mg alloys, and is performed at a low temperature (320° C.). (5) Bending and shaping of Mg alloys: It is good practice to anneal sheets at 300° C. Cold working is not advocated, shaping is preferably between 270° and 320° C. (6) Riveting is done cold with Al alloys containing 5% Mg. (7) Welding: torch welding is done without difficulty. Chief point is to avoid flux entrapments in the welds. Electric arc and spot welding can also be used. (8) Machining of Mg alloys is very easy: angle of cutters and other particulars are given for each type of machining. Second section of paper is very theoretical and is devoted to study of mechanical strength. Formulas and graphs are given. The second article deals with applications of Mg alloys. (1) Chemical applications: Mg is widely used in other alloys such as duralumin and Y alloy. (2) Physical or mechanical applications: most valuable property of Mg alloys is low density and applications are numerous where minimum weight is desired. (a) Aircraft engineering: typical parts made of Mg alloys are motor crankcases, pistons, screw propellers, landing devices, tanks, brake jaws, wheel stream lined casing, bearings, levers, doors, window-frames, etc. (b) Automobile and bicycle industries; typical parts made of Mg alloys are: motor crankcases, rear-axle casings, tanks, wheels, and numerous accessories. In light car construction Mg alloys are not yet used owing to their high price. (c) Other industries: Mg alloys are used in textile, electrical, radio, railway industries, etc. FR (11a)

The Determination of the Viscosity of Liquid Gallium Over an Extended Range of Temperature. K. E. Spells. *Proceedings Physical Society,* Vol. 48, Mar. 1936, pages 299-311. The viscosity of Ga, determined by a quartz capillary viscometer made to fit inside a tubular furnace, was found to vary from 0.02037 poises at 30° C. to 0.005783 at 1100° C., following Andrade's equation closely. All measurements were made *in vacuo.* By introducing a little dilute HCl before evacuation, the tendency of Ga to stick to quartz was overcome. JCC (11a)

12. EFFECT OF TEMPERATURE ON METALS AND ALLOYS

L. JORDAN, SECTION EDITOR

The abstracts in this section are prepared in co-operation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

Embrittlement of Alloy Steels Caused by Long Heating. A. M. Borzdika & S. I. Wolfson. *Kachestvennaia Stal,* Vol. 4, No. 2, 1936, pages 17-24. In Russian. Heating at 400°, 500°, 600° and 700° C. for 500 hours followed by heating to the temperature for a day and keeping at room temperature for a day repeated 82 times (4000 hours) was applied to the following steels: (1) 0.10-0.17% C, 3.40-4.00 Ni. 0.75-1.10 Cr; (2) 0.40-0.50 C, 0.20 Ni, 1.0-1.5 Cr; (3) 0.13 C, 5.8 Cr; (4) 0.16 C, 5.6 Cr, 0.65 Mo; (5) 0.2 C, 5.75 Ni, 19.2 Cr. Embrittlement was determined by microscopic examination, hardness determination and Charpy impact testing. C-Cr steel did not show embrittlement between 375°-615°. Ni-Cr showed distinct brittleness after heating at about 500° C., but heating at 600° C. increased its toughness. The 6% Cr steel heated around 500° C. gave exceptionally scattered results, though continuous heating at 600° C. lowered the original toughness but little. Addition of Mo to this steel eliminated the influence of heating on its toughness. Embrittlement is not directly connected with changes in hardness, nor is there any relation between microscopic appearance and embrittlement. Austenitic steels became brittle after even comparatively short heating at above 400° C. (12)

Industrial Experience Regarding Strength of Steels Permitting High Superheat (Experience industrielle sur la résistance des aciers permettant d'atteindre de très hautes surchauffes) Jean Dauvergne. *Revue de Métallurgie,* Vol. 33, May 1936, pages 325-330. A boiler installation is described in which different types of steel were used for superheater tubes. The compositions were: 0.47 Cr, 0.44 Mo; 0.41 Cr, 0.44 Mo, 0.75 Al; 5.25 Cr, 0.60 Mo; 4.86 Cr, 0.66 Mo, 0.57 Al; 10.62 Cr, 0.27 Mo, 0.97 Al; 15.35 Cr, 7.82 Ni. Visual examination after 10,000 hrs. at 560° C. and with speed of steam 11.6 m./sec. showed that all tubes withstood this service satisfactorily. JDG (12)

Some Experience in Developing Creep Testing Methods. P. B. Mikhailov-Mikheev & G. M. Denisov. *Metallurg,* No. 3, 1936, pages 47-60. In Russian. Mechanical features and experimental procedure adopted for the only creep testing installation in Russia. Metropolitan-Vickers type of design was adopted, but the installation was not operated long enough to warrant definite conclusions. (12)

2 **Determination of Creep Strength (Ermittlung der Dauerstandsfestigkeit)** H. Schmitz. *Zwanglose Mitteilungen des deutschen und oesterreichischen Verbandes für die Materialprüfungen der Technik* No. 28, May 1936, pages 409-412. The methods used for determination of creep strength are discussed with regard to their practicability; in order to be used in routine practice they should be simple and convenient in the normal operation of a plant, the time must be not longer than 50 hrs. under normal load, and the evaluation of the test results must not be complicated and give no ambiguous values. Practices developed in different countries and the regulations adopted are reviewed. A few examples illustrate satisfactory tests. Ha (12)

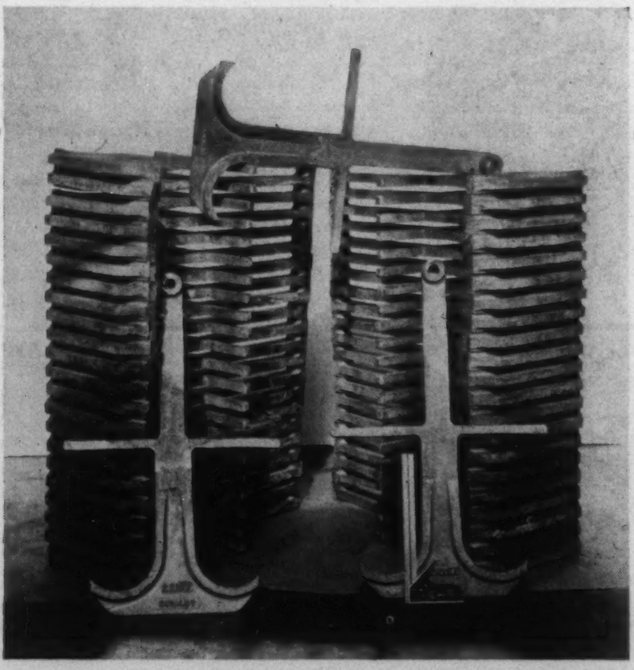
The Utilization of Creep Test Data in Engineering Design. R. W. Bailey. *Proceedings Institution of Mechanical Engineers,* Vol. 131, Nov.-Dec. 1935, pages 131-269; discussion, pages 269-349. Experimental data were obtained from the creep of Pb and steel tubes under compound stress in order to provide a rational basis for the design of parts operating under creep conditions. The theories involved are developed and distribution of stress and creep under compound stress determined in rotating disks and other important engineering parts. See also *Metals & Alloys,* Vol. 7, May 1936, page MA 261L/6. Ha (12)

4 **Some Tests of Tin Bronzes at Elevated Temperatures.** J. W. Bolton. *Foundry Trade Journal,* Vol. 54, Apr. 9, 1936, page 287. Abstract of paper presented to the American Society for Testing Materials. See *Metals & Alloys,* Vol. 6, Dec. 1935, page MA 511R/2. AIK (12)

Physical Properties of Metals as Affected by Conditions of Ammonia Synthesis. H. L. Maxwell. *Transactions American Society for Metals,* Vol. 24, Mar. 1936, pages 213-224. Paper and discussion from the Chicago Convention of the Society 1935. Deoxidized Cu and Cu alloys are more resistant to high temperature, high pressure H_2-N_2 mixtures than similar alloys containing oxide. 5 Plain C steel and low Cr-Ni alloys are severely embrittled up to 500° C. in contact with 3:1 H_2-N_2 mixtures at 1000 atm. Cr-W, Cr-Mo, and Cr-V steels show increased resistance to gas attack for times up to 1535 hrs. WLC (12)



DURALOY *asks:* **What is Your Corrosion or Heat-Resisting Problem?**

Duraloy-cast Tube Supports

DURALOY can bring to your problem an intimate knowledge of the wide application of Chrome-Iron, Chrome-Nickel and Nickel-Chrome alloys. It has an experience in casting these useful alloys dating back to 1922. It has production facilities second to none and better than most. It also has the technique, experience and facilities for producing sound centrifugal castings of these alloys.

Bring your corrosion and heat resisting problems to DURALOY—no matter what kind of a casting, forging or rolled product is involved.

. . . . . .

The Duraloy Company can supply the following in Chrome-Iron, Chrome-Nickel and Nickel-Chrome alloys: sand and centrifugal castings of all kinds; forged shapes; sheets, tubes; wire; nuts; bolts; etc.

THE DURALOY COMPANY

13. CORROSION AND WEAR

V. V. KENDALL, SECTION EDITOR

A Comparison of Certain Metals regarding their Resistance to Corrosion by a Natural Strong Brine Water. Harold B. Salt. *Chemistry & Industry,* Vol. 55, July 17, 1936, pages 205T-207T. A study of the corrosion resistance of a large number of metals and alloys to the corrosive action of natural brine water. Metals in the following groups were tested: (1) Cu alloys in which the Cu content ranged from 71-96% with varying percentages of Zn, Al, Sn, Ni and Fe; (2) Ni alloys in which the Ni content ranged from 20-68% with varying percentages of Cu, Cr, Zn, Fe and some having traces of Si and Mn; (3) stainless steels in which the Cr content ranged from 12-18%, the Ni content 8-12%, Fe from 74-76%. Several of the alloys in this group contained the stabilizing elements Mo, Ti, W and Co; (4) pure metals as Al, Cr, Cu, galvanized Fe, Ni, Sn, Zn, Pb, Fe (cast and rolled), and tool steel. 4 tables of data are given.
AAA (13)

Influence of Impurities on Oxidation of Copper at Elevated Temperatures. S. P. Gvozdov & N. N. Nagornov. *Metallurg,* Vol. 11, June 1936, pages 78-82. In Russian. Strips of pure Cu were suspended in a vertical tube furnace provided with a trap door at the bottom. After heating to proper temperature for the desired time the door was opened and specimen rapidly transferred into water. Amount of oxidation was determined by weighing both specimen and scale which separated from its surface. The results are in good accord with data of N. B. Pilling & R. E. Bedworth, *Journal Institute of Metals,* Vol. 29, 1923, page 529.
(13)

Korrosion IV. VDI Verlag, Berlin, 1935. Paper, 6¾ x 8¼ inches, 76 pages. Price 5 RM.

A collection of papers presented at the Symposium on Corrosion, Nov. 20, 1934, under the auspices of the Verein deutscher Eisenhüttenleute, Verein deutscher Chemiker, Deutsche Gesellschaft für Metallkunde and Verein deutscher Ingenieure. The papers have been abstracted individually in *Metals & Alloys* as indicated: Carl Carius, Die Korrosion der Metalle in Wasser und wässrigen Lösungen, pages 1-8 (*Metals & Alloys,* Nov. 1935, page MA 463L/4). Measuring Unit for Corrosion (Masseinheit für Korrosion. DIN E 4851) F. Tödt. *Aluminium,* Vol. 18, Apr. 1936, pages 133-134. The committee on corrosion has drawn up a plan for testing materials for corrosion, treatment of specimens and comparison of results. Analytical and constructive units are distinguished: the former is the loss in weight in g./m.²/day, the latter the decrease in thickness in mm./yr.
Ha (13)

The Modern Theory of Corrosion. W. W. Kittelberger. *American Paint Journal,* Vol. 20, June 29, 1936, pages 23-24, 26, 54, 56, 58. A brief discussion of the electrochemical theory of corrosion. Corrosion is classified as: (1) corrosion by direct chemical attack, (a) in the absence of water, (b) in the presence of water; (2) corrosion in which the dissolving metal displaces another metal from solution, (3) corrosion in which the dissolving metal displaces H from solution, (a) H is visibly evolved, (b) H is not visibly evolved because the discharge potential of H on the cathode surfaces is greater than the potential of the dissolving metal. Anodic control and the use of chemical inhibitors are discussed.
WHB (13)

The Rate of Solution of Copper in Dilute Aqueous Reagents. Cecil V. King & Lillian Weidenhammer. *Journal American Chemical Society,* Vol. 58, Apr. 1936, pages 602-607. The rate of solution of polycrystalline Cu from a rotating cylinder has been measured in solutions of acetic acid and various oxidizing agents. It is concluded that the rate of solution in the ferric salt solutions is largely diffusion-controlled. In the acetic acid solutions the rate may be entirely or partly controlled by the rate of the chemical reaction; in some of these solutions surface coatings may mechanically prevent access of reagent to the Cu surface or otherwise change the nature of the reaction.
MEH (13)

Action of Cream and Butterfat on Metals and the Influence of Metals on the Quality of Butter and Butterfat (Die Einwirkung von Rahm und Butterfett auf Metalle sowie die Qualitätsbeeinflussung von Butter und Butterschmalz durch Metalle) W. Mohr & A. Eichstädt. *Molkerei-Zeitung,* Hildesheim, Vol. 50, June 19, 1936, pages 1480-1482. Of numerous metals and alloys studied, V_2A-steel, Al, and Cr-plated or tinned Cu strips were corroded least when exposed in heated or soured cream. Metals corroded most included Ni, Fe, brass, plain Cu, and Al-Mg alloys. The metals corroded least had least effect upon the flavor of butter. Cr-plated Cu and tinned Cu were corroded less than other metals by cream, when exposed in combination with V_2A-steel, Al, and Cu. No flavor defects were produced in butterfat by the use of tinned or enameled containers, or by V_2A-steel containers.
GPS (13)

ALCUMITE

a corrosion-resisting copper-base aluminum alloy may be useful in your plant

ALCUMITE is satisfactorily resistant to a large number of corrosive chemicals and solutions.

For instance: Alcumite is recommended for sulphuric acid under non-oxidizing conditions: for concentrations as high as 80% up to 200°F. and as high as 60% up to 250°F.

Alcumite is resistant to a wide range of such corrosive solutions as

- **Organic acids**
- **Animal and vegetable oils**
- **Sludge acids**
- **Many sulphates, chlorides and other salts.**

Alcumite has high tensile strength; can be machined with the same equipment as used for mild steel and is adaptable to mechanical processing, including forging.

Alcumite is available in cast forms and as hot rolled bar.

Standard equipment made in Alcumite consists, in part, of

- **Centrifugal pumps**
  - **standard**
  - **self-priming**
- **Valves of many types**
- **Circulating Steam Jets**
- **Tank outlets**
- **Pipe fittings**
- **Exhaust fans**
- **Tie rods**
- **Bars, bolts, nuts**

Special equipment is made to the customer's specifications.

For more complete data, chemical resistance, physical properties and suggested applications, write for Bulletin 701—sent free upon request.

BERYLLIUM

Its Production and Application

By Zentralstelle fuer wissenschaftlich-technische Forschungsarbeiten des Siemens-Konzern

Translated by Richard Rimbach *and* A. J. Michel

NOT only is this the first thorough treatise on beryllium to appear in English, which fact alone makes it welcome to American metallurgical engineering, but it presents in concise and usable form what might be termed "all about" this coming metal. The authoritativeness of this book arises from the fact that it is essentially an account of ten years' work on beryllium and its alloys by the very men who systematically conducted these researches, augmented by reports contributed by other workers in this field. This book will be found indispensable not only to workers in the more obvious field of light-metal alloys, but equally to those interested in the alloys of the heavier metals.

CHAPTERS

Introduction.
Outline of the Research Program on the Production and Uses of Beryllium.
The Analytical Chemistry of Beryllium.
The Occurrence of Beryllium.
The Thermal Reduction of Beryllium.
Investigation on the Dressing of Raw Beryl and on the Production of Beryllium Salts Suitable for Electrolysis.
Electrolytic Production of Beryllium.
The Influence of Bath Composition and Bath Temperature on the Stock-Goldschmidt Siemens & Halske Method for the Production of Beryllium.
Physical and Chemical Properties of Beryllium.
The Production of Electrolytic Deposits of Beryllium by High Temperature Electrolysis.
Direct Electrolytic Production of Beryllium Alloys.
The Structure of Beryllium-Copper Alloys.
Physical Properties and Age Hardening of Beryllium Copper Alloys.
Changes in the Electrical Conductivity and the Volume During the Age Hardening Beryllium-Copper Alloys.
The Changes in the Modulus of Elasticity During the Age Hardening Beryllium-Copper Alloys.
Changes in the Microstructure of Beryllium-Copper Alloys Due to Age Hardening.
X-Ray Investigation of the Age Hardening Process in Beryllium-Copper Alloys.
Theory of the Age Hardening Process Based on the Investigation of Beryllium-Copper Alloys.
The Effect of Small Additions of Phosphorus on the Age Hardening of Beryllium-Copper Alloys.
Ternary Copper-Base Alloys Containing Beryllium.
Beryllium-Nickel Alloys.
Beryllium-Iron Alloys.
Magnetic Measurements of Iron-Beryllium Alloys.
Aluminum Beryllium Alloys with an Appendix on Silicon-Beryllium Alloys.

331 Pages - 198 Diagrams and Photomicrographs
Price $10.00

METALS & ALLOYS
REINHOLD PUBLISHING CORPORATION
BOOK DEPARTMENT
330 W. 42nd St. New York, N. Y.

Existence of an Oxide-film on Gold (Über die Existenz einer Oxydschicht auf Gold) W. J. Müller & E. Löw. *Berichte der deutschen Chemischen Gesellschaft*, Vol. 68, May 8, 1935, pages 989-991. The development of an oxide film on Au was investigated by treating the metal anodically in 5 *N* HCl and examining the surface with reflection-polarizing microscope. Passivation phenomena and photomicrographs demonstrate the existence of the film. FPP (13)

Boiler Protection against Corrosion (La Protection des Chaudières contre les Corrosions) Hans Richter. *Revue Universelle des Mines*, Vol. 12, Apr. 1936, pages 166-168. It is maintained that scale and slime are the worst foes of a boiler and often the cause of corrosion; for that reason removal of the slime is important and should be done regularly and, if possible, continually. Several methods to accomplish this by mechanical means are described. Ha (13)

New Laboratory Data Relative to Embrittlement in Steam Boilers. F. G. Straub & T. A. Bradbury. *Transactions American Society Mechanical Engineers*, Vol. 58, July 1936, pages 389-390. A new series of tests showed that purified $NaOH$ will not produce cracking of steel test specimens in short-time tests, whereas technical $NaOH$ made by the lime-soda process will produce cracking, and that cracking is due entirely to the impurities. When silica is present in sufficient amounts along with pure caustic, cracking will take place. The results seem to indicate that one or more catalysts must be present in the NoOH solution in order to cause cracking within a reasonable period of time. Ha (13)

Corrosion of Milk Tins in Ocean Transit. W. E. Seyer & R. J. Donald. *Canadian Chemistry & Metallurgy*, Vol. 20, July 1936, pages 227-228. Experimental data indicate that there are 2 underlying causes operating to bring about the rusting of the tins: i.e. the change in temperature of the humid air which produces sweating and the amount of salt contained in the sweat beads. To avoid the formation of rust it is necessary to prevent moisture from condensing on the tins, due to rapid temperature changes of humid air and to keep the salt content in the air as low as possible. The efficiency of certain carton containers sealed by various means is indicated. The more waterproof the container the more efficient the corrosion resistance. WHB (13)

Dissolved Oxygen and Embrittlement. W. C. Schroeder & O. C. Ralston. *Power*, Vol. 80, March 1936, page 145. Historical statement in regard to discovery of effect of SiO_2 in caustic embrittlement. AHE (13)

Electro-deposited Nickel. *Journal of Commerce, Shipbuilding & Engineeering Edition*, April 16, 1936, page 11. Applications of Ni deposition in marine engine maintenance for the repair of turbine shafts and turbine reduction gear shafts, where wheels have become loose due to wear; for the repair of turbine shafts and turbine blades, which have corroded and have been built up with deposited Ni or Cr; and for the repair of expansion sleeves, gudgeon pins, propellers, and piston rods. JWD (13)

Accelerated Tests Aid in Selection and Comparison of Metal Finishes. *Steel*, Vol. 98, Apr. 6, 1936, pages 42-43. Electrogalvanized apparatus was found to discolor rapidly in the field and it was decided to replace the Zn finish with an Al enamel. Test panels, made up of the Zn finish and 4 different systems of Al finish, were subjected to roof exposure, weatherometer, industrial atmosphere, aerated H_2O, and high-temperature high-humidity tests. Results showed that most of the Al finishes would give ample protection from corrosion and at the same time resist discoloration far longer than an electrogalvanized surface. It is also easy to touch up in the field. Although not rated the best finish of those tested, it was decided to use 1 coat baked Al over phosphate processed steel, as it was cheaper to apply than Zn and withstood the tests even better than the Zn. MS (13)

The Corrosion of Various Constructional Steels. J. Brillie, A. Leroy & A. Roux. *Iron & Coal Trades Review*, Vol. 132, June 19, 1936, pages 1109-1110. A report of researches on welding rods and electrodes for corrosion-resisting joints to the 12th International Congress of Acetylene, Oxy-acetylene Welding and Allied Industries described experiments from which it can be concluded that the metal deposited in a weld should be perfectly sound and free from air bubbles or inclusions of slag and oxides. The chemical resistance of the weld can be further improved by certain additions, such as Cr and Cu, Mn and Si, or Ni. Whereas additions of Cr and Cu are the most effective against acid attack, Ni produces the best chemical resistance against saline corrosion (sea water). Both parent material and weld metals should contain the least possible amounts of P and S impurities. Ha (13)

Failure of Metals due to Cavitation under Experimental Conditions. H. N. Boetcher. *Transactions American Society Mechanical Engineers*, Vol. 58, July 1936, pages 355-360. Recent experiments confirmed the mechanical character of cavitation in metals. Hardness tests showed that with many metals appreciable hardening of the surface is caused by cavitation and in Cu alloys and austenitic steels by strain lines. As only a small area is affected in this kind of failure, the name of "cavitation fatigue" is suggested. In order for a metal to have high resistance against cavitation fatigue it should have high corrosive resistance in the water in which it is used, and possess physical and metallurgical properties which result in high fatigue resistance, i.e. a high initial hardness with satisfactory toughness or susceptibility to considerable strain hardening The results are illustrated by many micrographs of cavitation failures. Air Speed and the Scaling of Iron. W. Baukloh & O. Reif. *Metal Treatment*, Vol. 2, Spring 1936, pages 32-33. Abridged translation from *Metallwirtschaft*. See "Effect of Air Velocity on the Scaling of Iron," *Metals & Alloys*, Vol. 7, July 1936, page MA 372R/3. JCC (13)

Sweating of Sheets in Transit and Storage. G. C. Bartells. *Journal American Zinc Institute*, Vol. 17, 1936, pages 98-105. Galvanized sheets must not be stored in horizontal piles as temperatures changes cause condensation of moisture between the sheets. Chemical action then causes a white carbonate deposit on the surface of the Zn, which very quickly destroys the protective coating. Many cases have been found where sheets, after faulty storing in the warehouse, have shown disastrous effect of rusting only a few weeks after being placed on roofs or similar places where they are exposed to the elements. BHS (13)

Progress of Corrosion as Demonstrated by Contact Photographs (Ueber den Verlauf der Korrosion an Hand von Kontaktphotographieen) N. Goldowski. *Korrosion & Metallschutz,* Vol. 12, May-June 1936, pages 108-118. 2 types of corrosion can be distinguished: (1) corrosion characterized by the increase of points of attack according to an exponential function, and (2) corrosion by which the points of attack increase in surface. The methods of investigation are described for light metals and Fe metals, and the preparation of the surface of the sample by etching with a 3% NaCl solution with 0.3% $MgCl_2$ explained; the small holes developed in the corrosion test are photographed on photographic paper in contact with the sample. A theory is developed to calculate the progress of corrosion. 5 references. Ha (13)

New Materials Prolong Life of Equipment. James A. Lee. *Chemical & Metallurgical Engineering,* Vol. 43, July 1936, pages 359-363. Based on a paper given before the Chemical Engineering Congress of the World Power Conference, London, England, June 23, 1936. Developments in stainless steels, Cu-Ni alloys, Cu alloys, Pb, Al, and precious-clad metals are mentioned. 12 references. PRK (13)

The Atmospheric Corrosion and Tarnishing of Tin. L. Kenworthy. *Metal Industry,* London, Vol. 47, Dec. 6, 1935, pages 555-560; Dec. 13, 1935, pages 583-584. Report of an investigation conducted for the British Non-ferrous Metals Research Association, supported by the Tin Research & Industrial Application Committee. Soil-Corrosion Studies, 1934. Rates of Loss of Weight and Pitting of Ferrous Specimens. K. H. Logan. *Bureau of Standards Journal of Research,* Vol. 16, May 1936, pages 431-466. The soil-corrosion investigation which was started in 1922 was originally planned to cover 12 years, plus the time required to write the final report. In 1934 the last of the original specimens were removed from 23 soils, but additions to the original test have so altered the plans that there now remain in the ground 7,500 specimens buried by the National Bureau of Standards and approximately 2,000 specimens of protective coatings prepared by research associates. In general, the results of the examination of the specimens removed in 1934 confirm earlier conclusions. The additional data permit the calculation of the standard errors for certain classes of data. The average maximum penetrations for the wrought-Fe, Bessemer, and open-hearth specimens do not differ by more than a few per cent. The specimens of open-hearth Fe and of open-hearth steel containing 0.2% of Cu appear to pit slightly more deeply than the other wrought specimens. In some soils cast Fe corrodes somewhat more rapidly than steel. Soils differ so greatly in corrosiveness that the average rates of corrosion or the average life of a pipe have little practical value. The addition of Cr to steel reduces the loss of weight by corrosion and the number of pits, but even a large percentage of Cr will not prevent serious pitting. This is especially true with respect to soils containing chlorides. The addition of Ni, with or without Cr, tends to reduce the depth of the pits. Certain materials seem to be especially suited or unsuited to certain types of soils. WAT (13)

14. APPLICATION OF METALS AND ALLOYS

Improved All-Electric Typewriter Is Designed for Quietness and Speed. *Steel,* Vol. 98, May 4, 1936, pages 62, 65. Most of the approximately 600 parts of the machine are of steel, accounting for 57% of total weight. Al alloy die castings, Mg alloy, cast Fe, and brass tubing also are used. MS (14)

Bulk Sugar Kept Uncontaminated in Stainless Steel Freight Car. *Steel,* Vol. 98, Apr. 27, 1936, page 56. Bottom of car is composed of 4 hoppers fabricated of stainless steel, interior surface of which is polished to mirror-like smoothness. Lining of vertical sides and roof is of a Zn alloy. MS (14)

Structural Steel Frame, Zinc Exterior Panels Used in New Home Design. *Steel,* Vol. 98, Apr. 13, 1936, page 17. Describes method of Walter W. Ahlschlager, adopted by Estate Homes Inc., Chicago. Continuous length plates of pure Zn, without horizontal joints and with concealed vertical joints, are used for exterior walls. These plates are attached by a patented method to the framing. All framing members are structural steel similar to skyscraper construction and are shop fabricated from standard shapes. MS (14)

Prefabricated Building Units of Steel for Residence Construction. E. C. Kreutzberg. *Steel,* Vol. 98, Apr. 6, 1936, pages 36-38. Describes system of construction developed by the Reynolds Corp., New York, which permits complete freedom in executing building plans. Floor joists, studs, and other framing members are made of galvanized steel sheets rolled to the desired form and filled with nailing concrete. Plaster base fabric or lath is built up of V-shaped steel ribs, spaced 4" apart horizontally, and electrically welded to vertical cross wires which are woven through waterproof paper. Al foil is used for insulation. Floor slabs are formed by casting nailing concrete on a fabric backing heavily reinforced by steel. Cu is used for roofing. MS (14)

The Modern Tin Box. H. K. S. Lindsay. *Tin,* May 1936, pages 1-4. New applications of tin plate containers in Great Britain are discussed. These include cans for beer, oil, and cheese previously introduced in the U.S.A., new types of tooth powder dispensers and containers for vacuum packing of manufactured products such as medicated tablets, typewriter ribbons and tobacco as well as foods. BWG (14)

Use of Metals in Modern Engineering: Ferrous Metals. Light Metals. Lead (L'Emploi des Métaux dans la Construction Moderne. Les Métaux Ferreux. Les Métaux Légers. Le plomb) Michel Nation. *La Technique Moderne,* Vol. 28, Apr. 15, 1936, pages 266-270. Reviews applications of pure Fe, stainless steels, pure Al, duralumin, studal, almasilium. A special section is devoted to applications of light alloys in architecture. Uses of Pb in radiography are briefly described. FR (14)

Influence of Metals on Milk (Der Einfluss von Metallen auf die Milch) W. Ritter. *Schweizerische Milchzeitung,* Vol. 62, July 24, 1936, pages 331-332; July 28, 1936, pages 337-338. The presence of traces of Cu or its alloys was found to be detrimental to the flavor of milk, and caused the development of tallowiness and other catalytic oxidation flavors. Fe, Ni and Zn were less harmful. Al and its alloys, and different types of stainless steel were without effect. The latter metals are most desirable for storing, conveying and pasteurizing milk and milk products. GPS (14)

Tantalum Carbide—Its Relation to Other Hard Refractory Compounds. Philip M. McKenna. *Industrial & Engineering Chemistry,* Vol. 28, July 1936, pages 767-772. This article includes a compilation of physical properties of the compounds of the metals, Ti, V, Cr, Zr, Cb, Mo, Hf, Ta, and W. The melting points of carbides of Cr, Mo, and W are lower than those of either C or the metal; carbides of Ta, Cb, V, Hf, Zr, and Ti have higher m.p. than the respective metals. Uses of hard carbides of W and Ta as constituents of tool materials are discussed. TaC compositions are used to tip lathe and boring tools, and can cut stainless steels, stellite, Duralloy, Silcrome, Illium, and Hadfield's 12% Mn-steel. TaC and TaB_2 may be boiled with HNO_3 or with HCl or mixtures of the two without effect. A mixture of HF and HNO_3 alone will attack them. The 80% TaC compositions have a strength of 275,000 lbs./in.$_2$ on cross rupture tests. MEH (14)

The Problem of High Grade Materials and Machine Tool Design in Germany. Walter Storck. *Machinery,* London, Vol. 48, Apr. 9, 1936, pages 37-40. Reduction in consumption of Ni, Cr, Cu, Sn as raw materials imported into Germany is present economic aim. No substitutes have so far been found for machine tool members which take heavy or impact loads. The program calls for the use of alloys for surfaces that take the wear, corrosion or members that take the impact, and back this minimum section with cheaper plain cast steel or plain C steel. Mo cast Fe is sometimes used for bed castings but machinability is poor as compared with Ni cast Fe. Spindles of mild steel are built up with shrink on bushings of Ni steel. The trend is toward roller or taper bearings which allow use of mild steel spindles and shafts, the rollers of the bearings representing a minimum use of the alloys. Gears are built up by use of case hardened rim. Economics of the situation are such that production costs are often increased by the necessity of reducing alloy use. Substitutes for high grade bronzes are sought among Zn-Cu-Al and Cu-Pb alloys. The 85 Zn, 10 Cu, 5 Al, U. S. A. bearing metal has found approval in Germany as a substitute for the bronzes. Cast Fe was substituted for bronze in a clutch fork and synthetic molded material riveted on with Cu to prevent seizure. The molded materials are substituted for bronze where there is no swelling in the presence of oil. WB (14)

Effect of Modern Materials on Fine-Mechanical Constructions (Beeinflussung der Konstruktionen in der Feinwerktechnik durch neuzeitliche Werkstofffragen) W. Skawran. *Feinmechanik & Präzision,* Vol. 44, May 1936, pages 69-74. The influence which improved mechanical properties of metals and newly developed alloys have had on technical capacity, accuracy, economy and competitiveness of fine instruments are reviewed and illustrated by many examples. The Setting of Amalgams. MARIE L. V. GAYLER. *Dental Cosmos*, Vol. 77, Nov. 1935, page 1140. Abstract from *British Dental Journal*, London, Vol. 59, Sept. 1, 1935, pages 245-251. The composition of the amalgam was found to vary with that of the alloy; a range of 25-27% Sn was selected for the alloy. Amalgams made from these alloys contained 13-16% Sn and 40-47% Hg. The amount of Hg used in mixing had little effect on the amalgam composition, if the excess was expressed immediately after mixing, and small variations in Hg content could not be associated with variations in dimensional changes of the amalgams. The amount of Sn removed by expressing the Hg was less than 2% of the original amount in these alloys but was greater with higher Sn contents. OEH (14a)

Aluminum Bells. HARRY N. HOLMES. *Nature*, Vol. 137, May 2, 1936, page 745. Brief note on use of Al for casting bells. CSB (14a)

Sleeve Bearings in High-speed Combustion Engines (Beiträge zur Gleitlagerfrage in schnelllaufenden Verbrennungsmaschinen) H. MANN. *Automobiltechnische Zeitschrift*, Vol. 39, June 10, 1936, pages 290-292. Bearing materials and their working are discussed. Two principal groups are distinguished: (1) Soft materials with Brinell hardnesses below 45 kg./mm.^{2}; to this group belong bearing metals on a basis of Sn, Pb, Cd and Pb-Cu alloys with or without small additions of hardening elements. (2) Hard bearing materials with Brinell hardnesses above 45 kg./mm.^{2} which include the various bronzes, light metals and gray Fe with hardnesses up to 200. Their particular properties under different conditions and machining methods are described. Ha (14a)

Telephone Lines of Aldrey Wire (Fernweldeleitungen aus Aldrey-Draht) M. PREISWERK & W. MÜLLER. *Aluminium*, Vol. 18, May 1936, pages 184-191. Telephone lines of Cu, bronze and galvanized Fe have (in Germany) been replaced by lines of Aldrey which, with a specific weight of 2.7 has mechanical advantages and does not require imported raw materials. Physical properties are compared with other materials and methods described for joining mechanically since soldering is not recommended. Ha (14a)

Aluminum Industry Makes Rapid Strides During Fifty Years Since Hall's Discovery. *Amercian Paint Journal*, Vol. 20, July 13, 1936, pages 16, 18, 21. An historical sketch dealing principally with the development of Al bronze powder and the advantages of Al paints. WHB (14a)

M. GENSAMER, SECTION EDITOR

Cast Iron for the Manufacture of Glass Bottle Moulds. N. L. EVANS, W. GOACHER & J. E. HURST. *Journal Society of Glass Technology*, Vol. 20, Feb. 1936, pages 45-53; discussion, Apr. 1936, pages 63-71; abstract, *Foundry Trade Journal*, Vol. 54, Feb. 27, 1936, page 171. Alloy Fe for bottle molds could probably be produced that would be better than plain Fe, but for cost reasons plain irons are used. The glass temperatures within the mold vary from 700° to 1000° C., the outside temperature of the mold from 300° to 500° C. Recommended composition of Fe is total C not over 3.10%; Mn 0.80-1.50%; S 0.07% Max., P 0.45% Max.; with Si ranging from 2.50% for a casting ½" thick down to 1.30% for one 2½" thick. Brinell hardness is 215-235. High Mn is used to obtain a fine-grained structure, S is kept low by soda-ash treatment, P is held to 0.45% because of alleged deleterious effect (not explained) on high temperature properties. Failure of molds is related to propensity toward growth of the Fe. The Fe should be close so as to take a good polish, hence the total C should be kept down. In discussion it was pointed out that the interior surface should be made dense by chilling and that by varying the chill according to the wall thickness of the mold, metal of one Si content could be used for a variety of thicknesses. Cast Fe was approved for molds meant for short runs, but austenitic heat resistant alloys were preferred by several for long runs. FeNi + Cr + W, and alloys with 20 Cr, 25 Ni or 11 Cr, 58 Ni were mentioned. Authors' reply maintains that it is better to adjust Si than to chill. HWG + AIK (14b)

Cast Camshafts and Crankshafts (Gegossene Nocken- und Kurbelwellen) H. CORNELIUS & F. BOLLENRATH. *Giesserei*, Vol. 23, May 8, 1936, pages 229-236. Present trend in using cast instead of forged shafts, reasons for using them and advantages, experiences in automobile manufacture and in pumps, are discussed at length. 39 references. Ha (14b)

Wood Joins Steel in New Sheet Applications. ROGERS A. FISKE. *Iron Age*, Vol. 138, July 2, 1936, pages 30-33. Describes products of Haskelite Mfg. Co., Chicago, known as "Steelwood" and "Plymetl." The former has facings of thin wood veneer glued to sheet steel; the latter has facings of thin sheet steel glued to plywood. Applications extend all the way from novelties to architectural treatment. Steelwood is adapted to forming operations which do not involve much stretching along grain of the face veneer. Plymetl is much stronger and stiffer than its component parts. Galvannealed sheet steel of special grade is material most commonly used. VSP (14b)

The Development of Proferall Cast Camshafts. D. J. VAIL. *S. A. E. Journal,* Vol. 39, July 1936, pages 288-292. Details of process, properties of processed-ferrous-alloyed-iron (Proferall) camshaft for aero engines. Analysis, total C 3.10-3.40, Si 2.10-2.40, S .10 max., P .20 max., Mn .50-.75, Cr .75-1.00, Ni .20-.40, Mo .40-.60. Scrap Fe and pig is melted in cupola, Cr briquettes added and melt transferred to electric furnace for final alloy additions and refining. Brinell as cast 262-293. Results of wear tests on 5 camshaft gears are shown in a table along with chemical analysis and hardness, which together determine wear resistance rather than hardness alone. Both journal and bearing wear is less than for steel shafts. Thermal expansion is less for cast material. Production cost is lower. Discussion of machining follows. Details of finishing the cast shaft are given as practiced for the Hudson Motor Car. Advantages of modern forging methods are also reviewed in discussion. WB (14b)

Rock Drill Steel. C. H. VIVIAN. *Compressed Air Magazine,* Vol. 41, Apr. 1936, pages 4991-4997. The importance and extent of application of steel drills are discussed and methods of production and inspection described. P and S are the most undesirable impurities. Swedish production is in acid open hearth in small lots. Before rolling, billets are pickled, chipped, ground and pierced with an austenitic steel core, which is later extracted by breaking the ends of the external section, and stretching the core, after which it is cut and withdrawn by hand. The hole must be round, well centered and of uniform diameter throughout its length. Most rock-drill steel failures are fatigue failures, originating in surface defects. Inner surface of modern metal-core processed drill is far superior to that produced by the old sand-core or the mandrel-rolling methods. FPP (14b)

Corrosion Resisting Steels for High Strength. ERNEST E. THUM. *Metal Progress,* Vol. 29, June 1936, pages 49-55, 104; (abstract) *Steel,* Vol. 98, Mar. 9, 1936, pages 45, 75. Heat treatment of stainless steels results in very high properties indicating wide variety of engineering applications. 12% Cr with less than 0.09% C is capable of very high strengths; 1200° F. draw after 1750° F. quench results in over 100,000 lbs./in.^{2} tensile strength and 80 ft. lb. Izod. These excellent properties are taken advantage of in the application to turbine blading. Graphs are given showing the heat treated properties of various steels of the 0.30-0.40% C cutlery grade. Applications are discussed. WLC + MS (14b)

Steel Progress and the Steam Engineer. L. SANDERSON. *Steam Engineer,* Vol. 5, Mar. 1936, pages 242-243. The metallurgical developments of 1935 in heat-resisting steel, hard-facing processes, pure metal spraying, Re-coating, corrosion-resisting steels, steel for pressure vessels and alloy steel rivets are reviewed. AHE (14b)

Foresees Wide Application for New Low-Alloy High-Tensile Steels. *Steel,* Vol. 98, May 11, 1936, pages 76-78. These steels will find increasing use in the automotive field; structures such as elevated H_2O tanks, stand-pipes, transmission towers, elevators, stairways, and floors; overhead traveling cranes; clam-shell and other types of buckets; mine-cars and cages; gas-producers; conveyors and driving-chains; and the power-plant field. MS (14b)

Valve with Stainless Steel Disks is Designed for Hot Gas Service. *Steel,* Vol. 98, Apr. 6, 1936, page 58. Valve for blast-furnace and coke-oven gases has valve-seats and valve itself inclosed completely in a single steel casting. Unit is built with 2 stainless steel disks which are expanded against the seats by high pressure, mechanically applied. MS (14b)

Manufacture of Cast Iron Automobile Parts (La Fabrication des Pieces d'Automobiles coulées en fonte) BROCHETON. *Revue de Fonderie Moderne,* Vol. 30, Apr. 10, 1936, pages 109-115. Different kinds of molding, preparation of molding sands, composition of cast Fe used for different engine parts and correct casting temperatures are discussed. Ha (14b)

Wire Rope for Mining. G. H. CUTTER. *Mining & Metallurgy,* Vol. 17, June 1936, pages 283-285. Describes the manufacture, use and maintenance of wire rope in mining. Highly important requirements are best met by acid open-hearth steel, according to most manufacturers. Ropes are made in several grades such as: Fe, cast steel, extra strong cast steel, plow steel and improved plow steel. Ropes with fewest number of wires are best suited for resisting abrasion and corrosion. Gives various uses of the different grades of wire. VSP (14b)

Steel Tubing. *Times [London] Trade & Engineering,* Vol. 38, Dec. 1935, page XI. Outlines methods of manufacture and some uses. MS (14b)

Stainless Steels and Irons. *Times [London] Trade & Engineering,* Vol. 38, Apr. 1936, page XI. Deals with their development and applications. MS (14b)

Modern Boiler Manufacture. *Electrical Review,* Vol. 118, June 5, 1936, pages 807-809. Describes Renfrew, Scotland, works of Babcock & Wilcox, Ltd. Outlines equipment and operations, such as forging, welding, annealing, X-ray examination and founding. MS (14b)

Designation: A 82-34; *American Association State Highway Officials Standard,* A. A. S. H. O. No.: M-32; *American Standards Association,* A. S. A. No.: A 50.3-1936, 3 pages. AHE (14b)

Application of Alloy Steels. H. W. MCQUAID. *Iron Age,* Vol. 136, Dec. 26, 1935, pages 18-22. From a paper read before the American Institute, Dec. 13, 1935. See *Metals & Alloys,* Vol. 7, July 1936, page MA 378L/4. VSP (14b)

Use of Alloy Cast Iron Grows. GARNET P. PHILLIPS. *Automotive Industries,* Vol. 74, May 23, 1936, pages 732-740. Alloys most commonly used in the automotive industry are Ni, Cr, Mo, Cu, and Ti. The alloy cast irons are better adapted to heat treatment than unalloyed irons, and producers are constantly experimenting to find more serviceable metals. A number of metal compositions are given for various castings, as cylinder blocks, crank cases, valve seat inserts, valve guides, cylinder liners and sleeves, clutch pressure plates, exhaust manifolds, brake drums, iron dies, camshafts and crankshafts. BWG (14b)

Spirals and Other Fabricated Steel Units Permit Delivery of Clean Coal. L. O. RICHARDS. *Steel,* Vol. 98, Apr. 13, 1936, pages 42, 44. Spirals of riveted steel plate construction lower coal into distributor's bin at a uniform speed to prevent breakage. They are usually constructed of standard C plate but Cu bearing steel is sometimes used. Another product is a bin gate which gives coal a final screening as it is loaded into trucks. Gates and screens are of welded steel plate construction. Third unit is a self-supporting boom to facilitate truck loading. It is built up of standard steel shapes and plates welded together, except the drag trough which is bolted for replacement. MS (14b)

New Spring Formulas and New Materials for Precision Spring Scales. M. F. SAYRE & A. V. DE FOREST. *Transactions American Society Mechanical Engineers,* Vol. 58, July 1936, pages 379-387. Developments in springs for precision measuring instruments is reviewed and a new type of helical spring of a modified elinvar metal, containing 36% Ni, 8 or more % Cr, 4% of other elements such as Mn, Si, Mo, Cu and V, remainder Fe is described. Errors in the instrument could hereby be kept down to within 0.05%. High-degree cold-drawing combined with a special heat-treating process increased working stresses to 60,000 lbs./in.^{2} in shear while the error due to creep under working loads was less than 0.02%. Performance of the instrument is described in detail, the theory is given in an appendix. Ha (14b)

Materials for Exhaust Valves (Werkstoffe für Auslassventile) E. SCHMIDT & H. MANN. *Automobiltechnische Zeitschrift,* Vol. 39, June 25, 1936, pages 303-312. The extreme stresses which exhaust valves must withstand, especially in airplane motors, are explained and the properties of materials to satisfy these claims are discussed. Steels available at present for this purpose are: (1) steels which have very little high temperature strength, a transformation point within the service temperature and low resistance against scaling and corroding; these must not be used. (2) Steels which have no transformation point within the operating temperature and a good corrosion and scaling resistance, but the high temperature strength of which deteriorates quickly above 700° C., such as the martensitic Cr-Si steels; they can well be used if the temperature does not exceed 650°-700° C. (3) Steels like the austenitic Cr-Ni-W steels, which have no transformation point and high strength at elevated temperatures; they can be used for temperatures up to 800° C. and more if cooled. Their comparatively low hardness should be improved by nitriding or pressing of the surface. Tables showing composition of materials and properties are given. 30 references. Ha (14b)

Metal Lining Improves Concrete Tanks. HUGH S. WEIGHTMAN. *Chemical & Metallurgical Engineering,* Vol. 43, July 1936, pages 373-374. Methods of building large concrete tanks and lining them are given. PRK (14b)

Standard Specifications for Structural Steel. A. F. WEBBER. *Iron & Steel Industry,* Vol. 9, Mar. 1936, pages 210-213. Changes in a revision of British Standard Specification, No. 15, for Structural Steel for Bridges, etc., and General Building Construction are pointed out and discussed. CMS (14b)

Cylinder Castings for 4-6-0 type Locomotives, L. M. S. R. *Railway Gazette,* Vol. 64, June 5, 1936, page 1081. Illustrated description is given of cylinder castings and piping for a 2-cylinder general utility engine. Each cylinder is cast separately with its steamchest above it, the piping with smokebox saddle and base for the blast pipe forming another integral casting, bolted by means of flanged connections to the cylinder branches. Recent modifications have stiffened exhaust passages between frames. FPP (14b)

Constructions with 18:8 Steels (Constructions en acier inoxydable 18-8) ENÉA BOSSI. *Métaux,* Vol. 10, Dec. 1935, pages 315-323. General discussion of uses of stainless steels in railroad, aviation, and marine fields. GTM (14b)

Tools for the Engineer. BERTRAM BALFOUR. *Times [London] Trade & Engineering,* Vol. 38, Apr. 1936, page XV. Summarizes progress in design, quality and material for cutting-tools. MS (14b)

Stainless Steel as a Medium for Artists. OSCAR B. BACH. *Metal Progress,* Vol. 29, June 1936, pages 37-39. General. WLC (14b)

The Hubbing of Dies for Embossing Jewelry Parts. G. R. HOUGHTALING. *Metal Progress,* Vol. 30, July 1936, pages 46-48. Technique of this difficult work is described. Hub material used is C 0.65-0.75, Mn 0.50-0.60, Ni 1.50-1.75, Cr 1.50-2.00, Mo 0.25, V 0.25. Die material is C 0.60-0.70, Mn 0.60-0.70, Ni 1.25-1.75, Cr 0.65-0.85. WLC (14b)

European Status of the Stainless Steels. J. H. G. MONYPENNY. *Metal Progress,* Vol. 29, June 1936, pages 68-69. Martensitic stainless steels show no change except for the introduction of new 16-20% Cr, 1-3% Ni type which is more resistant to sea water and susceptible to treatment for high strengths. Ferritic types are low in impact and high temperature strengths. 16-18% Cr type has fair impact. This class of stainless is used mainly for its resistance to S gases. In the austenitic type, 18-8, Ti is used for freedom from weld decay. Si up to 6% is also effective in this respect and increases the resistance to oxidation and to many acids. It is used in aircraft and chemical applications. Chemical industries use much of the 4% Mo 18-8 which requires no treatment after welding and has increased acid resistance. This class as a whole is applicable to high temperature service. WLC (14b)

RICHARD RIMBACH, SECTION EDITOR

Use of Artificial Grinding Agents in the Tool Industry (Die Verwendung künstlicher Schleifkörper in der Werkzeugindustrie) Fritz & Kremer. *Oberflächentechnik,* Vol. 13, July 21, 1936, pages 159-164. Injury to health by dusts in grinding and polishing processes is discussed and statistics for compensation paid in German industries are given. Contrary to general views, wet grinding gives rise to the most serious injuries to the lungs. According to present experiences, grinding discs with mineral binders can compete very satisfactorily with natural sandstones. Oxidic Mg compounds as grinding material are conducive to reducing dust in grinding shops and lessen the danger of silicosis. Ha (15)

Standardization (La Normalisation) Girardeau. *Bulletin de la Société des Ingénieurs Soudeurs,* Vol. 7, Jan.-Feb. 1936, pages 2035-2053. Lecture before the French Welders' Society. Aim of standardization is threefold: (1) simplification to reduce as far as possible number of parts having the same use, (2) unification to allow parts to be interchangeable, (3) specification to establish minimum figures for quality testing of parts. Standardization is not only applied to materials but also to classifications, use of marks, definitions, etc. Author reviews French organizations and summarizes what has been done in France and in the world as to standardization. FR (15)

Filtration of Air in Foundries (Die Filterung der Luft in Giessereien) O. T. Koritnig. *Giesserei,* Vol. 23, June 5, 1936, pages 295-298. The hygienic and economic harmfulness of the dust in foundries is pointed out and means for dust removal by filtering or electrical precipitation and their respective advantages discussed. Ha (15)

Ford Production Methods. Hartley W. Barclay. Harper & Brothers, New York, 1936. Cloth, 9 x 12 inches, 215 pages. Price $5.00.

The entire text of this volume appeared as the January 1936 issue of *Mill and Factory,* of which Mr. Barclay is editor. The portions of metallurgical interest have been abstracted in *Metals & Alloys,* Vol. 7, June 1936. The book is unique in several respects, but chiefly because it manages to avoid the taint of propaganda that often accompanies descriptions of operating methods and experience. This is possibly because Mr. Barclay has done his job with the utmost thoroughness, omitting abstract generalizations, and describing processes in every necessary detail. The volume includes several flow sheets and floor plans and hundreds of photographs and drawings of parts and equipment. In addition to the sections of direct metallurgical interest, previously abstracted, the book contains chapters on Methods, Safety, Air-Conditioning, Buildings, Materials Handling, Mechanical Power, Transmission, Power, Tools and Accessories, and Lighting and Electrical Apparatus, and is well indexed. The volume should have distinct reference value to the production metallurgist and to all operating executives.
Fred P. Peters (15)—B—

Selected Chemical Analytical Methods for Iron and Steel Industries (Ausgewählte chemische Untersuchungsmethoden für die Stahl- und Eisenindustrie) Otto Niezoldi. Julius Springer Verlag, Berlin, 1936. Paper, 5½ x 8¼ inches, 152 pages. Price 5.70 RM.

This book is divided into 3 parts. The first covers analytical methods for the elements usually determined in Fe and steel, and some less commonly determined including Mo, Cu, W, V, Co, As, Al, and N. Methods are also included for the common ferro alloys. The second part is devoted to common nonferrous metals and alloys, and the third to slags, ores, boiler scale, dolomite, magnesite, lime, coal, water, producer and water gas.

The book outlines routine and not umpire procedures. Usually a few notes are included with each outline. Directions are brief and to the point. The degree of accuracy of the various methods is not discussed. It is not a text book, but because of the large number of procedures of varying nature outlined some steel plant chemists may find it to be a valuable addition to their library.
J. D. Sullivan (15)—B—

The Norwegian Aluminum Industry (Die Aluminium Industrie Norwegens) A. Brinck. *Aluminium,* Vol. 18, June 1936, pages 231-233. Development and present conditions are described. Annual production of 37,000 tons is possible.

Barite in France (La Baryte en France) V. Charrin. *La Revue Industrielle,* Vol. 66, Mar. 1936, pages 110-112. Explains chief sources of Ba ores in France (yearly production, 50,000 tons). Geological structure of countries where barite is extracted is explained. FR (15a)

Market Studies Uncover New Steel Uses and More Steel Profits. John Allen Murphy. *Iron Age,* Vol. 137, May 28, 1936, pages 27-33. Discusses method of procedure in market research and results obtained. VSP (15a)

The European and World Zinc Situation in 1935. O. W. Roskill. *Journal American Zinc Institute,* Vol. 17, 1936, pages 111-119. A review of the important European Zn producers, with production data, operating figures, ore supply, and important developments at various plants. BHS (15a)

Progress in English Cast Iron Production (Fortschritte in der englischen Gusseisenerzeugung) J. G. Pearce. *Giesserei,* Vol. 23, May 22, 1936, pages 262-265. Development, methods of practical and theoretical research, organization and testing methods are reviewed, and the activity of the British Cast Iron Research Association is described. 14 references. Ha (15a)

The Nickel Industry in 1935. Robert C. Stanley. *Metal Industry,* London, Vol. 48, Jan. 10, 1936, pages 32-35. An economic survey of the industry showed that in 1935 more Ni was consumed than in any previous year. While a portion was for munitions most of it went into diversified peacetime industrial work. This, in part, was attributed to the greatly increased investigative research and development work which has been carried on for a number of years by the producers. Numerous examples are cited in both ferrous and nonferrous fields where the addition of Ni or the development of new alloys have made possible new applications of materials. HBG (15a)

Zinc as a Chemical Raw Material. B. R. Silver. *Chemical Industries,* Vol. 38, Jan. 1936, pages 25-28; Feb. 1936, pages 141-144. Discussion of world production, specifications, sales and consumption, and uses. Summary of price fluctuations over several years. Functions of American Zinc Institute discussed. RAW (15a)

Great Lakes Levels Mean Dollars to Steel Industry. F. W. Trezise. *Steel,* Vol. 98, Apr. 27, 1936, page 36. Discusses economic value of maintenance of sufficiently high water levels, particularly in lakes Michigan and Huron, to make use of the maximum available draft of vessels. It has been calculated that a loss of 1 ft. of draft in an average year means a loss of $8,000,000 to lake shippers. MS (15a)

Metal Ore Deposits in Vosges (Les Gîtes Métallifères des Vosges). C. Thirion. *La Revue Industrielle,* Vol. 66, Apr. 1936, pages 141-151. General. FR (15a)

Working Methods of a Modern Research Laboratory in Developing Aluminum Alloys (Die Arbeitsweise eines modernen Forschungslaboratoriums bein der Entwicklung von Aluminiumlegierungen) A. v. Zeerleder. *Aluminium,* Vol. 18, July 1936, pages 297-298. Procedure in testing properties of new materials and releasing for commercial exploitation after they have been found satisfactory are described. Ha (15a)

■ 15a. Economic ■

Coal, Iron and Steel in Germany. *Iron & Coal Trades Review,* Vol. 133, July 24, 1936, pages 136-137. Statistics on production, exports and imports of ores, coke, scrap, and Fe and steel; development of syndicates and financial organizations are discussed. Ha (15a)

1935 Steel Ingot and Casting Output in Excellent Gain over Previous Year. *Steel,* Vol. 98, May 11, 1936, pages 40-41. Official figures of the American Iron and Steel Institute on production of steel ingots, castings, and rolled products. MS (15a)

The Copper Industry in 1935. Output and Production Costs. G. Abrahamson. *Metal Industry,* London, Vol. 48, Jan. 31, 1936, pages 155-156. In Mar. 1935 delegates of the great Cu-producing companies met in New York to agree upon a restriction of output. In spite of the fact that world consumption of Cu was continuing to increase, factors that counterbalanced the favorable effects of this increase were (1) American producers considered the European market a permanent outlet for their surplus stock, (2) new sources of production, with a low cost output, were now a factor demanding consideration, and (3) by-product Cu also became a serious factor. While all parties of the New York agreement adhered to the restrictions there was a slight increase in production in 1935 over 1934. Germany was about the only major country, outside of the U. S. A., in which Cu-consumption did not increase during the past year. This is attributed to the greatly increased quantities of Cu and brass scrap purchased by Germany. Costs of production of the various producers are discussed and it is shown that in the mines of South Africa, Cu can be produced at the lowest cost. However portions of the costs of production of some of the other companies are offset by revenue received from the sale of other metals. It is believed that possibilities of replacement of Cu by Al and other metals has been overestimated. HBG (15a)

A Survey of Engineering and Metallurgical Progress. G. E. Wolstenholme. *Proceedings Institution of Mechanical Engineers,* Vol. 131, Nov.-Dec. 1935, pages 525-629. Change and development of engineering methods in the last 40 years are reviewed. Ha (15b)

Early Chinese Metallurgy. E. A. Smith. *Metal Industry,* London, Vol. 48, Jan. 10, 1936, pages 27-31. An exhibition by the Royal Academy in London of work of Chinese craftsmen has raised the question of the production and working of metals in ancient China. A period of 35 centuries is covered by exhibits which begin with samples of the Bronze Age and continue as far as 1800 A.D. Until recent years little effort has been made to trace the history of metal working in China due to the opposition of both the government and the people in the country. This article is a brief summary of recent investigations made by A. S. Wheler and Robt. Slessor. It is their belief that in the outlying districts today the natives follow empirically methods of earlier days which have not been changed since 2850 B.C. All the base metals, as well as Au and Ag were produced in China before our civilization began by methods showing a sound knowledge of the principles of metallurgy. Although crude equipment was used and at a low efficiency, yet metals of high purity were obtained. Backed by recent discoveries of archaeologists, it is suggested that the art of metallurgy may have begun in Asia and possibly in China. The mineral resources are inexhaustible and practically untouched. The crude methods used in obtaining Sb, Cu and the early bronze, the "lost wax" process—believed to have been originated by the early Chinese, Au and Fe are outlined. The smelting of galena appeared to be solely to obtain the Ag present. The equipment and process used are briefly discussed. In a similar manner the methods used for obtaining Hg, Sn, Zn, and the smelting of complex ores are considered. The article is illustrated with drawings of the crude equipment used. 3 references. ENGINEERING-SALES REPRESENTATIVES SEEK ADDITIONAL PRODUCTS OR PROCESSES

A well established firm, directed by seasoned chemical, metallurgical, and mechanical engineers, with unusual abilities and contacts in the application and sale of Process Equipment, seeks contact with manufacturers desiring to extend their sales along these lines.

Particularly successful in adapting standard or special process equipment to customer's needs, thus broadening and strengthening markets. Specialized knowledge and experience in problems involving corrosion.

References of the highest character furnished and required. Address Box No. A-2, METALS & ALLOYS, 330 W. 42nd St., New York, N. Y.

FREE SERVICE DEPARTMENT

Junior Executive Available—M. I. T. Graduate. General engineering experience, Chase Brass and Copper Company. Purchasing chemicals and equipment, R. H. Macy and Company. Single, christian, references. Box No. MA-4, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

POSITION WANTED: INSPECTOR, SUPERVISOR or INSTRUCTOR of WELDING. Specialized 8 years in arc welding. Knowledge of Metallography, Heat-Treating and Physical Metallurgy. Capable of performing tests and conducting investigations of Weld-Metal. Sales experience. Member of American Welding Socy. and American Socy. for Metals. Good Linguist. Consider position outside U. S. Available July First. Address box MA-6, care of METALS & ALLOYS, 330 W. 42nd Street, New York, N. Y.

MARKET RESEARCH SPECIALIST with a good technical background. Complete developing and marketing experience on electrical and chemical specialties and instruments. Salary or fee basis. Box MA-9, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

METALLURGIST, TESTING, OR RESEARCH ENGINEER POSITION WANTED: Age 29. Five years' experience in physical metallurgy, metallography, material testing, including fatigue, at temperatures from +70° F. to —50° F., metal inspection, and design of special testing machine equipment. Some experience in heat treating. University graduate, M. S. degree. Now employed on nearly completed investigation. Available on or before Jan. 1st. Box MA-10, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

AVAILABLE — METALLURGIST — Technical graduate—35 years—8 years metallurgical supervision over all phases of special steel manufacture, including melting. Address Box MA-11, c/o METALS & ALLOYS, 330 West 42nd St., New York, N. Y.

REPRESENTATIVE WANTED: Industrial furnace manufacturer wants experienced sales engineer familiar with middle west territory and with some metallurgical knowledge. Commission basis. Address Box MA-12, c/o METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

WANTED: By large, well-known buyer of Metal Alloys and Residues containing Nickel, Chrome, Etc.—Representatives who are acquainted with the Steel—Chemical—Heat Treating, Heat Resisting, and Automobile Industries. We offer a very attractive proposition to the right man. Reply, giving references and qualifications. Also, cities and states which you cover. All references and qualifications will be kept strictly confidential. Box MA-13, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

WELDING ENGINEER, metallurgical experience with sales background. Experience in design, estimating and research, sheet metal and heavy structures. Not actively employed at present. Permanent connection desired. Box MA-14, care of METALS & ALLOYS, 330 West 42nd St., New York, N. Y.

METALLURGIST, immediately available. Technical graduate, studied under Dr. Albert Sauveur and Dr. V. N. Krivobok. 3 years of practical experience in research on failures, development and plant control of alloy and plain carbon steels. Also 3 years of experience in ore dressing and mining engineering. Single, 33 years of age, no preference to location. Address Box MA-15, METALS & ALLOYS, 330 W. 42nd St., New York.

METALLURGIST available. A young Dutch metallurgist, now employed in the laboratory of a machine and chain works in Holland, wants to get a chance in the U. S. A., with opportunities for increased responsibility and salary. Box MA-16, METALS & ALLOYS, 330 W. 42nd St., New York.

CURRENT NEWS ITEMS

A.F.A. Chooses Milwaukee for 1937 Convention and Exposition

Milwaukee, one of the foremost foundry centers in the United States, has been selected for the 41st annual convention and exposition of the American Foundrymen's Association, to be held during the week of May 3, 1937. The meetings and display of equipment and supplies will be staged in the Milwaukee Auditorium.

The board of directors, in selecting Milwaukee for the 1937 gathering of the foundry industry, gave recognition to the progressive Milwaukee Chapter. The interest and activity of the foundrymen of that section has placed Wisconsin in high rank in technical attendance and in handling the practical problems of foundry practice, apprentice training, cost, safety and hygiene. Outstanding plants, making all classes of castings, will be available for inspection.

Milwaukee is eminently suited for the activities planned. Hotel accommodations have been greatly expanded since the last previous A. F. A. convention held there in 1924. The auditorium, often cited as a model of such structures, and located within walking distance of the business and hotel section of the city, has full facilities for technical and committee meetings and for exhibits of equipment and supplies used in the foundry industry.

New Building for Battelle

The trustees of Battelle Memorial Institute, Columbus, Ohio, have announced the start of a building program to provide additional facilities for industrial research. Ground for a new building which will contain approximately 25,000 sq. ft. was broken on Oct. 5, and it is expected that it will be ready for occupancy shortly after the first of the year. The divisions of process metallurgy, ore dressing and coal processing will be housed in the new building which has been designed to accommodate the heavy equipment necessary for commercial scale foundry work and ore handling.

Nickel Company's Research Laboratory in England

Robert C. Stanley, president of The International Nickel Co. of Canada, Ltd., has announced the formal opening of the company's new research and development laboratory at Birmingham, England. Among those participating in the ceremony were the Lord Mayor of Birmingham and several officers and directors of the company, including Lord Weir, Lord Melchett, Sir Harry McGowan, Dr. John F. Thompson, executive vice-president, and D. Owen Evans, M.P., who is a vice-president of the parent company and delegate director of The Mond Nickel Co., Ltd., which forms its English division.

Additions to Battelle's Staff

D. A. Roberts, formerly with the W. E. Mowry Co. of St. Paul, and E. E. Slowter, formerly with the Pittsburgh Plate Glass Co., have accepted positions on the staff of Battelle Memorial Institute, Columbus, Ohio. Mr. Roberts will work on various phases of research in metallurgy and Mr. Slowter in chemical industry.

Metallurgical Service for South America

E. F. Feely, representative of The International Nickel Co. in South America, and J. S. Vanick, a member of the Development and Research Division, New York, are visiting several South American countries within the next few months in order to offer consultation service to industrial executives and engineers on problems involved in the production and application of nickel alloys. Both men are metallurgists and qualified by training and experience to provide valuable assistance in an advisory capacity.

Welding Authority Is Honored

Henry M. Hobart, for the past 25 yrs. a consulting engineer with the General Electric Co. at Schenectady, N. Y., was presented with the Samuel Wylie Miller Memorial Medal in recognition of his outstanding service in the advancement of welding research at the annual meeting of the American Welding Society, October 19, in Cleveland.

Mr. Hobart, an authority on arc welding, was a member of the welding committee formed by the United States Shipping Board at the time of the World War. He is a director of the American Welding Society, and chairman of the fundamental research committee of the Engineering Foundation Welding Research Board.

Chemical Industry Medal to Dr. Landis

The Chemical Industry Medal for 1936 was presented Nov. 6 to Dr. Walter S. Landis of the American Cyanamid Co. at a joint meeting of the American Section of the Society of Chemical Industry and the American Chemical Society, held at The Chemists' Club, New York. Dr. M. C. Whitaker first spoke on the accomplishments of the medalist and then the presentation of the medal was made by Dr. D. D. Jackson of Columbia University. In accepting the medal, Dr. Landis told about the developments in the fertilizer industry, the subject of his paper being "Concentrated Fertilizers."

Personals

Paul S. Lane, chief metallurgist of the Koppers Co., American Hammered Piston Ring Division, Baltimore, has assumed his new duties as metallurgical research engineer. A new physical testing laboratory and enlarged dynamometer room has recently been completed to permit of more extensive research into piston ring and engine problems. Mr. Lane is secretary-treasurer of the Baltimore Chapter, American Society for Metals, and a member of the American Foundrymen's Association and the Society of Automotive Engineers.

Eugene J. Ash, formerly of the Bureau of Standards, the Naval Gun Factory and the Watertown Arsenal, has assumed the position of teaching the metallurgy of cast metals in the department of metal processing in the college of engineering of the University of Michigan.

Lewis B. Lindemuth, New York, has just returned from England where he is engaged as consulting engineer for Richard Thomas & Co., Ltd., in connection with their expansion program. Mr. Lindemuth sails for Australia in November where he goes each year as consultant for the Broken Hill Proprietary Co., Ltd.

J. C. Chaston, abstractor for METALS AND ALLOYS, has been appointed senior lecturer in metallurgy at the Royal Technical College, Glasgow.

J. W. Weitzenkorn, former president of the Molybdenum Corp. of America, has become associated with the **Ohio Ferro-Alloys Corp.,** at Canton, Ohio, as director of research.

Election of **Frank Malcolm Farmer,** vice-president and chief engineer of the Electrical Testing Laboratories, New York, as chairman of the **Engineering Foundation,** research organization of the national engineering societies, is announced. Mr. Farmer, an authority on electrical measurements, electrical insulating materials, testing of engineering materials, and high voltage cables, succeeds H. P. Charlesworth, assistant chief engineer of the American Telephone & Telegraph Co.

A. E. Gibson, vice president, Wellman Engineering Co., Cleveland, has been elected president of the American Welding Society for 1936-1937.

MANUFACTURERS' LITERATURE

Potentiometer Control Pyrometer

The principles, operating details and methods of application of the Stabilog Potentiometer Control Pyrometer are described in Bulletin 194-1. Related equipment for automatic temperature control is also covered. The Foxboro Co., Foxboro, Mass. (1192)

Sand Control in the Foundry

A colorful pamphlet lists the major causes of casting defects and inferiorities and states that they may be avoided by the use of the proper sand control equipment. Illustrated. Harry W. Dietert Co., Detroit, Mich. (1193)

Stainless and Heat Resisting Steels

The application of stainless steels in the process industries is the subject of an attractive, illustrated, brochure. Physical and mechanical properties of the various grades of the corporation's stainless are included. United States Steel Corp. Subsidiaries, Pittsburgh, Pa. (1194)

X-Ray and the Foundry

Interesting treatise on this subject setting forth how the X-ray has now come to the fore as a tool of the testing laboratory. Kelley-Koett Mfg. Co., Inc., Covington, Ky. (1195)

Chapmanizing

A pamphlet devoted to Chapmanizing, which is a process of hardening low-carbon steel, compares it to nitriding and carburizing. The Chapman Valve Mfg. Co., Indian Orchard, Mass. (1196)

Spectrometric Equipment

Catalog D-221 is devoted to the above equipment. Basic theory and designs are described as well as the various types of instruments. Illustrated. Bausch & Lomb Optical Co., Rochester, N. Y. (1197)

Properties of OFHC Copper

An attractive booklet contains reprints of three papers relating to the above subject. Photographs, diagrams and photomicrographs are used to illustrate them. United States Metals Refining Co., New York, N. Y. (1198)

Salt Bath Furnace

The Ajax-Hultgren electrically heated salt bath was designed to meet the metallurgical requirements of liquid heat treating operations. Bulletin 103 lists some of the advantages of the furnace. Illustrated. Ajax Electric Co., Inc., Philadelphia, Pa. (1199)

Furnaces

Information concerning Hausfeld modern melting equipment for die casting is featured in an illustrated leaflet. These furnaces are made interchangeable for oil or gas fuel. Campbell-Hausfeld Co., Harrison, O. (1200)

Alloy Castings

Corrosion resistant and stainless steel castings are the subject of a new booklet. Chemical and metallurgical properties of these castings are included. Illustrated. Michiana Products Corp., Michigan City, Ind. (1201)

Modern Metal Treatment

A colorful pamphlet lists the R & H chemicals available for heat-treating, electroplating and for cleaning metals. E. I. du Pont de Nemours & Co., Inc., Wilmington, Del. (1202)

Optical Pyrometer

The Burrell optical pyrometer, a direct reading instrument originally designed for use with the Barrett fusion furnace and equally useful for other work requiring an optical pyrometer with a temperature range from 1500 to 3000 deg. F., is described and illustrated in a leaflet published by the Burrell Technical Supply Co., Pittsburgh, Pa. (1203)

Hardening Control

Useful information regarding case hardening steel is contained in a booklet of the A. F. Holden Co., New Haven, Conn. (1204)

Zinc Alloy Die Castings

A technical booklet tells the story of the development of the "Zamak" alloys. Tables and illustrations. New Jersey Zinc Co., New York, N. Y. (1205)

Special Atmospheres in the Heat Treatment and Brazing of Metals

A reprint of the above article by C. L. West, Research Engineer, is offered by The Electric Furnace Co., Salem, O. (1206)

Enduro

Data on the welding of Enduro stainless steels are given in a colorful brochure. Electric arc, gas, spot and projection, seam, flash, atomic hydrogen welding and brazing and silver soldering are features of this discussion. Republic Steel Corp., Massillon, O. (1207)

Phosphor Bronze

A leaflet lists the sizes in which the company's twelve-inch stock bushing bars are now offered. The Phosphor-Bronze Smelting Co., Philadelphia, Pa. (1208)

Sixteen Sins of the Cleaning Room

Are listed in a circular for convenience in checking on cleaning rooms. Great Lakes Foundry Sand Co., Detroit, Mich. (1209)

Free Cutting Steel

An attractive booklet records fifteen years spent by the company's metallurgical department in research on the machinability of free cutting steels. Jones & Laughlin Steel Corp., Pittsburgh, Pa. (1210)

Value of Draft Control

Bulletin No. L-125 is devoted to the above subject and points out the proper value of the furnace draft and this company's control which consists of a draft switch, a damper motor and a manual station. Illustrated. Shallcross Controls, Inc., Milwaukee, Wis. (1211)

Ampco Metal

Engineering data of a general nature is offered in Catalog No. 21. Technical explanations have been written so that the layman may understand them. It is claimed that this metal is a "process metal" and not just "another special bronze." Illustrations. Ampco Metal, Inc., Milwaukee, Wis. (1212)

Electromet Review

This publication, whose purpose is to bring "News and Views of Alloy Steels and Irons" to the reader, contains interesting items. Electro Metallurgical Co., New York, N. Y. (1213)

What Scientists Say of Leitz Ultropak

Bulletin No. 17 describes the personal experiences and applications to which Ultropak has been placed by scientific workers in various fields. E. Leitz, Inc., New York, N. Y. (1214)

Centrifugal Compressors

Bulletin 386 is devoted to this company's Design 9 Compressors. Illustrated. B. F. Sturtevant Co., Boston, Mass. (1215)

Mallory Elkon

Looseleaf catalog containing engineering data with descriptions, illustrations and recommendations for the selection of electrical contacts for all types of service. P. R. Mallory & Co., Inc., Indianapolis, Ind. (1216)

Liquitol

Bulletin A1-16-A deals with the use of Liquitol for iron and steel castings and ingots. Alpha-Lux Co., Inc., New York, N. Y. (1217)

Dowmetal Data Book

A new edition of this book, containing especially significant accomplishments since the last data book, in the sections. Available Forms and Shop Practice has been published by The Dow Chemical Co., Midland, Mich. (1218)

Sonittep Products

This booklet discusses heat loss and its control. The advantages of Sonittep insulating cement and its uses are listed. Instructions for its application are included. Graphs. George F. Pettinos, Inc., Philadelphia, Pa. (1219)

Surface Hardening by Induction

The TOCCO Process which, it is claimed, reduces hours of surface-hardening time to seconds and produces a scientifically regulated, exact result, is discussed in an attractive illustrated leaflet of The Ohio Crankshaft Co., Cleveland, O. (1220)

Inhibitor

Grasselli 3 inhibitor for efficient, economical pickling is the subject of a booklet of The Grasselli Chemical Co., Inc., Cleveland, O. (1221)

Electro-Granodizing

This process which, according to the manufacturers, provides a rust-proof, paint-receptive surface combining the advantages and eliminating the disadvantages of other protective coatings in commercial use today is described in an illustrated leaflet of the American Chemical Paint Co., Ambler, Pa. (1222)

Heat Exchanger

Bulletin No. 173 describes the Duriron heat exchanger which is available in the company's corrosion-resisting alloys—Duriron, Durichlor, Durimet, Durco Alloy Steel and Alcumite. Illustrated. Duriron Co., Dayton, O. (1223)

Ferrocarbo

This material containing both silicon and carbon combined in the form of silicon carbide acts as a graphitizer or softener when added to cast iron. Carborundum Co., Niagara Falls, N. Y. (1224)

Cor-Ten and Man-Ten

Pamphlet describing high-tensile steels developed to meet the needs of the transportation industry. United States Steel Corp., Pittsburgh, Pa. (1225)

MANUFACTURERS' LITERATURE

Silico-Manganese Spring Steel

Extreme care is taken in processing this steel to avoid imperfections, in rolling to obtain cold-shearing qualities and in controlling the uniformity of the structure to insure both high inherent fatigue resistance and uniform heat treating characteristics, according to the manufacturer. Illustrated. Bethlehem Steel Co., Bethlehem, Pa. (1226)

Fire Clay Products

A folder contains brief descriptions of the Goose Lake products and Therm-O-flake (for high temperature insulation) products. Illinois Clay Products Co., Joliet, Ill. (1227)

Coreless Induction Furnace

A colorful leaflet contains an explanation of the principles of operation and advantages to be obtained from the use of the Ajax-Northrup electric furnaces. Ajax Electrothermic Corp., Trenton, N. J. (1228)

Drop Forging Topics

Interesting articles are included in this illustrated publication of the Drop Forging Association, Cleveland, O. (1229)

Micromax Thermocouple Pyrometers

A new catalog, N-33A, explains the potentiometer method of measurement, the operation of the mechanisms through which this balance method is made available to industry. The complete line of instruments is set forth. Leeds & Northrup Co., Philadelphia, Pa. (1230)

Bolts, Nuts, Screws and Washers

A very complete catalog and price list of the above products is offered by The H. M. Harper Co., Chicago, Ill. (1231)

Aerocase

Booklet on this subject. Illustrations, curve charts, tables. American Cyanamid and Chemical Corp., New York., N. Y. (1232)

Yoloy

A colorful bulletin summarizes the properties of the above alloy steel and lists the physical properties of two typical steels in the Yoloy series. It is claimed to be corrosion resistant and to have high tensile strength and high ductility. Youngstown Sheet and Tube Co., Youngstown, O. (1233)

Furnace Element Construction

Bulletin HD-636 describes the development of the Hevi Duty element construction in furnaces. Some of the features of these elements are: freely radiated heat from the heating coils; coils are free to expand and contract; and tolerances are allowed for the free expansion of the radiant plates and tee supports and for normal growth of the coils. Hevi Duty Electric Co., Milwaukee, Wis. (1234)

Konik

Data on this steel's physical properties, corrosion resistance and working are offered by the Continental Steel Corp., Kokomo, Ind. (1235)

Armco H.T.-50

An illustrated folder devoted to the above alloy steel contains data on the average physical properties, corrosion resistance and forming and welding qualities. American Rolling Mill Co., Middletown, O. (1236)

Car Hearth Furnaces

Bulletin C-736 is devoted to these furnaces which were designed for uniform heating, sturdy construction and fuel economy. They can be built to use fuel oil, city gas, natural gas, butane or propane as fuel. Illustrated. The Philadelphia Drying Machinery Co., Philadelphia, Pa. (1237)

Granite City Hi-Yield 1 and 2

This company offers two types of high elastic steel which may be ordered in the regular or corrosion resistant grade. These steels are recommended for use, where abrasion resistance is required. Granite City Steel Co., Granite City, Ill. (1238)

High Temperature Insulation

For all types of heated equipment is the subject of an illustrated leaflet issued by Armstrong Cork Products Co., Lancaster, Pa. (1239)

Alloy Steels

A colorful folder devoted to these steels lists some of the advantages to be obtained by their use. Bliss & Laughlin, Inc., Harvey, Ill. (1240)

Electric Furnaces

A pamphlet describes the "Certain Curtain" furnace which was developed for heat treating at temperatures between 1850 and 2500 deg. F. C. I. Hayes, Inc., Providence, R. I. (1241)

Combination Impact Tester

This machine will make either izod, charpy, or tension tests quickly and accurately, and with minimum operator effort according to an illustrated pamphlet which is issued by the Riehle Testing Machine Div. of American Machine and Metals, Inc., East Moline, Ill. (1242)

Braze-Rite Furnace

This furnace, developed principally for brazing sintered carbide cutting tools, provides for localized heat to be applied only to the portion of the tool to be brazed. Illustrated. Firth-Sterling Steel Co., McKeesport, Pa. (1243)

Controlled Grain Anodes

Seymour Nickel Anodes are homogeneous in grain structure, according to this bulletin. The various available shapes are illustrated and some useful data are given. The Seymour Manufacturing Co., Seymour, Conn. (1244)

Centrifugal Castings

Bulletin C-2 is devoted to these castings which are available in the same analyses as the stationary-cast range of heat and corrosion resistant alloys which they supplement. Michigan Steel Casting Co., Detroit, Mich. (1245)

Multi-Rotary Table

The Wheelabrator multi-rotary table—the airless abrasive method of cleaning fragile or intricate metal parts—is described in Folder No. 33. Illustrated. The American Foundry Equipment Co., Mishawaka, Ind. (1246)

Heat and Corrosion Resistant Alloys Heated By Gas

Bulletin C1-A illustrates a number of complex castings made from Q-Alloys which are recommended for pipe fittings, furnace parts, etc. General Alloys Co., South Boston, Mass. (1247)

Brazing Alloys

The results of both laboratory and actual production data are contained in Bulletin No. 1 entitled "How to Use 'Handy' Silver Solders, Sil-Fos and Easy-Flo Brazing Alloys." Handy & Harman, New York, N. Y. (1248)

Fluxing, Deoxidizing and Hardening Alloys

Ajax alloys (phosphor copper, phosphor tin, nickel copper, manganese copper and silicon copper) are the subjects of a new leaflet issued by the Ajax Metal Co., Philadelphia, Pa. (1249)

Cutting Oils

A leaflet is devoted to the EFHCut series of oils. E. F. Houghton & Co., Philadelphia, Pa. (1250)

Stainless Steel Castings

An attractive booklet contains useful information on the subject. Typical analyses, characteristics and suggested uses are listed. Joseph T. Ryerson & Son, Inc., Chicago, Ill. (1251)

Bimetal

A simplified version of its manufacture and the way it works is contained in this pamphlet. W. M. Chace Co., Detroit, Mich. (1252)

3300 Deg. Super Refractory

An illustrated catalog devoted to "Shamva" Mullite contains information regarding its background, characteristics and uses. Mullite Refractories Co., Shelton, Conn. (1253)

Electric Welding Products

Catalog No. 101 contains information on welding rods (recommended uses for the different types, physical properties, welding procedure, etc.); miscellaneous apparatus, and Wilson arc welding machines. Air Reduction Sales Co., New York, N. Y. (1254)

Superficial Hardness Tester

Catalog Supplement RS-3 is devoted to this hardness tester, which is a special purpose machine, intended exclusively for hardness tests where only very shallow penetration is possible and where it is desired to know the hardness of the specimen close to the surface. Wilson Mechanical Instrument Co., New York, N. Y. (1255)

Firit

This protective coating for heat resisting parts used in foundries, steel and malleable plants, coke ovens, glass and ceramic plants, etc., is the subject of a leaflet. Foundry Services, Inc., New York, N. Y. (1256)

A. W. 70-90

This bulletin describes the new high-strength "70-90" steel in sheets and plates. An article on the engineering aspects of high-strength sheet steels is included. Alan Wood Steel Co., Conshohocken, Pa. (1257)

Application of Heat to Core Baking

A profusely illustrated booklet containing information resulting from research on the subject has been published by the American Gas Association, New York, N. Y. (1258)

Purifying Molten Iron

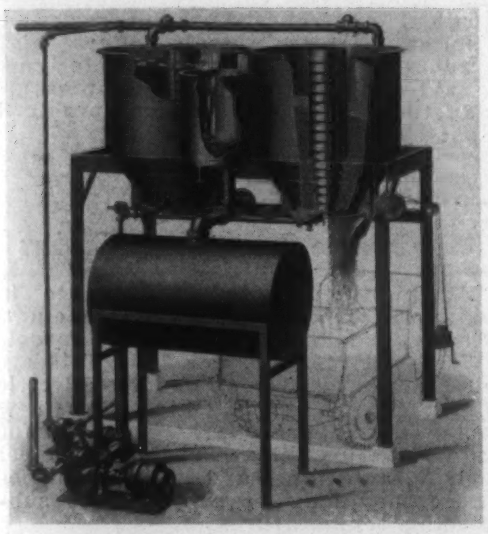
An iron finishing compound which is used in the pouring ladle for improving the castings is described in a pamphlet of The Maluminum Co., Indianapolis, Ind. (1259)

NEW EQUIPMENT AND MATERIALS

Multi-Louver Dewatering Tanks

The Claude B. Schneible Co., Chicago, announces a complete line of dewatering tanks for use with wet dust collector units. This new equipment known as the Schneible "Multi-Louver Dewatering Tank" is a specially designed unit for dewatering the accumulated sludge in the settling cone of multi-wash dust collectors. It is simple in design, has no moving parts other than the discharge gates, has nothing to break or quickly wear, and requires no care or attention other than the opening and closing of the valves, and opening of the gates in the discharging of the solids.

The method of operation is simple. Water containing solids enters the dewatering tank at the top through a baffled section which prevents undue disturbance of the water in the tank. A constant level is maintained in the tank at all times, the excess water flowing over a weir on the opposite side of the tank from the inlet. The overflow water enters a surge tank from where it is re-circulated in the dust collector system.



The low velocity of the water in the tank allows for complete precipitation of the solids in the area around the multi-louver cone in the center of the tank. When the tank is sufficiently filled with precipitated material, the inflow water is switched to another tank in the dewatering unit. After a short precipitation period, a valve on the line leading to the interior of the multi-louver cone is opened, and the head of water in the draining tank is allowed to recede slowly. The water flows out of the precipitated material and does not carry the material with it due to the angle of repose of the material against the multi-louver cones in the center of the tank. The final draining period will reduce the moisture contained in the sludge down to about 20 per cent, depending on the absorbent qualities of the material. When the sludge in the dewatering tank is completely drained, the bottom gates are dropped to allow the material to fill into a truck, railroad car, or other convenient receptacle.

Small rectangular tank dewaterers are used for use with installations where only a small amount of sludge is developed—railroad car type equipment being available for very large installations.

"HydroLectric" High Speed Presses

The Wood "HydroLectric" high speed presses are designed by the R. D. Wood Co., Philadelphia, for economic forming, stamping and drawing of metal sheets and also for straightening of malleable or steel castings and other heavy pressing operations.

Their speeds are said to equal or even exceed those of mechanical power presses, while maintaining all the advantages of hydraulic presses, via smoothness of operation, variable daylight and stroke adjustments to suit the work on hand, prevention of press or die breakage due to improper adjustments or over-loading, less rejects and better products.

The variable pressure and variable delivery, rotary piston pump is direct connected to an electric motor, both mounted on a rigid combination base and located close to the pre-fill tank. This type of pump with its controls permits quick changes of press tonnage and slide speed. As oil is being used as a pressure fluid, this has the additional advantage of preventing corrosion and freezing up, at the same time keeping all working surfaces and packings well lubricated. If a "dwell" on the work is required, an adjustable time delay is mounted on the press which automatically holds the full press on the work—for the length of time to which it has been set—before the slide automatically returns to its top position.

The press control is usually arranged for a semi-automatic cycle started by a hand lever or foot treadle and causing the press slide to make a complete approach, high pressure, and return stroke. However, if so desired, a full automatic cycle control can be furnished. With this control the press when once set in motion will repeat the above cycle over and over again until stopped by the operator, or set to a semi-automatic cycle.

For deep drawing these presses are preferably equipped with a hydraulic die cushion located in the press bed. This provides a means for clamping the blank, thus preventing wrinkling or tearing of the same during drawing operation. Die changes can be made quickly as no accurate adjustment of daylight or stroke is necessary and a convenient stroke control for die setting is provided.

Dowmetal for Hoover Castings

Dowmetal, the magnesium alloy rated one-third lighter than aluminum, invades the household appliance field for the first time with the announcement that the Hoover Company will use the metal in a newly developed vacuum cleaner.

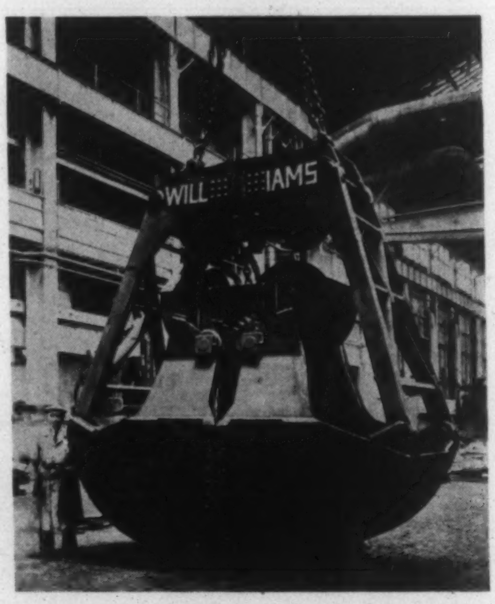
The announcement follows five years of experiments by Hoover and Dow Chemical Company engineers and the solution of vexing die-casting problems that have hitherto handicapped broad commercial applications.

New equipment and machinery to handle the metal has been installed at the Hoover plant at North Canton, Ohio, and the company is now turning out 5,000 castings a day. It is understood that extreme lightness will be one of the main sales points of the new cleaner.

Buckets of Low-Alloy High-Elastic Steel

The problem of handling seven tons of coal on a machine designed for six tons capacity has been solved in a 7-ton capacity "Williams" breakdown coal bucket recently constructed by The Wellman Engineering Co. of Cleveland for the Buffalo General Electric Co., which has placed the bucket in service unloading lake coal shipments at Buffalo.

Fabricated entirely of a nickel-copper alloy steel, "Yoloy," produced by The Youngstown Sheet & Tube Co., the bucket has jaws with a 16-ft. reach and grabs 8½ cu. yds. at one bite. Tests indicate that the steel has a resistance to atmospheric corrosion four to six times that of ordinary carbon steel, and possesses high resistance to impact both in the plate and weld. The bucket itself weighs 18,000 lbs. and has a yield strength above 60,000 lbs. and an ultimate strength of 90,000 lbs. per sq. in.



The Wellman company has also made use of this alloy in production of three cubic yard "Williams" clam shell buckets for handling zinc ore. A substantial increase in pay load has been made possible by holding weight of the bucket to 9,100 lbs.

An Aluminum De-gaser

To obtain perfectly sound aluminum castings it is essential to eliminate the gases already in the metal. After long, scientific research, the Foseco laboratories have perfected "Aluminum De-Gaser" to meet this need. It replaces the general method of applying such gases as chlorine or nitrogen, is more effective, convenient, simpler, and not dangerous to use. The Foseco Aluminum De-Gaser, based on the purifying effect of certain inert gases which are not soluble in aluminum, eliminates pinholes, removes gases present in metal or alloy, and improves the physical properties. It increases tensile strength 2 to 5,000 lbs. per sq. in., and shows an improvement in elongation of 20 to 30 per cent. It also improves the physical properties of silicon alloys when used before "modification." It is put out by Foundry Services, Inc., New York.

"Arcoloy," A Patented Metal

With the development of "Arcoloy," a new patented metal used for the manufacture of range boilers and storage tanks, the American Radiator Co., New York, announces the completion of the all-copper domestic hot water supply system. This development follows the introduction by this company within the past two years of a complete line of copper fittings for the complete copper in heating installation and it makes possible the use of a copper storage tank in radiator conditioning installations that include a domestic hot water supply.

Arcoloy range boilers and storage tanks for domestic hot water are made of 95 per cent pure copper with silicon, phosphor and other elements added to make a metal alloy which develops a corrosion-resisting skin when contacted by acids or alkalis. Arcoloy is said to have a higher resistance to ordinary corrosive agents than pure copper.

The rated gallon capacity of Arcoloy storange tanks is 25, 30, 40, 50, 60, 80 and 100 gal., while the range boilers are made with 25, 30, and 40 gal. capacities. All the tappings of both the boiler and storage tank are 1 in. iron pipe size.

Developed in the laboratories of the Products Development Division of the American Radiator Co., Arcoloy tanks and boilers have been field and laboratory tested for the past two years for resistance to corrosive material and for tensile strength. Sulphuric, nitric and other volatile acids and alkaline agents had practically no effect on the metal, and the tensile strength for ordinary boiler purposes averages from 55,000 to 65,000 lbs. per sq. in.

In all Arcoloy tanks and boilers no solder or any other metal is used in the construction. The tanks and boilers, guaranteed for 20 years against all normal water conditions and use, are electrically welded with Arcoloy welding rod and the spuds are made from forged Arcoloy.

Timken Sicromo Steels

To enable engineers and operators to achieve the economic balance essential to minimum production costs in refinery and other high temperature operations, The Timken Steel & Tube Co., Canton, Ohio, has developed a new series of steels, to be known as Sicromo 1, 2, 3 and 5. These new Timken high temperature steels extend the economic possibilities outlined by Timken DM Steel, the first Si-Cr-Mo alloy offered for high temperature use. Sicromo steels contain the 0.50 per cent Mo which has been found to be most effective for increasing creep strength on an economic basis. Their high silicon content develops the desired degree of oxidation resistance while economic resistance to corrosion is assured by the varying percentages of chromium indicated by the numbers.

Sicromo 1, 2 and 3 are particularly suitable for use in high temperature applications where low to medium oxidation and corrosion resistance is required. Sicromo 5 is designed for use where severe corrosion and oxidation is encountered, yet where equipment cost must be held to the minimum consistent with economic life and efficient operation.

Produced in electric furnaces under the most rigid chemical and metallurgical control, this new series of Timken Sicromo steels offers high grade, dependable alloy steels designed to aid those in the high temperature industries solve their tubing problems most economically.

New Freeze-Proof Water Coolers

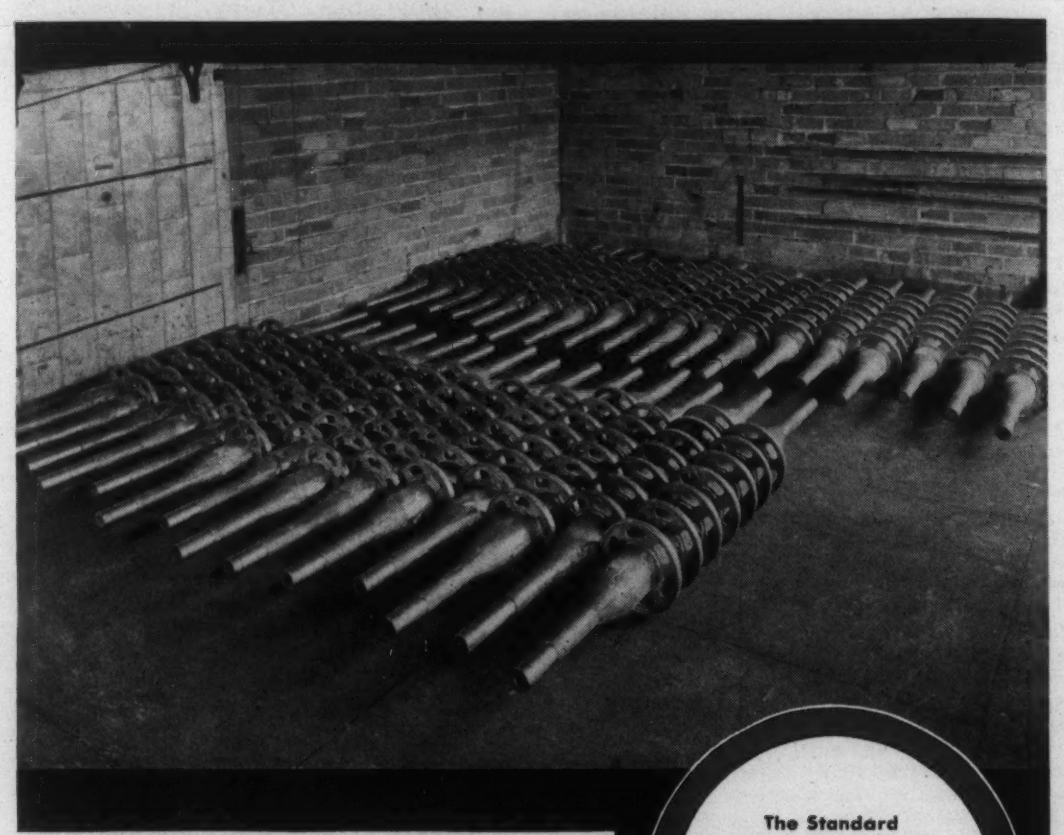
Especially designed to operate in temperatures below freezing, three new "Freeze-Proof" Water Coolers, models FWPF-8, FWPF-65, and FWPF-14 are announced by Westinghouse Electric & Mfg. Co., Mansfield, Ohio. These new coolers are particularly suitable for general industrial use such as in steel mills, factories, and other places where they may be subjected to subfreezing temperatures.

The coolers are especially insulated and equipped with thermostatically controlled Corox heating elements, mounted in the lower part of the cabinet. With this arrangement, these coolers will operate without freezing in temperatures as low as 20 deg. F. below zero. The model FWPF-65 Cooler has a capacity to cool 9.5 gal. of water per hour, from 70 to 50 deg.; the FWPF-8 Cooler delivers 11.9 gal.; and the FWPF-14 Cooler, 14.4 gal. per hr, under similar conditions.

An outstanding feature of these coolers is an improved type of dual-action cooling, eliminating the conventional type of pre-cooler, with its subsequent clogged drainage trouble. The dual-action principle is made possible by wrapping the incoming water line around the outside of the evaporator shell, to take advantage of the cold produced at the point to pre-cool the incoming water. This construction permits the use of a ¾ in. drain large enough to eliminate any possibility of clogging, which runs directly from the drain at the top of the cooler to the outside drain line.

Another exclusive feature in these new Westinghouse coolers, is incorporated in the cooling of motor, compressor, and condenser, by means of water. This water cooling system provides for increased capacity and freedom from clogged condensors.

All of these coolers carry a 5-yr. protection guarantee, and hermetically-sealed in mechanism, which consists of the motor and compressor sealed in an air tight armor of steel, with a lifetime supply of oil.



The Standard method of casting the central section insures uniformity in metal thickness and eliminates machining of the outside diameter of the shaft.

Standard Dry Shafts for Normalizing Furnaces

ARE you contending with the inefficiency of water-cooled shafting? An instance of much to lose and nothing to gain—certainly.

Standard Alloy Dry Shafts eliminate the expense and nuisance of water, as well as the attendant heat loss. Being centrifugally cast, they are straight, solid, homogeneous, uniform in thickness, nonwarping, free from inclusions. The end bearings are separate and sometimes can be used again.

Savings of 25% in fuel alone are typical. Why not record these economies in your 1937 profit column?

STANDARD ALLOY COMPANY, Inc.
1679 Collamer Road Cleveland, Ohio

Standard invites your correspondence relative to the manufacture of high grade heat-resisting alloy castings.

Standard service is based upon sound specialization. Standard pours only nickel chrome alloy.

STANDARD Heat-Resisting CASTINGS
NICKEL CHROME ALLOY

Extended Range of Fafnir Roller Bearings

A complete series of heavy-duty industrial roller bearings, made in an extended range of almost a hundred sizes, is now being manufactured by The Fafnir Bearing Co., New Britain, Conn. The rated capacity of these bearings ranges from 10,000 to 500,000 lbs., depending upon size, speed and loading conditions. The series is said to cope fully with the severe service requirements of paper mills, steel mills, and other heavy metal-working machinery, rubber and oil field equipment, and the like.

In the widened range of bearing sizes, rollers of ¾ in., 1¼ in. and 1½ in. diameter have been utilized, in addition to the 1 1/16 in. diameter used in the bearings previously available. A choice of 18 different bores is now offered in bearings of this type.

A feature of these roller bearings is the large number of solid rolls which are incorporated in the cage assembly, thus making for increased load capacity. The cage itself is fabricated from specially form-rolled spacer bar stock, with carburized and hardened end rings. Rollers are held in place and guided by spacer bars rather than by rivets through the rolls themselves, which of necessity tend to weaken the capacity of the roll. The spacer bars of the Fafnir cage are riveted to the end ring, and the accurate assembly of these bars keeps the rolls permanently aligned.

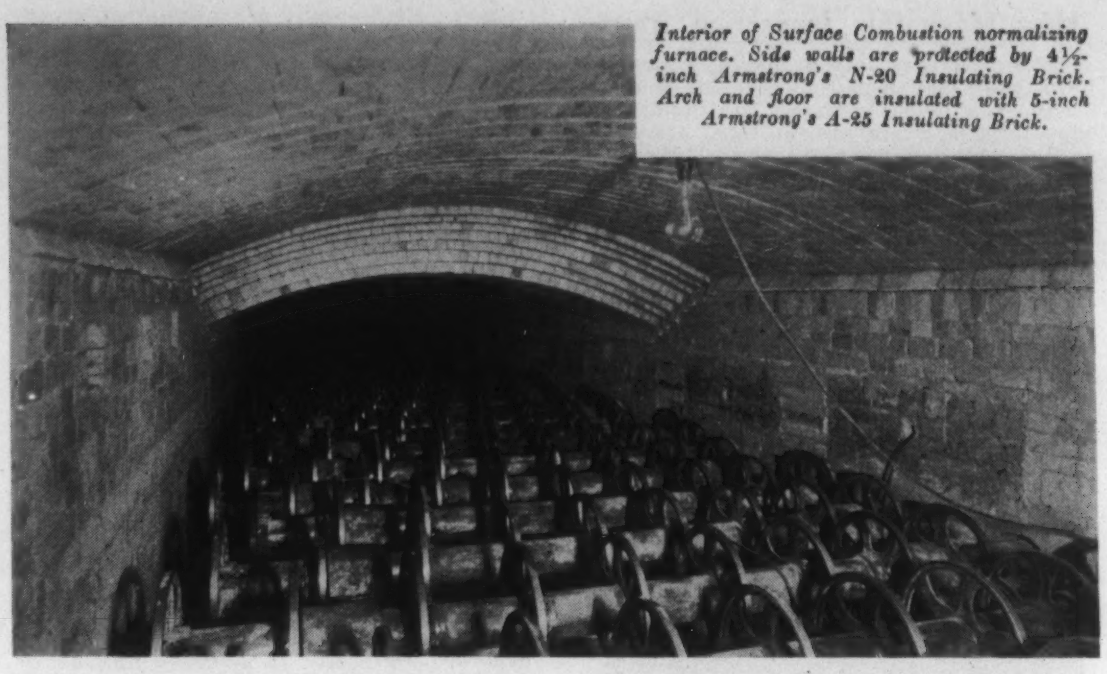
The entire roller assembly is made with a fixed radial clearance to allow for the expansion which takes place when the inner ring is shrunk to the shaft, this being the standard method of mounting for the roller type bearing. This clearance likewise permits the bearing to operate successfully and without impairment should temperature differentials occur in actual operation—that is, a certain amount of expansion due to heat, as is the case with dryer rolls, for example, can be taken care of without seriously affecting the relationship of the bearing parts.

All parts of these roller bearings are precision-ground, and held to extremely close tolerances. Complete specifications, including dimensions, tolerances and load ratings, are available on request.

A Metal Marking Machine

The Quality Dye Co., of 9314 S. Baltimore Ave., South Chicago, has introduced a new multiple wheel (non-automatic) metal marking machine, having features which offer the following advantages: All mechanism completely enclosed; instant changing of serial readings; turning of one wheel at a time while others remain locked, and positive locking of all wheels, once serials are selected, insuring proper alignment.

The machine is particularly desirable for serial marking in steel mills, foundries, forge-shops, machine shops and other heavy duty service in production plants. The wheels are made of tool steel and hardened. The numerical digits are deeply engraved on the circumference of the wheel and will withstand use on metal up to 415 Brinnell hardness. Characters to be stamped can be arranged in a straight line in any combination. Indicators are provided to locate position of marking. Impressions are made by hammerblow. The machines are available with four or more wheels and with figures ranging in size from 1-16 to ¼ in. or over. Literature is available by addressing the manufacturer.



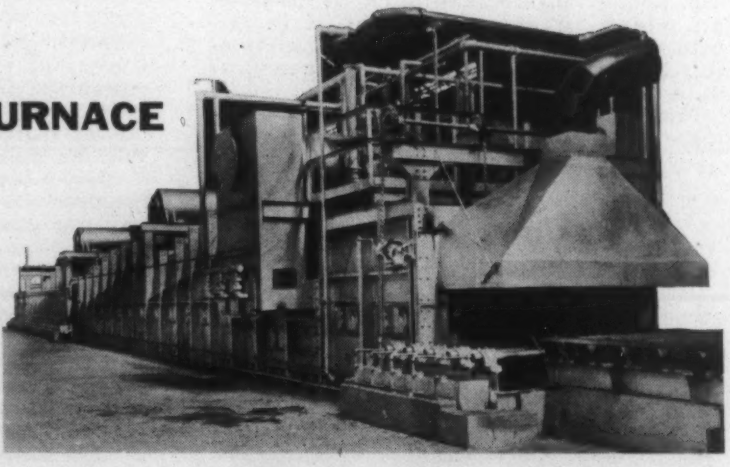
Interior of Surface Combustion normalizing furnace. Side walls are protected by 4½-inch Armstrong's N-20 Insulating Brick. Arch and floor are insulated with 5-inch Armstrong's A-25 Insulating Brick.

ARMSTRONG'S BRICK HELP MAINTAIN

Close, Accurate Temperature Control

IN THIS GIANT

NORMALIZING FURNACE



Surface Combustion's new furnace serves double duty. When normalizing, it operates at 1,900° F., and can turn out 21,800 lbs. of tin plate per hr. And when used as a blue annealer, it operates at 1,650° F., with a capacity of 38,000 lbs. per hr.

THIS new S C disc type normalizing furnace, built by the Surface Combustion Company, of Toledo, Ohio, is believed to be the widest dry shaft furnace of its kind.

In its operation, Armstrong's N-20 and A-25 Insulating Brick help maintain constant, uniform temperatures, and guard effectively against B.t.u. losses. Behind a refractory, Armstrong's N-20 shows no shrinkage at 2,000° F., at which temperature it has a crushing strength of 300 lbs. per sq. in. Armstrong's A-25 will not crack, fuse, or spall, behind a refractory, at temperatures as high as 2,500° F. Its crushing strength is 225 lbs. per sq. in. when cold, 265 lbs. at 1,800° F., and 91 lbs. at 2,100° F.

Armstrong also manufactures N-16 Insulating Brick for temperatures up to 1,600° F., and two Insulating Fire Brick—EF-22 and EF-26—semi-refractory brick for temperatures up to 2,200° F., and 2,600° F., respectively. Write for new descriptive folder. Armstrong Cork Products Co., Building Materials Div., 982 Concord St., Lancaster, Pa.

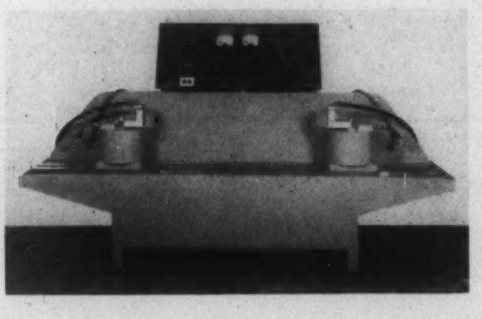
Armstrong's

HIGH TEMPERATURE PRODUCTS

New Magnaflux Inspection Units

Two new production inspection units have been developed by the Magnaflux Corp., New York., during the past year especially for the automotive, aircraft, and machine parts industries. Magnaflux unit D-301 operates on 60 cycle alternating current and is adapted to the detection of defects regardless of the direction in which they occur. This unit can be used for both magnetizing and demagnetizing the part. It also has an added advantage in that it is operated by a foot pedal. The magnetizing heads may be adjusted to accomodate parts up to 72 in. long.

Magnaflux unit DY-703 has been designed particularly for the inspection of crankshafts of larger size than can be accommodated in the D-701 unit. This unit can also be used for magnetizing and demagnetizing and it is also provided with an open grill table top underneath which is constructed a receiving tank. This permits the inspection of the part by the wet method without removing the part from the unit. The Magnaflux bath liquid is flowed over the part and collected in the receiving tank.



Rotary Louvre Dryers Now a Link-Belt Product

Announcement is made by Link-Belt Co., 300 W. Pershing Road, Chicago, that it has acquired the manufacturing and sales rights for North America, for the Dunford & Elliott rotary louvre dryer, of which many installations have been made in Europe, Canada and Japan.

It is being offered for the drying of all types of granular materials, coarse or fine, or of irregular shape, size and consistency; all types of crystals and powders manufactured or used in the chemical industry; factory refuse and waste; vegetable products, etc. It has also been employed as a heating or cooling unit; as a general reaction vessel; and for evaporating liquids on a solid substance. Among the materials handled are coal, coke, clay, fertilizers, grain, ores, cereals, salt, sand, sugar, wood chips and bark, cement clinker and all manner of chemicals.

The dryer is described briefly as a mechanically rotated horizontal drum with a series of internal channels near the circumference, into which hot air is admitted from a fan. These channels are covered by tangential plates which overlap in such a way as to leave a gap for hot air to pass from the channels into the inside of the drum and into the material contained therein, and at the same time prevent any material from falling backwards. The channels are tapered so as to give the inner lining of the drum a gentle slope from the feed end to the discharge end. As the drum revolves, fresh channels come underneath the charge, but, as the hot air can only enter the channels when they are actually underneath the charge, all the gases must pass upwards through the bed of material.

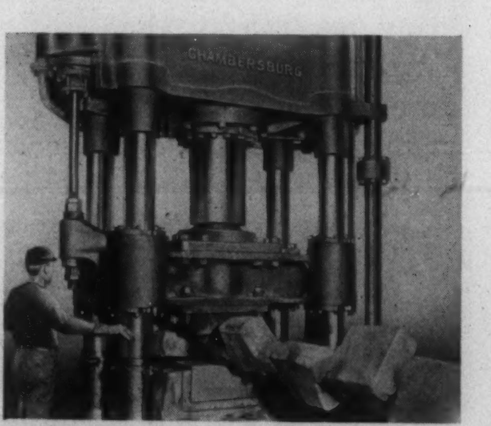
High-Speed Forging Press

Heavy forgings are forged quickly and economically to a close degree of accuracy by the high-speed steam-hydraulic forging presses recently added to the line of the Chambersburg Engineering Co., Chambersburg, Pa. These presses are manufactured and sold by the Chambersburg company by arrangement with the United Engineering & Foundry Co., Pittsburgh, Pa., and under Davy Bros., Ltd., patents.

The Chambersburg "United" steam-hydraulic forging press is built in two general styles: The single-frame and the four-column models. Both embody the same principles and application, the difference being only in capacity and physical features. The essential elements are the press, the steam intensifier and the water reservoir or prefiller tank.

Close control of the intensifier or forging stroke is attained by a controlling gear attached to the intensifier which operates to close the steam valve at a point of the intensifier stroke corresponding to the position of the hand lever. Thus a slow movement of the hand lever results in a correspondingly slow squeeze of the press, and stopping the movement arrests the action of the press. This gives the operator complete control of the action of the machine, a particularly valuable feature when cutting off or when a bending operation is being performed.

The single-frame press is built in 150-ton and 500-ton sizes. This type is particularly suitable for railroad and other repair shops where a variety of bending, forming and forging operations are performed. The four-column model is built as a single-cylinder press up to the 1500-ton size and as a duplex ram press from 2000-ton capacity upwards.

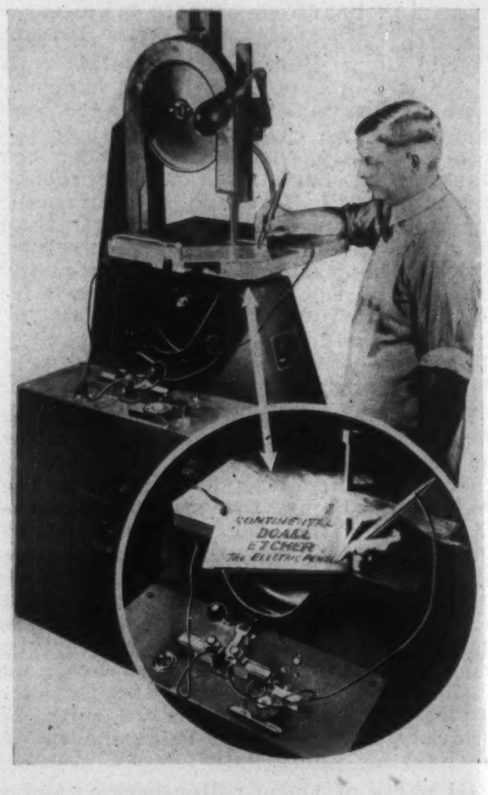


These presses embody a patented steam saving device, utilizing exhausting steam for useful work at the beginning of the following lifting or pressing stroke, produces a saving in steam consumption averaging 25 per cent of the consumption of any other make of steam intensifier. Another valuable feature of this system is a marked increase in speed of operation.

Doall Etching Pencil

A new "electric pencil" known as the "Doall Etcher" has just been placed on the market by Continental Machine Specialties, Inc., of Minneapolis, Minn. Writing on steel, with the electric pencil, is a process of arc welding, in which the tip of the pencil vibrates to permit the miniature arc to be interrupted and produce the etching effect.

In the Doall Etcher an entirely new principle is used to accomplish the vibration of the point of the pencil. A special coil in the pencil is attached directly on to the writing point. The point is made of pure tungsten to resist heat and wear. The pencil is operated from the transformer built into the company's Doall sawing, filing, and polishing machine. The principal function of this transformer is to weld or braze the precision metal cutting band saws used in the machine. The brazing transformer is especially suited to the requirements of the electric pencil, because it has low voltage and high amperage; the current being regulated with a 3-"heat" switch, shown in the lower illustration. Thus any desired degree of intensity for the etching arc may be attained.



The Doall Etching pencil is furnished with Doall machines. The slogan "takes the job right through" is borne out to completion with the addition of this new product. This machine tool now not only fabricates a piece from a roughing out to final polish, but marks the piece for identification.

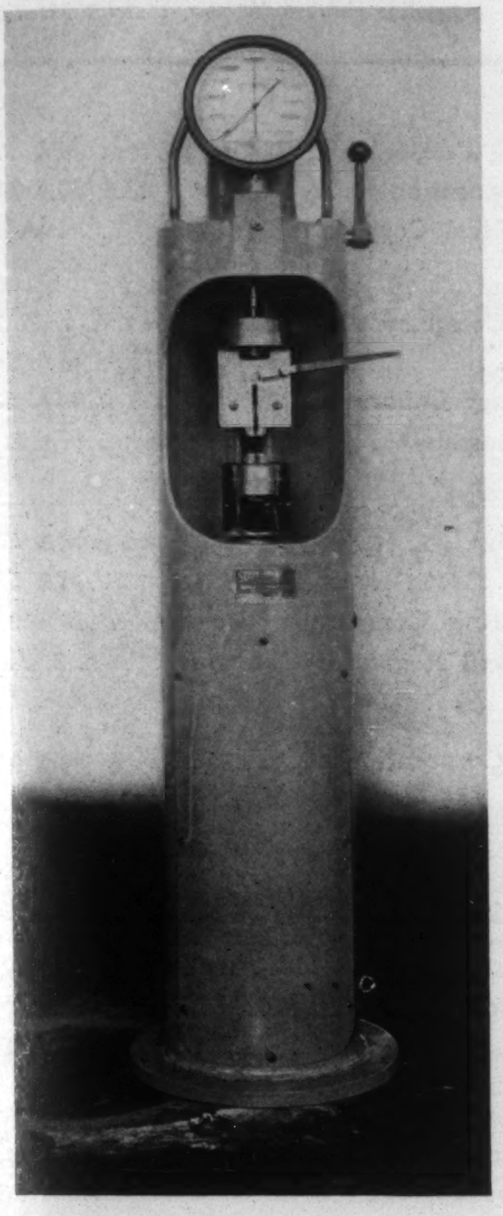
Acme Colored Superstrip Strip Steel

Acme Steel Co., Chicago, announces "Acme Colorstrip"—cold rolled strip steel in colors. Practically all colors and shades can be reproduced. Of particular interest to users is that the small extra cost of this attractive lacquered strip steel is only a fraction of the cost to produce the same effect on the product after forming.

Acme Colorstrip (as it is termed) will withstand bending, drawing and forming. Hence considerable interest in this new product is anticipated. This new departure, it is believed, will have an important bearing on product cost which has had to be colored after forming. This expense will be avoided with Acme Colorstrip.

Spot Weld Testing Machine

A new hydraulic machine for accurately testing the strength of spot welds has been developed and built by the Baldwin-Southwark Corp. of Philadelphia for the Edw. G. Budd Mfg. Co., Philadelphia, well known manufacturers of the streamlined Zephyr trains and automobile bodies.



This completely new 10,000-lb. hydraulic tension testing machine is of the most modern design and its rugged, fool-proof design makes it an invaluable piece of equipment where constant testing to insure proper welding strength is necessitated. The machine is supplied with a round base for rolling from place to place and a hoisting hook for moving with a crane. With an overall height of 70 in., an 18-in. diameter steel base, a low center of gravity, and weighing approximately 800 lbs., this completely self-contained spot weld tester is ideal for portable service. An 8-in. precision dial indicates the load. The cylinder is located at the top of the machine and has a 4½-in. diameter ram with a 2-in. stroke. Fluid under pressure is pumped by a gear pump situated in the base of the machine. This pump is direct connected to a ¼ h.p. motor.

A specially designed type of self-aligning, lever operated, renewable file-face grips is used. These grips are so designed that hard sharp faces can be quickly installed at a very low cost, being made of short sections of machine cut files. The upper grip is of the open face type, while the lower grip is of the closed type with wide angle entrance. These grips will accommodate offsets in welded specimens from the smallest gage to ¼-in. thick without using backing plates or liners. Specimens up to 1¼-in. wide can be tested. Balanced grip holders are cut from solid blocks of high carbon steel. Top and bottom handling levers are set at right angles, thus affording convenient operation. All working parts of the machine are easily accessible by removing the front cover plate. Although primarily intended for the services above, the Southwark spot weld tester is a convenient and inexpensive machine for all sorts of tensile testing.

Bright Zinc Plating

A more extensive use of zinc plating for production of attractive and durable rust-resistant surfaces on a wide variety of steel articles has been made possible through development, by the R. & H. Chemicals Department of the du Pont company, of an improved barrel plating process which uses a new brightening agent. The new process is claimed to be particularly adaptable to use in barrel plating of building hardware, radio parts, electrical fixtures and other metal equipment where attractive appearance is important. It is said to be quite resistant to finger staining.

The product and the process have been thoroughly tested and are now being used with success by a number of commercial plating establishments. This new and brighter zinc plating is a natural extension of the first commercial and practical process for bright zinc plating which was brought out by the du Pont company about a year ago meeting the immediate need for an inexpensive, durable, decorative metal surface for steel articles.

All of the practical and economic advantages of the original bright zinc plating are retained in the modified method. Only small quantities of the new brightener are introduced into the regular plating solutions. No radical changes in plating practices are involved. Flat and irregular or deeply recessed steel articles are given a high uniform luster. This brighter deposit, like that obtained with the old process, also resists corrosion.

The new brightener is a liquid, easy to handle and control. In addition to being non-corrosive, it is non-inflammable and non-toxic. Consequently, it adds no complications or hazards to the bright zinc process while meeting the demand for a protective finish high in appearance value.

Two Plastic Refractory Materials

Two new plastic refractory materials, known as "Champion Furnace Patch" and "Champion Ramming Mix," especially developed for high temperature melting furnaces, are announced by the Champion Spark Plug Co. and the Detroit Electric Furnace Co., Detroit, from whom they may be obtained.

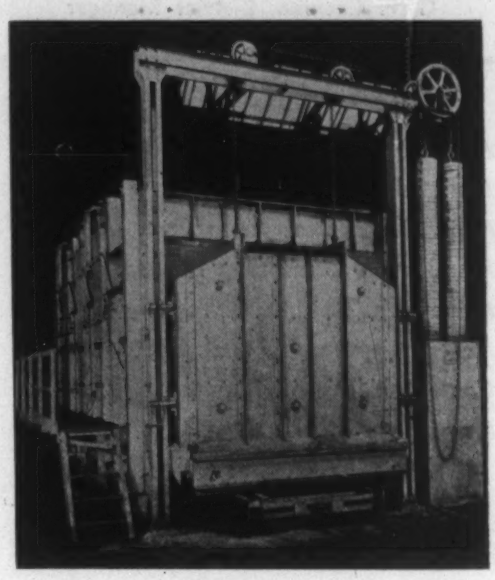
Ceramic engineers of the Champion Spark Plug Co. have developed a plasticizing process for andalusite base mullite. The results are available in two forms, a plastic ramming mix and a plastic patch or cement. The materials are similar chemically but differ in screen size, the ramming mix being of coarser texture, adapted for ramming deep patches or monolithic linings.

Champion refractories have been in use by scores of electric furnace users for a number of years. This recent improvement lowers the labor cost of the installation and secures for the user a better and longer lasting refractory. Prices of the new refractory have also been reduced.

"Plastic Mix" and "Plastic Patch" have been field tested in a number of difficult melting operations. Uniformly favorable results have been reported by users.

A Car Hearth Furnace

Car hearth furnaces of improved design and materials are producing high fuel economy, uniform temperature distribution, close control of both temperature and atmosphere with wide range of temperature operation allowing for several heat treatments in the same furnace, with low first and operating costs. Two or more cars can be supplied for continuous furnace operation. Standard "PDM" combustion equipment can be supplied for oil, gas (artificial or natural) and propane. This includes burners, automatic temperature and furnace pressure controls. Alloy hoods or covers can be supplied for special atmospheres during the heating and cooling cycle. Hoods, with or without insulation, can be supplied for controlled cooling. This furnace is a product of the Philadelphia Drying Machinery Co., Philadelphia.



A Box Type Furnace

PDM box type furnaces of improved design and material, offer high fuel economy, uniform temperature distribution, close control, wide range of temperature operation allowing for several heat treatments in the same furnace, with low first and operating costs, and are manufactured in 18 standard sizes by the Philadelphia Drying Machinery Co., Philadelphia. They can be supplied with oil, gas or propane burner equipment, also automatic temperature and atmosphere control, and with insulating refractory brick or fire brick linings.

1. ORE CONCENTRATION

JOHN ATTWOOD, SECTION EDITOR

Ore Dressing Research—Results of Tests at Kalgoorlie and Melbourne. W. G. Clark. *Chemical Engineeering & Mining Review*, Vol. 28, June 8, 1936. Reports are reviewed of ore dressing tests on the following ores: (1) sulphide Au ore from Yellowdine mine, (2) Au ore from Weerianna and Nicol mines at Roebourne, W. A., (3) pyritic Au ore from Slippery Gimlet mine, W. A., (4) pyritic Au ore from Hill 50 mine at Mt. Magnet, W. A., (5) Au ore from Prohibition mine at Meekatharra, W. A., (6) complex Au ore from Snake Valley mine near Ballarat, Vic., and (7) sulphide Au ore from Mt. Freda, Queensland. Cyanidation and flotation data are given. WHB (1)

Sluicing for Gold and Tin—The Operations of Cock's Pioneer. G. B. O'Malley. *Chemical Engineering & Mining Review*, Vol. 28, June 8, 1936, pages 289-294. An historical sketch and description of present sluicing operations. The yield and treatment costs of the present operating company are tabulated. WHB (1)

Milling Practice Little Long Lac Gold Mines Limited. Neville S. Spence. *Canadian Mining Journal*, Vol. 57, Aug. 1936, pages 363-70. Milling practice is outlined. The conclusions drawn from 3½ months' work are: (1) the arsenopyrite is the refractory Au-bearing mineral in the ore, (2) finer grinding will not liberate this Au nor will stronger cyanide dissolve it, (3) the Au in the arsenopyrite exists in some chemical or physical state such that it is bonded to its host mineral and it is due to a change in the physical characteristics of the mineral that the Au is amenable to cyanidation, (4) by removal of the sulphides from the present plant tailings, sweet roasting this concentrate, and then cyanidizing the roasted product, the overall extraction may be raised by about 5%, giving a total extraction over 92%. The flowsheets show the cyanide circuit, the refinery, the flotation of cyanide residues and the roaster calcine treatment. WHB (1)

Concentration of Loparite Ore. Ya. P. Kim. *Redkie Metallui*, Vol. 5, Jan.-Feb. 1936, pages 26-34. In Russian. This ore, containing the mineral loparite, contains 0.45% rare earths and 0.15% $Ta_2O_5 + Cb_2O_5$. Concentration on tables followed by magnetic treatment yielded a product containing 23.25% rare earths and 7.75% $Ta_2O_5 + Cb_2O_5$ with a recovery of 68%. HWR (1)

Loloma Treatment Plant—Roll Crushing, Drying, Roasting, Cyaniding. *Chemical Engineering & Mining Review*, Vol. 28, July 8, 1936, pages 347-350. The treatment of ore of the Loloma (Fiji) Gold Mines, Ltd., Tavau is outlined. The whole feed is roasted after fine crushing in rolls, followed by cyanidation of the calcine. The flowsheet and plan of the treatment plant are shown. WHB (1)

■ 1a. Crushing, Grinding & Plant Handling ■

Selection of Ore-Crushing and Grinding Equipment. Joseph E. Kennedy. *Mining & Metallurgy*, Vol. 17, Mar. 1936, pages 139-140. Discusses crushing and grinding equipment suitable for preparing run-of-mine ore for concentration, amalgamation, flotation, or cyanidation. Important factor is the tonnage to be dealt with. For large plants suggests a large jaw or gyratory crusher for reducing to 8"-10" or finer. In open pit work, using power shovels, jaw crusher should have an opening of 48" by 60", or 60" by 84". Best type of feeder to ball or rod mill is the disk. Special type of fine grinding gyratory permits the reduction of 2½" or of suitable character to as fine as 90 mesh or finer. Small size crushers are suitable for use in handling ore in closed circuit with classifier and a ball or rod mill. Belt conveyors are preferable to elevators. VSP (1a)

■ 1c. Flotation ■

Modernization Revives an Old Grass Valley Mine. John B. Huttl. *Engineering & Mining Journal*, Vol. 136, Mar. 1936, pages 145-146. A 3-year program of underground exploration and development, followed by erection of a modern flotation mill, rehabilitates the Spring Hill mine unworked nearly 60 years. WHB (1c)

1e. Amalgamation, Cyanidation & Leaching

Ore Treatment at the Reduction Works of the Transvaal Gold Mining Estates, Limited. C. G. Brink. *Journal Chemical, Metallurgical & Mining Society South Africa*, Vol. 36, Feb. 1936, pages 203-214. The ore at Central Mines contains graphite which, unless removed, causes premature precipitation of dissolved Au. Paraffin (0.4 lb./ton) added to the pulp in the tube mill floats off the graphite in the water overflowing the collectors. The paraffin has no injurious effect upon precipitation in the Zn boxes, nor does it retard amalgamation. Settlement of slimes is improved. Certain Cu ores, such as malachite, consume less cyanide after paraffin treatment. Lime added to the pulp after leaving the mill increases amalgamation recovery by 6%. Au recovery by amalgamation is 40%. Sand forms 18.5% of the tonnage, it receives 10 days treatment; 3 lbs. of dissolved $Pb(NO_3)_2$ is added to each new charge. The slime receives 22 hrs. agitation; concentration is maintained at 0.045% NaCN and 0.01% CaO. The long period of agitation is essential owing to the slowness with which the Au is dissolved in the presence of Cu and Ag. In strong cyanide solutions Cu interferes very little with the normal working of the Zn boxes, but if the free cyanide content is low, the Zn is coated with an adherent film of Cu and Au precipitation is reduced. Consumption of reagents, per ton milled, is Zn 0.36 lb., NaCN 2.5 and lime (65% available CaO) 12 lbs. Oxygenation reduces cyanide consumption and increases Cu and Ag recovery in the Zn boxes to 90%. Brief descriptions of flow sheets at 2 other mines are given. AHE (1e)

2. ORE REDUCTION

A. H. EMERY, SECTION EDITOR

■ 2a. Non-Ferrous ■

Direct Production of Electrolytic Copper Plates. *Metal Industry*, New York, Vol. 33, Nov. 1935, pages 395-396. Current density, voltage, $CuSO_4$ and acid content must be controlled in order to produce Cu plates by direct electrodeposition. Circulation of the electrolyte is necessary. CBJ (2a)

The Rhokana Electrolytic Copper Refinery. Archer E. Wheeler & Henry Y. Eagle. *Bulletin Institution Mining & Metallurgy*, No. 380, May 1936, pages 1-15. Discussion. See *Metals & Alloys*, Vol. 7, Aug. 1936, page MA 396R/4. AHE (2a)

Some Improvements on the Electrolytic Refining of Copper at Hitachi Mine. H. Isituka. *Journal of the Mining Institute of Japan*, Vol. 51, Nov. 1935, pages 677-690. The direct production of anodes from converter is preferred generally in Japan on account of the high cost of fuel compared to that of labor. Converter-anodes are classified according to the degree of blowing and the appearance of their surfaces as (A) an under-blown variety containing excess S, (B) a moderate one with 0.05% S and (C) an over-blown one with more than 0.5% S. (B) gives the best results with respect to power consumption (450 kw. hr./1 ton of Cu; formerly 600 kw. hr.) the rate of dissolution and the loss of Au and Ag. 55° C. is the best temperature for the electrolyte. Se extraction increased from 55% to 80% by the use of a special sublimation apparatus and Cottrell treaters. Blue vitriol crystals were made practically free from Fe (0.02% Fe). The hexa-hydrate method was adopted in the manufacture of $NiSO_4$ and the content of Zn diminished to 0.01%. YO (2a)

Novelty in Zinc Metallurgy (Nouveauté en métallurgie du zinc) O. Dony-Henault. *Revue de Métallurgie*, Vol. 3, July 1936, pages 422-426. Brief sketch dealing principally with New Jersey Zinc Co. distillation process. JDG (2a)

Making Ferromolybdenum without External Heat Application. *Kachestvennaia Stal*, Vol. 4, No. 2, 1936, page 55. In Russian. Roasted MoS_2 concentrate containing 68.3% MoO_3, 72% Fe-Si, CaF_2 and Fe scale was ground and thoroughly mixed. A sheet steel conical mold, containing a primer of 50 g. Al + 190 g. KNO_3 was imbedded in sand. After ignition with a Mg wire the mixture was added gradually. The alloy produced was sound and uniform, not differing in appearance from electric steel, and assayed 65% Mo, 0.01-0.10 C, 0.18-1.03 Si, traces to 0.1 S. 6 laboratory heats with 20 kg. each of MoO_3 and 5 semi-production heats using 150 kg. each of concentrate showed a general recovery of 94.5%. The following mixture is recommended for 65% alloy: 1.26 calcined concentrate (80-85% MoS_2), 0.5 of 72% Fe-Si, 0.3 Fe scale, 0.2% steel scrap, 0.15% fluorspar. (2a)

■ 2b. Ferrous ■

Iron and Steel. *Times [London] Trade & Engineering*, Vol. 38, Jan. 1936, page XVI. Review of British developments in plant and research during 1935. MS (2b)

Probable Development of Blast Furnace Lines (Le developpement probable du profil des haut fourneaux) E. Cotel. *Revue de Métallurgie*, Vol. 33, Apr. 1936, pages 253-257. Present biconical shape of blast furnace cross section is an unjustified survival of middle ages. Much evidence indicates that a total elimination of boshes and the use of a straight line profile is more advantageous than the present lines, particularly when the shaft flares upwards. Rachette type of furnace might come back. JDG (2b)

Arc Furnaces for Ferroalloy Production by Ore Reduction (Fours à arc pour la production de ferro-alliages par reduction des minerais) M. Kauchtschischwili. *Journal du Four Electrique*, Vol. 45, Apr. 1936, pages 125-126. Translation from *Siemens-Zeitschrift*. See *Metals & Alloys*, Vol. 6, July 1935, page MA 273R/8. JDG (2b)

Sponge Iron. *Foundry Trade Journal*, Vol. 54, Jan. 16, 1936, page 73. In a new German process for the manufacture of sponge Fe (D.R.P. 617942), Fe ore is briquetted (with a small amount of C if necessary) and reduced with CO, H or a mixture of these gases or other hydrocarbons, in a vertical or shaft furnace, in such a way that about halfway down the furnace the ore reaches its highest temperature, being then cooled to nearly atmospheric temperature by a cold blast of reducing gas admitted at the base of the furnace. The Fe is extracted from the furnace as sponge. Cooling before leaving the furnace is necessary to prevent the oxidation of the hot sponge on coming in contact with the air. AIK (2b)

Determination of Humidity of Dust-containing Gases (Die Bestimmung des Feuchtigkeitsgehaltes technischer staubhaltiger Gase) Alfred Schwartz. *Messtechnik*, Vol. 12, July 1936, pages 144-146. Electric psychrometers are suitable if they are enclosed in a dust-proof case. The application for blast-furnace gases is described. Ha (2b)

Making Alloy Steels Using Cast Irons Bearing Chromium and Nickel. A. K. Silin. *Kachestvennaia Stal*, Vol. 4, No. 4, 1936, pages 25-26. In Russian. High strength steels can be made directly in an open hearth furnace by using Fe rich in Ni and Cr. A run of 20 heats was made in a 20 ton basic open hearth furnace using Fe containing 0.7-0.8% Cr and 1.20% Ni. Good results could be obtained using a charge consisting of as much as 90% of this Fe. Cr is removed completely in the first slag. Then a lime slag is built and the heat finished as usual. Steels of SAE type 3115-3145 of good quality were produced without difficulty. (2b)

3. MELTING, REFINING AND CASTING

A Plea for Loam Moulding. Robert Liddle. *Foundry Trade Journal,* Vol. 54, Apr. 9, 1936, pages 283-286. Paper read before Scottish branch, Institute of British Foundrymen. Author believes that loam molding is very safe, and the castings produced equally good, when compared with those molded by other methods. Standardized equipment, cylinder molding, core-making, assembling the mold, core assembly, patternmaking, finishing operations, high-pressure cylinders in loam, template details, etc., are discussed by the author. AIK (3)

Modern Coreshop Production. W. H. Smith. *Foundry Trade Journal,* Vol. 54, Apr. 9, 1936, pages 279-281; Apr. 16, 1936, pages 301-303. Paper read before Birmingham branch, Institute of British Foundrymen. Reference is made to the principal elements in coreshop production and the methods adopted by a few of the more progressive foundries. In the opinion of the author, taking the industry as a whole, the coreshop has so far not received the consideration its importance in modern foundry production calls for. Sand distribution to coremakers, coreboxes, handling green sand cores, etc., are discussed. AIK (3)

Cores Made with Sulphite Liquor. I. A. Chistov. *Liteinoe Delo,* Vol. 7, No. 5, 1936, pages 13-14. In Russian. Sand mixture selected contained: 100% sand, 5-7% clay, 5-7% sulphite liquor (sp.g.1.3) and 1% heavy oil. Cores produced were much stronger than the average permitting elimination of steel reinforcements. (3)

Rational Shape of Sink Heads. D. A. Popov & B. N. Scherbachenko. *Liteinoe Delo,* Vol. 7, No. 5, 1936, pages 24-28. In Russian. Experiments conducted with casting stearine in sheet Fe molds indicate that the best efficiency of a sink head is obtained when the ratio of its volume to the surface is at a maximum. (3)

The Technique of Powder Metallurgy. Charles Hardy. *Mining & Metallurgy,* Vol. 17, Mar. 1936, pages 145-146. Abstract of a paper read before the Chicago section of the American Institute of Mining Engineers, Feb. 1936. Powder metallurgy is the production of semi- or fully formed metal products by compressing metal powders. Principal metal powders are produced by electrolysis or by reduction of metal oxides by gases. Purity of metal powder is of great importance, and also the control of particle structure, size and fineness. Compression of powder involves consideration of compression ratios, dies and presses. Density of pressed article is controlled by selection of the powder density and regulation of compression ratios. Dies are made of special die steels. Pressures used vary from 2 to 75 or 100 tons/in.^{2}. Compressed pieces are heat treated which is a sintering process. Gives various applications of compressed powders. VSP (3)

Core Prints. N. A. Sokolov. *Liteinoe Delo,* Vol. 7, No. 6, 1936, pages 23-25. In Russian. Standards recommended and adopted are given. (3)

A Laboratory Vacuum Casting Furnace. Jack H. Scaff & Earle E. Schumacher. *Metals & Alloys,* Vol. 7, Aug. 1936, pages 204-206. Describes laboratory apparatus for melting and casting metals under pressures of 0.01 to 0.08 mm. of Hg. Inductive melting is employed. WLC (3)

Composition and its Effect upon the Properties of Mould and Core-Sand Mixtures at Elevated Temperatures. F. Hudson. *Foundry Trade Journal,* Vol. 54, 1936, June 11, 1936, pages 458-460; June 25, 1936, pages 502-505, 510. Paper presented at the annual conference of the Institute of British Foundrymen in Glasgow. This paper is a continuation of a previous paper on "Some Properties of Mould and Core Materials at Elevated Temperatures" (*Foundry Trade Journal* Dec. 5, 1935). The following main points were brought out by this investigation: Many of the mold and core compositions used in the foundry trade have unsuitable properties at elevated temperatures. These unsuitable properties are characterized by excessive expansion and cracks, strains and inherent stresses, hot tears and pulls and dimensional inaccuracies between casting and pattern. The results obtained indicate that a certain coal-dust addition imparts the necessary properties at elevated temperature to green sand. Sawdust additions are most satisfactory for dry sand and loam. The paper also indicates the effect of other materials which can be alternatively added to promote better properties at elevated temperatures. The paper is illustrated with a number of diagrams. AIK (3)

Develops a New Type of Enclosed Hinge. *Foundry,* Vol. 64, June 1936, page 74. Describes a new type of hinge or knuckle joint developed by J. F. Hines Mfg. Co. Hinges may be cast in Al, brass, malleable Fe, steel, high test Fe, bakelite, etc. Can be made in any size or shape for use on seagoing vessels or railroad rolling stock. Principle is adapted for casting chains in Al, brass, steel, etc. Gives details of construction. VSP (3)

Cross Section of Sprues and Filtering Screens in Gating Systems. S. I. Bernstein. *Liteinoe Delo,* Vol. 7, No. 6, 1936, pages 17-19. In Russian. A series of experiments showed that the cross section of sprues can be reduced to almost 40% of that of the gates before the metal loses its head in casting. (3)

G. L. CRAIG, SECTION EDITOR

Practical Aspects of Die-Castings. N. G. D. Robertson. *Foundry Trade Journal,* Vol. 54, Apr. 23, 1936, pages 317, 318. Paper read before a joint meeting of the London branches of the Institute of Metals and British Foundrymen. Numerous machines have been designed for producing die-castings. In some of these the metal is forced into the die by a piston, in others by compressed air. In the vacuum process the metal is drawn into the die by applying a vacuum. The gravity process should not really be classified as a type of die-casting and the American term "permanent mold casting" is more suitable. Metals of high melting temperatures such as brass and bronze are now being cast by the pressure process. However, the surface of brass pressure castings is not in any way as good as in brass gravity castings, and certainly not as fine as in some of the alloys with lower melting points. Brass gravity die-castings are the most difficult to produce, except perhaps in very simple shapes. Pressure die-castings can be made to closer limits than gravity castings. Die-casting can seldom compete with sand casting in the production of castings that require no machining. See also *Metals & Alloys,* Vol. 7, Sept. 1936, page MA 440R/5. AIK (3a)

Inverse Segregation and the "Perspiration" (Tin Sweat) of Bronzes (La Segregazione Inversa e i "Trasudamenti" dei Bronzi) G. Somigli. *Industria Meccanica,* Vol. 18, June 1936, pages 347-355; July 1936, pages 424-434. According to new experiments, the cause of inverse segregation of bronze must be solely ascribed to the action of enclosed gas. The Ludwig-Soret effect, although theoretically valid, has no practical importance as there is not sufficient thermal gradient during the casting period for it to establish itself. The contraction accompanying solidification has an indirect effect only while the gases dissolved during melting and escaping during solidification determine, but do not regulate the intensity of inverse segregation. Contraction due to shrinking is not sufficient to determine the causes for perspiration (tin sweat) because sweating does not take place when the dissolution of gases is eliminated. The method of presolidification followed by remelting under suitable cover is practically sufficient to avoid inverse segregation even in bronzes with high P content. 25 references. Ha (3a)

Rules for Pouring Bearings with Babbitt metal (Leitregeln für das Ausgiessen von Lagerschalen mit Regelmetall) E. T. Richards. *Werkstatt und Betrieb,* Vol. 69, July 1936, pages 183-184. Failure of Babbitt is often attributed to the composition and general qualities of the Babbitt metal, but it also depends on a number of other circumstances such as pretreatment of the bushings, proper cleaning, etching, pickling and tinning. Pouring temperatures are: bushing 260°-300° C., Babbitt metal 350°-400° C., cores or mandrels with brass bushing 125°-150° C., with steel or cast Fe bushing 240°-250° C. Too cold mandrels cause hard and brittle surfaces of the Babbitt, too hot mandrels lead to too great diameter. Vibration should be avoided during solidification. HR (3a)

Evolution of Die Casting (L'evolution de la Coulée en Coquille) G. RIVOIRE. *Revue de Fonderie Moderne,* Vol. 30, Apr. 25, 1936, pages 138-140. A brief review of die casting, especially of Al, Al-Zn and Al-Cu, and of the development of the metal molds and possible further developments is given. Ha (3a)

Copper as a Mould Material. Applications in the Casting of Metals. A. J. MILLER. *Metal Industry,* London, Vol. 48, June 26, 1936, pages 705-710. I. General applications. Although molds of Cu were employed during the Bronze Age, it is only recently that Cu has been used extensively as a material for molds and bottom plates. The Cu-producing industry was the first to abandon cast Fe molds. Cu-bottom plates were used extensively in the latter part of the last century. The reactions between C and surface oxides, resulting in "blown" surfaces, was largely the reason for the substitution of Cu for Fe molds. The gradual method by which this substitution was made is indicated. The Junker water-cooled type, introduced about 1926, is considered as the first type of Cu-mold to be used economically. A more robust type, developed by the American Metal Co. in 1929, is made of solid Cu. II. Advantages of copper as a mold material. The high thermal conductivity of Cu is a major factor in making it a superior mold material. Cu of a high purity should be used as some impurities, such as As, when present even in very small quantities, tend to decrease this conductivity greatly. Advantages obtained are more uniform rate of solidification, improved surface of cast material, and longer service life of the molds. The behavior of different mold materials are compared. III. Description of Copper Molds and Bottom Plates used in Practice. Specific instances are cited in which the methods of using Cu-molds by different companies are described. These include (1) the casting of Cu in horizontal solid Cu-molds, (2) solid and water-cooled Cu-molds for vertically cast Cu-cakes, billets and wire bars, (3) Cu-molds for casting Cu-alloys, and (4) Cu-molds and bottom-plates for casting other metals. Illustrations showing various types of molds are included. 16 references. HBG (3a)

Founding Aluminum Bronze Castings. M. T. GANZAUGE. *Foundry,* Vol. 64, June 1936, pages 24-25, 82, 84. From paper read before the American Foundrymen's Association at Detroit. Deals with the practical phases of the founding of Al bronze for high pressure work. VSP (3a)

Cast Bronze Parts for Pumps. PAT DWYER. *Foundry,* Vol. 64, June 1936, pages 32-33, 90. Describes the production of rotary power driven pumps by the Northern Pump Co., Minneapolis. Gray Fe and steel castings are procured from local foundries, while non-ferrous castings are made by a subsidiary, the Northern Foundry Co. Bronze compositions are melted in 2-500 lb. capacity electric furnaces. To insure correct chemical and physical properties, over 25 standard alloys have been developed. Twin core ovens take care of the output of 5 coremakers. Products for the U. S. Navy, specification 46M6C, calls for minimum tensile strength of 40,000 lb./in.^{2}, minimum elongation of 20% in 2". The composition of metal is: Cu 86-89%; Sn 8.00-11.00%; Zn 1.00-3.00%; and impurities maximum 0.5% Special methods of molding, gating and feeding have been developed. VSP (3a)

Melting Magnesium Alloys in Gaseous Atmosphere. K. V. PEREDELSKI. *Liteinoe Delo,* Vol. 7, No. 5, 1936, pages 33-36. In Russian. Mg-Al alloys were melted under H_2 and H_2S. Physical properties of H_2 treated metal were slightly better than H_2S treated. No S inclusions were found under microscope, though analysis showed 0.03-0.04% S. (3a)

Some Factors which Influence Soundness in Non-ferrous Castings. A. LOGAN. *Proceedings Institute of British Foundrymen,* Vol. 28, 1934-1935, pages 683-706. See *Metals & Alloys,* Vol. 6, Oct. 1935, page MA 390. CEJ (3a)

Non-Ferrous Castings. A. LOGAN. *Foundry Trade Journal,* Vol. 54, Mar. 19, 1936, pages 231, 232, 234. Extended abstract of the paper which was read before the East Midlands Branch of the Institute of British Foundrymen. Methods of melting, cost of melting, development of light alloys, piston alloys, "Y" alloy, "R.R." alloys, ceralumin alloy, Al-Si and Mg alloys are discussed by the author. AIK (3a)

Investigations on the Casting of German Silvers (Recherches sur la Coulée des Maillechort) M. BALLAY & R. CHAVY. *Cuivre et Laiton,* Vol. 9, June 30, 1936, pages 271-276; July 30, 1936, pages 319-325. The properties and defects occurring in castings of Ni (German) silver are discussed and furnaces used for melting described. It is most important, in order to obtain a sound casting without gas inclusions, to add an easily oxidizing metal which eliminates the gas; Mg, Mn, Al, Si give good results. Al and Mg in excess, however, make the metal viscous. Mn avoids this inconvenience but is less active than Al. Good results are obtained with 0.3-0.5% Mn added as cupro-manganese (30% Mn), or metallic Mn. Al as metal or cupro-aluminum should be added in an amount of 0.02-0.03%. Addition of 0.3% Mn, followed by an addition of 0.015% Al as cupro-aluminum (50% Al) or even 10-15% Al is particularly recommended. The additions should be made when the pouring temperature has been attained but by no means before. Pouring temperature should be no less than 1250° C., and for low Zn contents at least 1350° C. Molding sands should be more refractory than for usual foundry purposes, and if the castings are used for decorative purposes, without machining, a fairly fine-grained sand should be employed. In order to accelerate cooling and to avoid porosity it is advisable to mix 3-5% graphite with the sand to increase its thermal conductivity. Molds and cores should be carefully baked; a sand consisting of 80% silicious and 20% yellow sand, agglomerated with linseed oil and dextrine is particularly suitable in this case. Practical hints for molding and casting are given. The corrosion resistance of Ni silver increases with Ni content. Alloys with 20% Ni and 5% Zn are used more frequently in America while in Europe the Zn content is usually 12-30%. Diagrams of hardness as a function of composition, and tables of mechanical properties are added. 20 references. Ha (3a)

Sand Casting Copper-Silicon Alloys, H. A. Bedworth & V. P. Weaver. *Foundry,* Vol. 64, July 1936, pages 24-26, 59. Alloys are principally Cu alloyed with Si plus one or more additions to enhance their properties, particularly those rendering them suitable for the manufacture of castings. Alloys are melted in crucible furnaces or in electric furnaces. During melting metal is protected by some gasless flux, such as ordinary bottle glass. Molding in general follows closely the practice used for gun metal. Cores are made from open, sharp sand with linseed oil binder. Molds should be rammed lightly to improve permeability. To secure sound castings metal should be poured rather hot and should have high sprues. Metal should be poured slowly especially in the case of large castings. Cu-Si alloys are readily machinable where proper procedure is followed. Cu-Si alloys are non-rusting. Includes a table giving the approximate physical properties of a 95% Cu, 4% Si and 1% Mn alloy. Slag Inclusions in Acid Steel. Yu. T. Lukashevich-Duvanova & P. S. Germant. *Kachestvennaia Stal,* Vol. 4, No. 3, 1936, pages 45-54. In Russian. 4 15-ton acid open hearth heats were comprehensively investigated in regard to their non-metallic inclusions. The latter were separated from the metal by dissolving in a mixture of 10% HNO_3 and 10% citric acid solutions, and electrolytically in a solution containing 3% $FeSO_4$, 1% NaCl and 0.2% ammonium citrate. They were studied under a microscope and analyzed by means of differentiated solution (Yu. T. Lukashevich-Duvanova, *Zavodskaia Laboratoria,* Nos. 1 and 2, 1934). Amount and type of inclusions produced during melting and present in the finished metal is about the same. The size of inclusions depends on the cooling rate. Slag is highly dispersed in the metal in molten state. The degree of dispersion or solubility of slag in molten metal is defined by slag concentration in the bath. On addition of deoxidizers character of slag inclusions changes slowly and gradually, within 30-40 minutes. Original slag is present in transparent globules of silicates changing on addition of deoxidizers to dark granular silicates. Al_2O_3 inclusions are present in the bath from the beginning as well as magnetic Fe oxide, observed in solidified samples. Distribution of slag along the depth of the bath is haphazard. (3b)

HAUSFELD MELTING FURNACES

Make Continuous Operation Possible

By installing this battery of six Hausfeld Tilting Crucible Furnaces, burning gas or oil, the cheapest known fuels, this manufacturing plant stepped up production of die casting metal to a point that called for a *conveyor to carry the load commonly carried slowly and at high cost by man power. Result—66 per cent increase in production with costs reduced in proportion.

If your melting costs are too high or your production too low, write us.

* *The Conveyor System shown is a Link Belt Installation*

SAVED

TWO LADLES

- Ladles lined the ordinary way, with a two-inch lining of clay and fire sand, hold 15% less metal than those lined the modern LUXIT way. This modern, many-purpose refractory cement gives you a ladle lining only three-quarters of an inch thick, but it holds heat longer than the ordinary lining.

In other words, eleven LUXIT-lined ladles hold more metal than thirteen old-fashioned ladles. You may save two ladles with LUXIT,—and eliminate the man power required to push them. But this saving is only half the story.

Here is the other half. LUXIT linings last from six to ten weeks. Contrast this with the life of ordinary linings. Here are savings in time and material that can be written in good black ink on the right side of the operating statement.

Try lining your ladles with LUXIT, and remember its many advantages when you

- Line or patch cupolas and furnaces,
- Lay brick in cupolas and ladles,
- Want an efficient slurry wash.

Let us give you further details on this modern refractory cement. . . . Write us today.

Production of Nickel-Chrome-Molybdenum Steel Castings from a Bessemer Converter. J. FLACK. *Foundry Trade Journal,* Vol. 54, May 21, 1936, page 399. An entry in the short paper competition held by the Birmingham branch of the Institute of British Foundrymen. Most of the Ni-Cr-Mo steels were made by the crucible, open-hearth or electric furnace processes, and the converter process was introduced experimentally, but proved so successful that it can now compete with the other processes as a commercial proposition. Plant, molding and foundry conditions, heat-treatment, structure and type of castings are discussed. AIK (3b)

Refining Iron to the Malleable Condition. WM. MCCONNACHIE. *Blast Furnace & Steel Plant,* Vol. 24, Feb. 1936, pages 141-144, 148. Discusses oxidation of metalloids in steel-making processes and the action of O_2 and H_2O in the blast in the Bessemer process. Free O_2 acts on everything with which it comes in contact. That part of the O_2 in the blast in the combined form oxidizes some C, Si, etc. but no Fe. Oxides of Fe produced by blast act on Si and perhaps Mn resulting in recovery of some of the oxidized Fe. In addition, CO and H_2 throw down more Fe from the oxides. If slaked CaO could be safely introduced with the blast, there would be greater yields, as the H_2O would act selectively on the impurities without oxidizing the Fe, while the H_2 formed could reduce the oxides produced. CaO would combine with the SiO_2, leaving FeO free to be reduced by Mn, Si, or C, and the gases. Slag consisting of Ca SiO_3 would be no more corrosive on the converter lining than the usual $FeSiO_3$ or $MnSiO_3$.

Soda Treatment in Iron Metallurgy (Le traitement sodique en sidérurgie. Observation. Résultats) ACHILLE G. LEFEBVRE. *Revue de Métallurgie,* Vol. 33, May 1936, pages 289-290. Na added to molten Fe forms very fusible slag which washes away non-metallic inclusions besides reducing S content. Granulated soda ash is preferably added when Fe is tapped from the blast furnaces, though it might be used in remelting. Original paper was presented at the Mining & Metallurgical Congress in Paris in Oct. 1935. JDG (3b)

A Defect in the Foundry: The "Egg Shell" (Un Défaut de Fonderie: La "Coquille d'Oeuf") GUY HÉNON. *Revue de Fonderie Moderne,* Vol. 30, Jan. 25, 1936, pages 19-23. "Egg shell" is the name of a defect in casting which consists in a very thin casting skin sticking to the surfaces of certain cored pieces; the skin is 0.5-1.0 mm. thick, and forms particularly on surfaces of an oval shape, whence the name. The study of this phenomenon showed that an accumulated amount of P is found in the shell and that the casting is pronouncedly pearlitic and has, therefore, a wide range of Ar transformation. Means to avoid this defect are (1) to make the solid layer on the core dense and uniform, the corners of the core should be cooled by cooling tubes. (2) A more ferritic than pearlitic structure is better as it has a lower expansion and therefore fills the mold better in cooling. (3) The solidification should take place isothermically by limiting the temperature interval between crust and core of the piece. The conditions are discussed at length and illustrated by micrographs. Ha (3b)

Properly Constructed Gate Delivers Clean Metal to the Mold. A. J. CASSISTA. *Foundry,* Vol. 64, Mar. 1936, pages 34, 78, 80. Describes various methods of pouring metal into mold to insure elimination of dirt and slag in castings. Considers various skimming equipment and its proper use. VSP (3b)

Benefits from Corrugated Molds. EMIL GATHMANN. *Blast Furnace & Steel Plant,* Vol. 24, Apr. 1936, pages 326-327. When corrugations are of suitable design, quality can be greatly improved and chipping costs reduced considerably for all types of steel. Salients should be made as deep as practical to obtain maximum volume of initial solidification, but yet sufficiently shallow to prevent occurrence of dangerous stresses during the shrinkage that takes place throughout solidification period, as well as to obviate excessive decarburization of surface during reheating. Mold walls must be of sufficient thickness and heat-absorptive value that there can be no appreciable distortion of mold-matrix contour at any time during entire period of ingot's solidification. Shows horizontal cross-section of a mold contour embodying these requirements. MS (3b)

Electric Reheating of Ingot and Casting Sink Heads (Réchauffage par l'arc électrique des masselottes des lingots et des moulages) LEOPOLD GRANGER. *Revue de Métallurgie,* Vol. 33, Apr. 1936, page 243. Application to the sink heads of electric arc of a small intensity, about 100 KW keeps the metal liquid and reduces losses to about 5% of the weight of ingots. The simplest electrical equipment is satisfactory. JDG (3b)

Cast Iron Pulleys for Wire Ropes (Report of the Wire Ropes Research Committee of the Institution of Mechanical Engineers) *Bulletin British Cast Iron Research Association,* Vol. 4, Oct. 1935, pages 214-217. Review of report. See *Metals & Alloys,* Vol. 7, June 1936, page MA 285L/1. WB (3b)

The Work of the Heterogeneity of Steel Ingots Committee. W. H. HATFIELD. *Iron & Steel Institute,* Special Report No. 12, May 1936, 43 pages; *Iron & Coal Trades Review,* Vol. 132, Apr. 3, 1936, pages 617-618; *Metal Progress,* Vol. 29, May 1936, pages 76, 83, 84, 86; *Iron & Steel Industry,* Vol. 9, Nov. 1935, pages 57-65. A summary of work previously reported by the Committee. The Committee was formed in 1924 and 6 reports, beginning in 1926, have been issued. One of the major findings of the Committee was that the character of the liquid steel resulting from the steel-making reactions determines the degree and nature of heterogeneity resulting from the mechanism of freezing. The contents of previous reports and descriptions of ingots studied are listed.

Manufacture of Cast Rolls (Gray Iron, Hard Castings, Steel Castings) (Ueber die Herstellung von Gusswalzen, Grauguss, Hartguss und Stahlguss) H. Jungbluth. *Technische Mitteilungen Krupp,* Vol. 4, Aug. 1936, pages 129-142. The characteristic differences of these 3 kinds of rolls are described. The hardness of hard castings is due to the content of cementite while in gray Fe a large part of the C has been precipitated as graphite. The various structural forms can be produced according to the following general rules: The graphite content increases with increasing C and Si for a given cooling velocity. The graphite content increases with decreasing cooling velocity for a given composition. The graphite content is reduced by accelerated cooling until eventually all graphite has disappeared and the Fe solidifies as white cast Fe. Rolls of cast steel are used almost exclusively in the U.S.A., very seldom in Europe. Types and compositions of rolls are described and methods of manufacture discussed. Application of the various types in rolling mills for definite processes is given in a table and the causes for fractures of rolls are discussed. 29 references. Ha (4a)

Measuring Rolling-Mill Pressures. A. L. Bement. *Electric Journal,* Vol. 33, Sept. 1936, pages 404-406. A magnetic strain gage is applied to mill stands to inform the operator as to the exact pressures between the rolls. Maximum reduction can thus be obtained with safety. Knowledge of the pressures makes possible the following: to have the pressure on both screws the same provided the steel entering the mill is uniform, to detect differences in thickness between the 2 sides of material entering the mill, to detect uneven roll cooling in hot mills which would result in loss of gage accuracy, to determine the proper division of load between stands of tandem mills for economical operation, and to determine and maintain the proper rolling pressure for materials subject to punishment by excessive rolling. CBJ (4a)

■ 4b. Forging & Extruding ■

A. W. DEMMLER, SECTION EDITOR

Forging and Heat Treating Locomotive Parts. J. B. Nealey. *Industrial Gas,* Vol. 15, July 1936, pages 15-17. See *Metals & Alloys,* Vol. 7, July 1936, page MA 344R/9. Ha (4b)

Forging the Light Alloys. J. Towns Robinson. *Metal Industry,* London, Vol. 48, Jan. 17, 1936, pages 87-91. Deals with the forging and stamping of the well-known light alloys such as Duralumin, "Y"-alloy and the Hiduminium R. R. series. It is advantageous to start with sound homogeneous ingots having a small and uniform crystal distribution. To do so not only makes possible easier working of the metal but also produces better ultimate results. The advantage of this type of structure over coarser columnar or a mixture of columnar and coarse equiaxed crystals is indicated. The author recommends a close inspection of ingots for defects. Round ingots are superior where the product is produced chiefly by compression and square ingots are used to better advantage when the material is to be elongated, reduced in cross-section and for stamping. Critical factors are (1) close control of soaking temperature, (2) procedure of the forging operation, and (3) shape and size of the dummy. Some precautions to be observed in stamping are indicated and the importance of recrystallization of extruded material is discussed. HBG (4b)

The Extrusion of Non-Ferrous Metals. A. Wragg. *Metal Industry,* London, Vol. 48, Jan. 17, 1936, pages 73-77. Author considers the recently developed extrusion process simply as a source of raw material. He discusses the products of this process as (1) rods, tubes and shapes for engineering purposes, (2) hot stamping stock, and (3) shapes and special sections. The 2 commonly used methods of extrusion are described, compared and the advantages of each are indicated. The design of the British type of press is compared with some types used on the Continent. Limits of size and shape of extruded material and the physical properties of a number of extruded alloys are discussed. The author gives as the 2 main limiting factors (a) that there must be no appreciable re-entrant angles which will require a tongue in the die, and (b) that the cross-section must be such that the flow of metal coming through the die is uniform along the section. HBG (4b)

Influence of Teeming Conditions on Forgeability of Chromium-Nickel Structural Steels. A. M. Pelevich & B. Kh. Sapir. *Kachestvennaia Stal,* Vol. 4, No. 5, 1936, pages 52-55. In Russian. A study of 133 heats of 0.15-0.22% C, 0.40 Si, 0.20-0.50 Mn, 0.8-1.2 W, 1.3-1.7 Cr, 4.0-4.7 Ni showed that exceptionally high losses due to ingots falling apart in forging were associated with teeming temperature and teeming time. The higher the temperature of the metal the slower must be the teeming which can be adjusted by varying the diameter of nozzles used. (4b)

■ 4c. Cold Working, including Shearing, Punching, Drawing & Stamping ■

The Deep Drawing of Sheet Metal. J. D. Jevons. *Metal Industry,* London, Vol. 48, Jan. 17, 1936, pages 67-72. Author states that during 1935 a study was begun of the fundamental principles of the process of deep drawing. He stresses the necessity for correlation of theory with practice and the need for a more practical, simple method of testing. He suggests as 4 principle fields for immediate study: (1) the fundamental principles underlying the behavior of plastic materials, (2) the interpretation and influence of "average grain size," (3) the causes of troubles experienced by the consumer, and (4) the elimination, by the producer, of those defects in his product which occasion most trouble to the consumer. The author believes that the importance of regularity in crystal size is underestimated. Only minor improvements in the manufacture of sheet were noted during the past year. Some of these are mentioned. Defects inherent in brass and sheet steel are considered. There are also mentioned as improvements of the past year that are wholly relevant to deep drawing, Cr-plating, food materials, the use of octagonal blanks, a better selection of lubricants, the elimination of inter-stage annealing and the deep drawing of plated sheet. HBG (4c)

Recent Developments in Steel Wire Technology. S. A. Braley. *Wire & Wire Products,* Vol. 11, July 1936, pages 323-325, 350-351. Fundamentals required for satisfactory production of steel wires with respect to chemical composition, crystal structure, physical properties and surface condition are discussed and proper coordination of research and plant is emphasized. Ha (4c)

New Researches on the Drawing of Cylindrical Shells. G. Sachs. *Journal Royal Aeronautical Society,* Vol. 39, Nov. 1935, pages 1081-1091; discussion, page 1092. The last decade has witnessed a great increase in the reduction obtainable in a single draw in deep-drawing operations. The results of several workers in this field are critically examined and correlated under the headings: drawing without and with sheet-weakening, tool form and drawing capacity, blank holder and drawing capacity, testing of sheet ductility, and the outlook for the future. 39 references. See also *Metals & Alloys,* Vol. 7, May 1936, page MA 232R/7. FPP (4c)

The Effect of Annealing on the Length of Cold-Drawn Rods. Kisuke Saito. *Science Reports Tohoku Imperial University,* Vol. 25, Apr. 1936, pages 128-140. See *Metals & Alloys,* Vol. 7, Aug. 1936, page MA 401L/9. BWG (4c)

Influence of Cold Drawing on Mechanical Properties and Internal Strains of Chromium-Silicon Steel. G. I. POGODIN. *Kachestvennaia Stal,* Vol. 4, No. 5, 1936, pages 41-46. In Russian. The steel under investigation contained 0.89% C, 1.13 Cr, 1.43 Si and was used as tool steel occupying an intermediate position between C tool steel and high speed. Hot rolled 10.9 mm. rods were properly annealed and then drawn to different extents through dies having the same reduction angle. A comprehensive investigation showed that hardness of samples increases towards the center. Low reduction gives a proportionally greater hardening. Tensile stresses are present at the outside of rods, compressive near the center. The maximum stress is present 0.50-0.75 mm. under the surface. Distribution law of strains in samples having different reduction is about the same, but absolute values vary. Mechanical strength is closely related to the changes of hardness across the cross-section of specimens. Toughness is inversely proportional to mechanical strength. (4c)

Coldworking of Ageable Aluminum Alloys (Spanlose Formgebung von aushärtbaren Aluminiumlegierungen) H. HORNAUER. *Werkstatt und Betrieb,* Vol. 69, May 1936, page 121. Survey of the different types of alloys, influence of temperature on tensile strength and workability. The forming of a C-shape from sheet by pressing, bending or drawing is illustrated. Sources of failures are discussed. HR (4c)

Deep Drawing Capacity of Pure Aluminum Sheets of Different Degrees of Hardness (Die Tiefziehfähigkeit von Reinaluminium-Blechen verschiedenen Härtegrades) WERNER HELLING. *Metallwirtschaft,* Vol. 15, Apr. 24, 1936, pages 388-394; May 1, 1936, pages 409-412. The deep-drawing capacity, evaluated by the ratio of the diameter of the form to that of the die, was determined for a large number of commercial pure Al sheets in the fully annealed, ¼, ½, ¾ and fully hardened state. It was shown that this could be predicted by the Erichsen value only when the tensile strength is also known. The power consumption increased, but only at the beginning of the draw, with increasing hardness of the starting material. The elasticity of the walls increased with the amount of rolling of the sheet, while the weight loss by polishing, and time required for polishing decreased. GD (4c)

Broaching Lead Composition Cylinders. ROGERS FISKE. *Iron Age,* Vol. 138, Aug. 13, 1936, pages 44-45. Describes method employed by the Goss Printing Press Co. in broaching printing press plates of cast metal containing about 80% Pb. Broaching operation consisted of cleaning inside of plate and at the same time giving a true and clean curface to the lugs. VSP (4c)

Cold Pressing and Drawing—the Metallurgical Aspect. C. H. DESCH. *Journal Royal Aeronautical Society,* Vol. 39, Nov. 1935, pages 1077-1080; discussion, page 1092. Cold pressing is applicable only to the more ductile metals, usually in the form of thin sheets. The metals must each possess sufficient ductility, absence of marked directional properties, uniform (usually small) grain size and, if possible, uniform texture throughout the thickness. Very fine grained materials behave, because of the general averaging of orientation differences, as if sensibly isotropic, while large grained materials may develop "orange peel" surfaces when deformed by pressing in a die. Fine grained materials, however represent some sacrifice in ductility, hence a compromise must be effected. The desired grain size and texture may be obtained by cold rolling followed by annealing or by normalizing only. Oxidation of the surface, either during annealing, normalizing or pickling must be avoided. Among the materials other than soft steel that can successfully be drawn and cold pressed are ductile stainless steels, Al and duralumin. FPP (4c)

Flow of Material in Cold Drawn Hollow Ware (Über Werkstoffwanderung bei der Herstellung kaltgezogener Hohlkörper aus ebenen Platten) H. MEYER AUF DER HEYDE. *Werkstatt und Betrieb,* Vol. 69, May 1936, page 132. After a short discussion of the different metals used in deep drawing, formulas for the flow of material are developed, results given in 7 tables. Practical examples show usefulness of formulas. ■ 4d. Machining ■

H. W. GRAHAM, SECTION EDITOR

Profiles for Propellers. GEORGE M. GILLEN. *Welding Journal,* N. Y., Vol. 15, June 1936, pages 9-10. Description of machine for automatically (machine) cutting propeller profile from forging. WB (4d)

Metal Turning for Instrument Makers. A. S. NEWMAN & R. S. CLAY. *Journal of Scientific Instruments,* Vol. 13, Apr. 1936, pages 109-114. A discussion of turning tools, tool holders and some of the kinks to be observed in getting good results. RAW (4d)

Tooling Chrysler Axle Shafts for Low-Cost Production. FRANK J. OLIVER. *Iron Age,* Vol. 138, July 9, 1936, pages 34-39. Describes the up-to-date installation of machining and heat treating equipment for machining rear axles at the plant of Chrysler Corporation. Material from which rear axle shafts are made is a special Chrysler Mo steel containing 0.60-0.65% C. Shaft reaches machine line rough forged to shape and in normalized condition. Gives details of machining operation and subsequent treatment. VSP (4d)

Rapid Grinding Technique for New and Damaged Carbide Tools Demonstrated. *Steel,* Vol. 98, June 1, 1936, pages 46, 48. Time for grinding carbide tools can be reduced greatly by shaping a crown about $\frac{1}{16}''$ high on grinding-wheel for roughing and semifinishing operations; maintenance of constant tool motion while grinding; use of an angle 4° greater than finished angle desired, when rough grinding, and finish grinding at desired angle, grinding on carbide tip only; and alternate grinding on carbide tip and steel shank when necessary to hog off large amounts of stock, as in case of chipped tools. Cemented-carbide Tools in Present American Shop Practice. R. D. PROSSER. *Metal Treatment,* Vol. 2, Summer 1936, pages 93, 106. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 118R/10. JCC (4d)

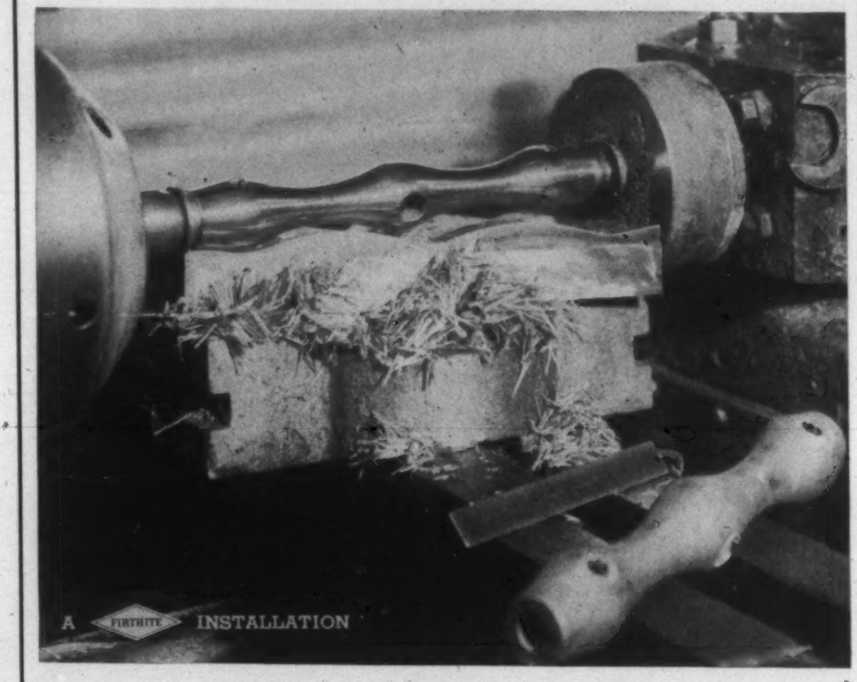
$2623 INDIRECT SAVINGS *with*

ONE FIRTHITE TOOL



Form turning a cast brass plumbing fixture, 10 inches in length, with a FIRTHITE tipped skiving tool, using a feed of 2½ inches per minute. The exceptional finish has reduced manufacturing costs on subsequent operations.

ILLUSTRATED here is a typical FIRTHITE installation that exemplifies FIRTHITE economy. Because of the superior finish . . . free from tool marks . . . made possible by FIRTHITE, grinding and polishing costs have been reduced from 8½ cents to 3¼ cents per piece. On the first 50,000 parts the user has saved $2,623.00—remarkable economy for a tool that costs only $181.00. Needless to say the tool still has tremendous life since it has been sharpened only twice.

It isn't always direct savings in machining time that make the largest FIRTHITE economies. Naturally, FIRTHITE cuts faster, and faster cutting means more output over a given time . . . a worthwhile saving in itself . . . but how about the many indirect FIRTHITE savings such as smoother finish, better accuracy, less distortion and cost reductions in subsequent operations?

5. HEAT TREATMENT

O. E. HARDER, SECTION EDITOR

Metallurgy of Transmission Gears. R. B. SCHENCK. *S. A. E. Journal*, Vol. 38, June 1936, pages 13-19. Gear failures are of 2 types, wear and breakage. Wear occurs as pitting of gear face due to fatigue under compressive stresses, and is progressive. Another form of wear is scoring where the surface flows due to improper design, poor contact, low surface hardness or excessive loading. Breakage of teeth is due to either low impact or fatigue, the former from improper heat treatment, the latter because of incorrect design, poor contact, low tooth strength, excessive overloading, or by notch effects, due to undercuts, roughness, or scratches at base of tooth. High C steels represent about 90% of total gear production according to recent survey of 20 passenger car manufacturers. Disagreement exists at present on relative merits of electric and O. H. steels. Low C steels are 6-8 grain size and high C of 4-6, 5-7 with 6-8 in general use. Large gears are forged in upsetter or under hammer, smaller gears sometimes machined from bar stock. Die design and macro-etch important for producing smooth flow in forging operation. Old style, manually-operated forge furnace is still being used. Annealing produces structures most suitable for machining and hardening, and is usually carried out in continuous, automatically regulated furnaces, permitting better control of cycle than in old batch type furnace. Low C steels are furnace or air cooled through lower critical from about 1750° F.; S A E 2515 requires slow cooling because of air-hardening tendency. Some plants air cool and others slow cool SAE 4615 and 4620. High C steels are slow cooled through lower critical from 1550° to 1750° F. Lamellar pearlite is aim of anneal. Mo steels do not form lamellar pearlite but have optimum structure of their own. More than small amounts of sorbite or spheroidal cementite give machining troubles. Fine grain must be cooled through Ar_1 more slowly than coarse grain to develop same amount of pearlite. Duplexed and banded structure are discussed and hardening of gears by pack carburizing reviewed. Low C gears are hardened directly from carburizing box at 1700° F. or 100° F. or more below hardening temperature, and where distortion is a factor gears are cooled in box and cyanide reheated to 1400°-1500° F. for hardening. Cyanide hardening procedure and equipment are detailed for continuous process. Drawing of gears ranges from 300°-500° F. in continuous salt baths, forced draft electric furnaces or gas fired continuous furnaces with automatic control. Low C gears have heavy case, soft core and high C, the opposite; the low C having case of .03"-.05", Rockwell C 55 to 62 and core of Rc 30-40. Rule used is "twice as much core as case" for which the aim is case depth of 1/6th tooth thickness at bottom of tooth. High C gears have case .001" to .010", Rc 48-58; core hardness Rc 45-55. Suggested rule for high C is .001" of cyanide case for each point of core hardness below Rc 55. Discussion is given of the relation of case to core for prevention of gear failure by wear, fatigue and impact. Present metallurgical practice at Buick plant is discussed in succeeding pages. The steel is O. H. product identical with SAE 3145 except for C range of .43-.48. Specifications cover chemistry, grain size, normality, banding, inclusions and macro-structure. Grain size 6-8 specified, duplex structure avoided, inclusions are rated according to a number scale. Macrostructure is examined with specimen of bar upset at 2350° F. to ¼ original length which parallels macro of forged gear. Present dispute as to merits of open and dense macro is mentioned as inconclusive. Forging is done on latest design forging machines and material annealed in under-fired continuous, automatically controlled furnaces with 4 separate zones to reduce annealing time and banding. Maximum amount of lamellar pearlite is aim and macro is compared in text with partially divorced and spheroidized structure. Cyanide hardening is practiced in conveyor system procedure including preheat, 4 cyanide pots, quench, wash and rinse to give average case of about .002". Drawing at 450° F. takes place in 2 hr. cycle in continuous furnace. Case ranges from .001" to .003" with Rc of 50-55, core hardness Rc 50-55 (light case has no effect on Rc). For high C gears an improved method is used for hardening in controlled atmosphere muffle furnace for which conditioned gas is used to produce case averaging .006". Case is of excellent quality, slightly hyper-eutectoid and spheroided excess cementite. After passing through muffle the gears are dropped into quenching tank under furnace. Drawing at 450° is next step. 2 Rc points of hardness increase are found for new process over cyanide hardened gears and distortion is less. WB (5)

The Importance of the Human Element in Heat Treating of Steel. L. WILLIAMSON. *Industrial Heating*, Vol. 3, Sept. 1936, pages 568-572. It is emphasized that in spite of all improvements and automatic devices for the operation of heat treating furnaces, skill, judgment and thought of the heat treater are still necessary and that the human factor must not be neglected in order to produce the best steel qualities. Ha (5)

Prevention of Oxidation and Decarburization of Steel. A. G. ROBIETTE. *Metal Treatment*, Vol. 2, Summer 1936, pages 77-84. Reviews the gas-metal reactions occuring between steel and annealing atmospheres during heat-treatment in controlled atmospheres. Excess water vapor, though reducing in action at the annealing temperature, will cause oxidation during cooling. Problems discussed include the production of water vapor by the water-gas reaction when combusted gases are used for bright annealing; the possibilities of descaling by means of a reducing atmosphere, decarburization, carburization; the influence of alloying elements on the behavior of special steels. Rich atmospheres made by partially burning coal gas are cheap and can now be used since methods for removing organic S have been developed. Typical furnaces are reviewed and some industrial applications outlined. JCC (5)

Influence of Isothermic Treatment on Mechanical Properties of Chromium-Nickel Steels (Contribution à l'étude de l'influence du traitement isothérmic sur les propriétés mécaniques des aciers chrome-nickel) J. E. KONTOROVITCH. *Revue de Métallurgie*, Vol. 33, July 1936, pages 460-465. 4 steels with 0.14-0.39% C, 0.8-1.8 Cr, 2.2-3.6 Ni were investigated. Properties obtained by isothermic transformation and usual quenching and drawing were practically the same. JDG (5)

Heat Treatment of Cast Iron. A. A. TIMMINS. *Foundry Trade Journal*, Vol. 54, May 28, 1936, pages 421-423. See *Metals & Alloys*, Vol. 7, June 1936, page MA 289L/1. AIK (5)

5a. Annealing

Stress-Relief Annealing High-Strength Monel Metal Plate. PETER R. KOSTING. *Preprint meeting American Society for Testing Material,* June 1936, 9 pages. The effect of temperature of annealing and time at temperature upon the physical properties of 4 heats of high-strength Monel metal plate, ½″ thick, was studied. Particular attention was paid to yield strength, 0.00% set, extensometers of 0.0002″ and 0.00002″ sensitivity being used. In the range 550° to 600° C. the maximum increase in yield strength, 0.00% set, is obtained no matter whether the plate were slightly cold rolled or hot rolled but finished at a low temperature during manufacture. Annealing first increases and then decreases the yield strength at higher per cent sets. The temperature at which maximum values are obtained is governed by the amount of cold working to which the metal was subjected. The tensile strength reached at 450° C. is slightly higher than that at 550° or 600° C. Yield strengths, 0.2 and 0.05% set, pass through slow maxima at 450° C. in 2 to 3 hrs. and sharper maxima at 550° C. At 600° C. yield strength of 0.05% set is unaffected but of 0.2% set is lowered. The extent of increase of yield strength 0.00% set, is dependent upon the temperature and time at temperature. An increase of 11,000 lbs./in.^{2} was noted after 3 to 4 hrs. at 450° C., but the maximum increase noted of 15,000 lbs./in.^{2} was reached in about 1 hr. at 550° C. and in less than 1 hr. at 600° C. If held longer at 550° C. there is no falling off of yield strength but at 600° C. there is a very slight falling off. The yield strength, 0.00% set, is sensitive to the presence of internal stresses. When the maximum increase in this yield strength was obtained it was judged that the internal stresses had been removed, if not completely, then sufficiently for practical purposes. Heating to 575° C. and holding for 3 hrs. and furnace cooling is a suitable treatment for stress-relief annealing this high-strength monel metal plate.
VVK (5a)

5b. Hardening, Quenching & Drawing

Change of Hardness in Quenched Carbon Steels by Tempering. RIMPEI KIKUCHI. *Kinzoku no Kenkyu,* Vol. 13, Aug. 1936, pages 333, 341. In Japanese. Author considered the mechanism of tempering of quenched C steels as follows: On tempering quenched steel its hardness increases at first and then decreases. This change of property takes place by the following 3 processes; (1) the transformation of α martensite into β martensite (hardening), (2) the separation of cementite from β martensite (softening), (3) the change of residual austenite into martensite (hardening). These processes take place very slowly when the temperature is not sufficiently high, since the diffusion velocity in solid solution is very small. The author proved his theory by measuring hardness of quenched C steel (0.85% C), tempered for a prolonged period, and the following results were obtained; (1) on tempering up to 95°, α martensite changes into β martensite, (2) by tempering above 100° the decomposition of β martensite takes place, and (3) between 100° and 150° the change of residual austenite into martensite is completed.
KT (5b)

Tempering High Speed Steels. I. Z. YASNOGORODSKI. *Kachestvennaia Stal,* Vol. 4, No. 4, 1936, pages 29-36. In Russian. Steels containing 0.72 C, 4.20 Cr, 17.20 W, 1.08 V; 0.69 C, 4.35 Cr, 11.25 W, 2.04 V; 0.62 C, 2.97 Cr, 17.70 W, 0.72 V, 6.50 Co were quenched between 1200° and 1300° C. and tempered for different length of time between 200° and 650° C. Properties produced were studied for hardness at room and elevated temperatures, magnetic characteristics (apparatus for testing is described) and cutting properties. Continuous and intermittent tempering was tried. Optimum drawing temperatures for these steels are located between 500° and 550° C. Higher drawing temperature under identical conditions leads to faster martensite decomposition lowering hardness and stability of the metal. Intermittent tempering leads to more rapid austenite decomposition which is practically complete after 3-5 treatments. Hardness of high speed steel and its cutting qualities increase with increased amount of decomposed austenite. This recommends intermittent tempering. (5b)

Use of Chromium-Manganese-Molybdenum Steel for Castings. Z. I. KOPELMAN & T. V. SERGIEVSKAIA. *Kachestvennaia Stal,* Vol. 4, No. 4, 1936, pages 50-53. In Russian. By normalizing and oil quenching castings made of steel containing 0.32-0.40 C, 0.25-0.50 Si, 1.40-1.60 Mn, 0.6-0.8 Cr, 0.50 max. Ni, 0.35-0.45% Mo it was possible to produce in medium size casting the following physical properties: 63 kg./mm.^{2} elastic limit, 78 kg./mm.^{2} tensile strength, 18% elongation and 7.7 kg.m./cm.^{2} impact strength. Castings did not warp or crack. A number of heats were made and cast with satisfactory results after heat treatment. Detailed information regarding heat treating practice is given. (5b)

Hardening of High-Speed Steel. MASUHIRO SUZUKI & SIGEO OWAKU. *Kinzoku no Kenkyu,* Vol. 13, June 1936, pages 223-260. In Japanese. Authors investigated the cutting efficiency of ordinary high-speed steel, which contains about 18% W, 4% Cr and 0.8% C, and the so-called super-high-speed steel which contains Co besides the above constituents. The cutting efficiency of high-speed steel tools depends upon the heat treatment as well as upon the constituents. The heat treatment studied by the authors includes the hardening temperature, the length of time at that temperature, the properties of cooling liquids, the tempering temperature, the time of tempering and the structure of steels. The result is as follows: the high-Co high-speed steel which contains more than 10% Co is the best; the quenching temperature is 1300° C; the time of heating is 2 minutes for a specimen of 10 x 10 x 50 mm.; severe quenching is not recommended; the tempering temperature is 600° and the time 20-60 minutes. The high-speed tools obtained in this way have a hardness of Rockwell C 68 and can easily cut, plane or drill water-toughened high Mn steel. KT (5b)

Historical Data Relating to Hot-galvanizing Practice for Wire. J. L. SCHUELER. *Wire & Wire Products,* Vol. 11, Aug. 1936, pages 383-385, 403. A history of the hot-galvanizing process is given and the progress and improvements in the latter process during the last 15 years, in particular the galvannealing process, the Crapo process, and the flame sealed process, are described. Ha (5b)

MISCO "Centricast" Furnace Conveyor Rolls
(Centrifugally Cast)

NO MECHANICAL JOINTS are used in the manufacture of Misco "Centricast" Furnace Conveyor Rolls. The end castings are *flash welded* to the centrifugally cast tube. This construction was *originated* by Misco, and more than 300 of these rolls are now in use at temperatures up to 2050°F. Your inquiries are invited. Michigan Steel Casting Company, 1981 Guoin Street, Detroit, Michigan.

Part of a recent shipment of 173 Misco *flash welded* "Centricast" Furnace Conveyor Rolls.

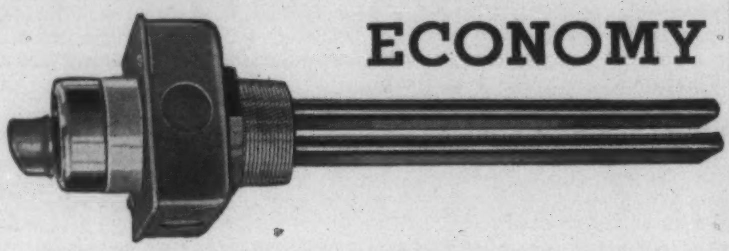
Heat and Corrosion Resistant Alloys

KANTHAL'S
"DOUBLE HEADER"
ECONOMY



MORE compact units are possible because less material is needed when Kanthal is used. Required heat is attained with less bulk because of Kanthal's higher electrical resistivity.

Kanthal D will produce more units per pound because its specific gravity is 15% lower than that of nickel chromium which is more commonly used. Its electrical resistance is 24% higher.

Quenching, Drawing or Normalizing
. . . it's all the same to a SPENCER TURBO

The furnace illustrated is a modern, pusher-type, double-chamber unit used for quenching, drawing and normalizing. The air supply is a standard Spencer Single-Stage Turbo-Compressor.

Notice how the Turbo is mounted on the equipment. This is becoming the usual practice because the Spencer Turbo is so quiet, so compact and so free from vibration that it is practical to locate it at the point of greatest convenience and economy.

Spencer Turbos, although a recognized standard for all types of oil- and gas-fired steel-treating equipment for a quarter of a century, still differ in the essential points from any other equipment.

They are unusually simple in construction and design. Light weight impellers with wide clearances, operate within a reinforced, rust-resistant steel casing. There are only two bearings and no other moving contacts.

Delivery of air at predetermined pressure is automatic up to the full capacity of the Turbo. When no air is required, the Turbo idles and uses only a minimum of power.

Thermal Treatment of Steel with a Minimum Warpage. V. V. CHERNISHEV. *Kachestvennaia Stal,* Vol 4, No. 3, 1936, pages 30-34. In Russian. 3 steels were investigated having a composition of: 0.28% C, 0.95 Cr, 3.00 Ni, 0.31 Si, 0.36 Mn; 0.36 C, 1.55 Cr, 3.43 Ni, 0.38 Si, 0.65 Mn; 0.34 C, 1.58 Cr, 4.30 Ni, 0.24 Si, 0.52 Mn. Determinations were conducted on round test bar specimens, warpage being obtained as displacement from the true axis of these specimens. Interrupted quenching gave the least warpage. The best results were obtained by heating steels to their austenitic range for 20 minutes at temperatures corresponding to great stability of supercooled austenite (525° C. for the first steel and 500° C. for two remaining) and then heating them for 1 hour at 325° C. for the first and 300° C. for the remaining two. Producing the desired physical properties, this treatment practically eliminates warping. (5b)

■ 5c. Aging ■

Cyanidation of Cutting Tools. V. YA. DUBOVOI. *Kachestvennaia Stal,* Vol. 4, No. 6, 1936, pages 46-50. In Russian. Shop experiments showed that useful life of cyanided drills, threading milling cutters, broaches and shaped cutters was about 3 times as high as of those which were not so treated. Shaper tools were, however, inferior to the untreated. All tools were made of standard high speed steel and were cyanided after final heat treating and grinding. Cyaniding was conducted at 565°-575° C. in 96-98% NaCN. No definite dimensional changes were observed after cyaniding, but a further study is necessary. Time of cyaniding depends on the mass of the samples, and on the desired depth of case. Cooling can be conducted in air. Treating for 10-20 minutes seems to be the best for medium size drills. (5c)

Age-Hardening Mechanism in Ag-Al Alloys. MASAHIDE KOSAKI. *Kinzoku no Kenkyu,* Vol. 13, Aug. 1936, pages 342-348. In Japanese. In order to investigate the mechanism of age-hardening in Ag-Al alloy, a study was made with an alloy containing 40% Ag quenched from 550° C. in water, after being heated at that temperature for 30 minutes, followed by aging at room temperature for 20 days and tempering for 6 hours at 60°, 100°, 150°, etc., respectively, and then cooling slowly in the furnace. The variation in lattice constant, density and hardness of the specimen due to the above heat-treatments was measured; dilatation and electric resistance curves of the quenched specimen during a slow heating were also taken. The result of measurements led to the following conclusion; in the course of aging the hardness attains a maximum value at the instant prior to the separation of crystallites, while it decreases after their separation. This result is in agreement with the so-called solid solution theory on age-hardening phenomenon. KT (5c)

■ 5e. Carburizing ■

Cementation of Steel by Gases Produced by Pyrolysis of Oil Products. N. A. MINKEVICH, S. K. IL'INSKI & V. N. PROSVIRIN. *Kachestvennaia Stal,* Vol. 4, No. 2, 1936, pages 31-43. In Russian. Comprehensive investigation of carburizing produced with gases obtained by cracking kerosene and some oils. The liquid was vaporized and then passed through a tube furnace heated to 700°-850° C. Gases so produced were used for laboratory and commercial scale experiments. For the same depth of carburization the use of these gases produces the results 2-2.5 times cheaper than box carburizing with solid compound. (5e)

Carburizing Steel With Charcoal Generator Gases. M. G. PYATIGORSKI. *Kachestvennaia Stal,* Vol. 4, No. 4, 1936, pages 43-49. In Russian. Laboratory gas generator was developed in which gases were obtained by combined action of air stream on charcoal and kerosene which was introduced in the apparatus drop by drop. The device is described. Carburization with gases so produced yielded entirely satisfactory results. (5e)

Steels in Truck Production. A. G. VLADIMIROV. *Kachestvennaia Stal,* Vol. 4, No. 5, 1936, pages 22-24. In Russian. In order to reduce Ni consumption Cr-Mn-Mo steels were investigated as material for truck gears. With steels containing 0.2% C, 0.9 Mn, 1.0 Cr and 0.3 Mo after cementation at 900° C., quenchings at 850° and 800° C. in oil and drawing at 200° C. it was possible to obtain 70-72 kg./mm.^{2} yield point, 102-106 kg./mm.^{2} tensile strength, 17-19% elongation, 44% reduction in area and 10 kg. m./cm.^{2} impact strength. Structure of carburized layer is the same as in Cr-Ni steels. (5e)

Carburization of Basic Electric Steel from Masa Magnetic Sand. TOYOZO ISHIGAKI. *Suiyokwai-Shi,* Vol. 9, July 1936, pages 57-71. The author carburized the basic electric steel from Masa magnetic sand in a mixture consisting of charcoal powder and $BaCO_3$, and after confirming the existence of a close relation between the occurrence of the abnormal structure of the carburized steel and the O content in the uncarburized steel, he carburized electrolytic Fe in the above mentioned carburizing mixture. It was found that the abnormal structure begins to appear in the pure Fe when its O content exceeds about 0.052%. He concludes that the abnormal structure never arises from carburizing because the O content of the basic electric furnace steel from the Masa magnetic sand is always far below the limit of the occurrence of the abnormal structure, namely below 0.015%. HN (5e)

New Method for Surface Hardening Austenitic Steels (Les nouveaux procédés de durcissement superficiel des aciers austenitiques) E. VALENTA & V. KOSELEV. *Revue de Métallurgie,* Vol. 33, July 1936, pages 466-472. In order that a Hadfield steel may remain austenitic its C content should be sufficiently high. When Mn is kept the same but C is reduced martensite is formed. C reduction on the surface can be achieved by decarburization in a slightly oxidizing atmosphere. The depth of martensitic layer so produced is inversely proportional to Mn content. The best composition is 7% Mn and 0.7% C. Decarburization can be efficiently conducted in N_2 containing about 2% O_2 at 1000°-1080° C. Lower temperatures than these increase the reaction time; at higher temperatures coarse crystallization begins. Average decarburization under these conditions is 0.067 mm./hr. In the very outside layers C removal goes too far so that martensitic case begins slightly farther in. JDG (5e)

THIS MODERN MACHINE DRIES AIR AND GASES

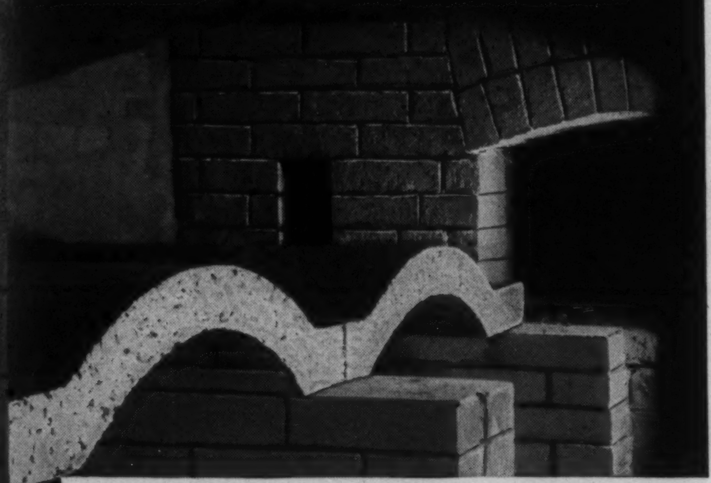
J-M FIRECRETE

for casting shapes yourself

QUICKLY . . . at low cost



● Use this hydraulic-setting J-M Refractory Cement for pouring door linings, flues and pipes; for dampers and special shapes. Handled like ordinary concrete, Firecrete saves time, labor and expense. And it's exceptionally strong, highly spall-resistant, with practically no drying or fire shrinkage. For details on Firecrete and other J-M Refractory Cements, write to Johns-Manville, 22 E. 40th Street, New York City.

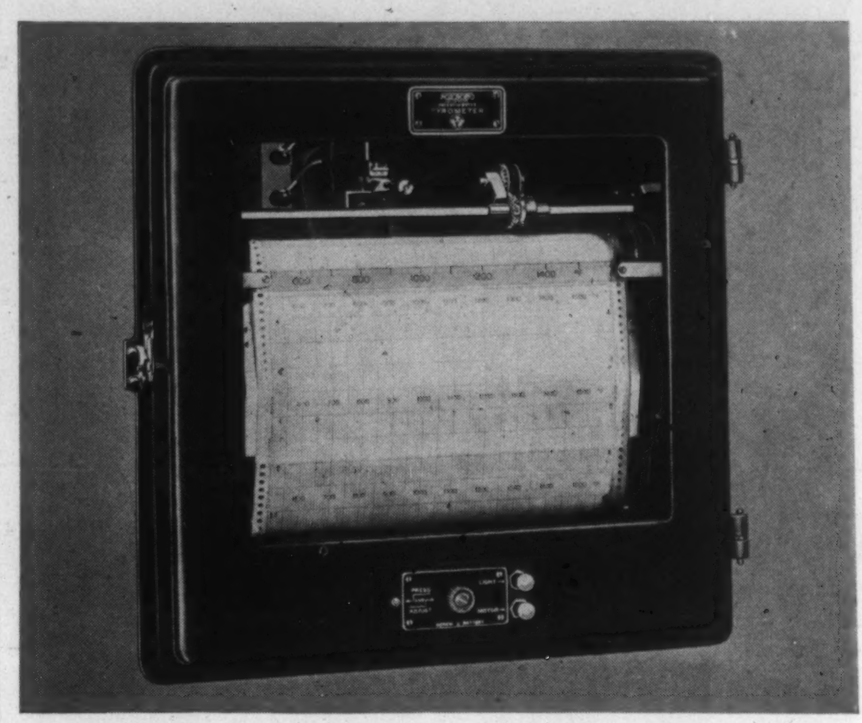
5 FEATURES THAT MEAN SAVINGS FOR YOU



with a FOXBORO Pyrometer

SENSITIVITY
ACCURACY
SIMPLICITY
QUICK RESPONSE
LONG LIFE

Dependability in the extreme sense of the word is what you get in every Foxboro Potentiometer Pyrometer. Every record is a true picture of temperature at the exact time it existed. You get rapid response to thermocouple temperature changes.

The enduring accuracy and sensitivity is assured by a movement that is both mechanically and electrically simple. You get a lasting accuracy of ¼ of 1% of scale range and a clear 12-inch wide chart record. A complete line is yours, from which to choose the range and type of record ideal for your specific service.

Bulletin 190-1 describes this line in detail. Write for a copy.

—THIS IS 1936!

A DIPLOMA represents a definite course of training, just as a calendar represents a definite period of time, but both lose value when they are out of date. The challenge of 1936 is — modernization of training!

Today, in greater number than ever before, college graduates are enrolling for International Correspondence Schools Courses in order to bring their training up to date. They realize that old training is not adequate to meet the problems of a new age in business. Other ambitious men, without the benefit of diplomas, see in spare-time study of I. C. S. Courses the shortest road to success in their chosen careers.

Mastering an I. C. S. Course is no easy job. (Getting ahead in this competitive world is not easy either!) But to men who have courage and perseverance, I. C. S. stands out as a citadel of opportunity. This coupon is the key to complete information. Take the first step toward modernization — and more money! Take it right now. Remember, your competitors are taking it.

Modernize

6. FURNACES, REFRACTORIES AND FUELS

M. H. MAWHINNEY, SECTION EDITOR

Notes on Copper Refinery Furnace Firing and Refractories. H. C. ROBSON. *Bulletin Institution Mining & Metallurgy,* No. 373, Oct. 1935, 8 pages; No. 374, Nov. 1935, pages 1-15; No. 376, Jan. 1936, pages 25-29. Pulverized coal firing has the following advantages over grate firing: (1) Fuel costs are reduced 55%, (2) the sequence of the refining cycle is smoother (no interruptions for declinkering, etc.), (3) it is at all times under full control (as to temperature, oxidizing conditions, etc.), (4) during periods of inactivity coal fired can be cut instantaneously to the minimum, (5) the choice of coal is wide and even inferior grades can be used. A new burner is described. Repair costs were reduced 75% over 3 yrs. by replacement of ordinary refractories by large silica blocks, rubbed together to give a perfect joint, fettled after each charge with white quartz ground to —¼″ and mixed with 10% H_2O. A detachable sectionalized roof of superior design is shown; 10 advantages are listed. AHE (6)

Automatic Handling of Mill Length Shapes During Heat Treatment. E. J. JANITSKY. *Metal Progress,* Vol. 30, Oct. 1936, pages 55-58. Describes equipment for handling automatically mill lengths of a large variety of shapes and sizes from the heat treat furnace. The automatic handling drains the material from the quench and charges it in the draw furnace. WLC (6)

Controlled Furnace Atmospheres. E. O. MATTOCKS. *Metal Progress;* Vol. 30, Oct. 1936, pages 27-34, 46. Review of use and application of controlled atmospheres in heat treatment. 12 references. WLC (6)

Automatic Machines for Carburizing. J. B. NEALEY. *Metals & Alloys,* Vol. 7, Oct. 1936, pages 250-252. Description of continuous type pot carburizing furnaces and their hardening and tempering accessories. WLC (6)

Hardening Razor Blade Steel by a New Process. ALBERT R. STARGARDTER. *Metals & Alloys,* Vol. 7, Oct. 1, 1936, pages 253-256. Describes briefly use of inductive heating for treating razor blade steel in strip. The novel feature is a control arrangement not described in detail which controls the quality of the heated product of the furnace. The hardened strip passes through a magnetic test and the results of this magnetic test automatically adjust the furnace conditions to produce the desired structure in the steel. The magnetic properties have been associated with the structure of fine evenly distributed carbides which is desired. Micrographs show the structures of good and inferior hardening. WLC (6)

Refractories, Recent Types, Uses and Unit Costs. *Metal Progress,* Vol. 30, Oct. 1936, pages 59-63, 72. Review of refractory types and their application, properties and costs. WLC (6)

New Ideas in Furnaces. *Metal Progress,* Vol. 30, Oct. 1936, pages 64, 65, 69, 70. Review and discussion of 5 articles on furnace designs. WLC (6)

Insulation of Open-hearth Furnaces. E. ORCHARD. *Iron & Steel of Canada,* Vol. 19, Aug. 1936, pages 12-13. Method used by the Algoma Steel Corp. is described for furnace and checkers. Ha (6)

Vertical Furnaces for Hardening, for Tempering. F. E. HARRIS. *Metal Progress,* Vol. 30, Aug. 1936, pages 52-56. Describes design and operation of vertical furnaces for the heat treatment of automotive parts. WLC (6)

Pouring Pit Refractories and Their Effect on Alloy Steel Quality. E. E. CALLINAN. *Industrial Heating,* Vol. 3, June 1936, pages 383-386; Sept. 1936, pages 579-582; *Iron & Steel of Canada,* Vol. 19, Aug. 1936, pages 8-10. The effect which pouring refractories may have on the quality of alloy steels and the properties which they must possess to minimize chances of ruining heats of steel are discussed. Correct physical and chemical properties to resist molten slag and metal attack and high refractoriness are of prime importance, in particular in the ladle. Ladle bricks are at present usually made of siliceous clays, a typical composition being 66% SiO_2, 25% Al_2O_3, 4.5% Fe and Ti oxides, 0.4% CaO, remainder mainly Mg, Na and K oxides; max. firing temperature 2200° F. Materials used for nozzles, sleeves, hot tops, plugs and their shapes are described. Cooperation between steel producer and ceramic engineer for further improvement is advocated. Ha (6)

Swedish Steel Made in Electric Furnace. EINAR OEHMAN. *Metal Progress,* Vol. 30, Sept. 1936, pages 72-73. Statistics and history of electric furnace production of steel in Sweden are accompanied by reference to a new 2-frequency type of melting furnace being developed. In this furnace a high frequency coil induces the melting current in the charge and a low frequency coil produces vigorous stirring action with rapid refining action by emulsification of the slag with the steel. Both currents may be regulated at will. WLC (6)

Combustion Chamber Design for Industrial Furnaces. M. H. MAWHINNEY. *Industrial Heating,* Vol. 3, Sept. 1936, pages 563-566, 596. The points to be observed in the design of efficient combustion chambers with respect to temperature, dimensions and rate of heat liberation are discussed in detail. Ha (6)

Colloidal Fuel. A. B. MANNING & R. A. ACTON TAYLOR. *Industrial Chemist,* Vol. 12, Mar. 1936, pages 111-112. An abstract of a paper read before the institution of Chemical Engineers on Feb. 21, 1935. RAW (6)

THE HABIT OF LEADERSHIP!

FOR nearly three-quarters of a century—and that period the most progressive in the world's history—we have constantly anticipated the needs of industry.

Today, with a sense of justifiable pride, we look back over the long years of established leadership—a leadership that has become a habit and is so recognized by those who use our products.

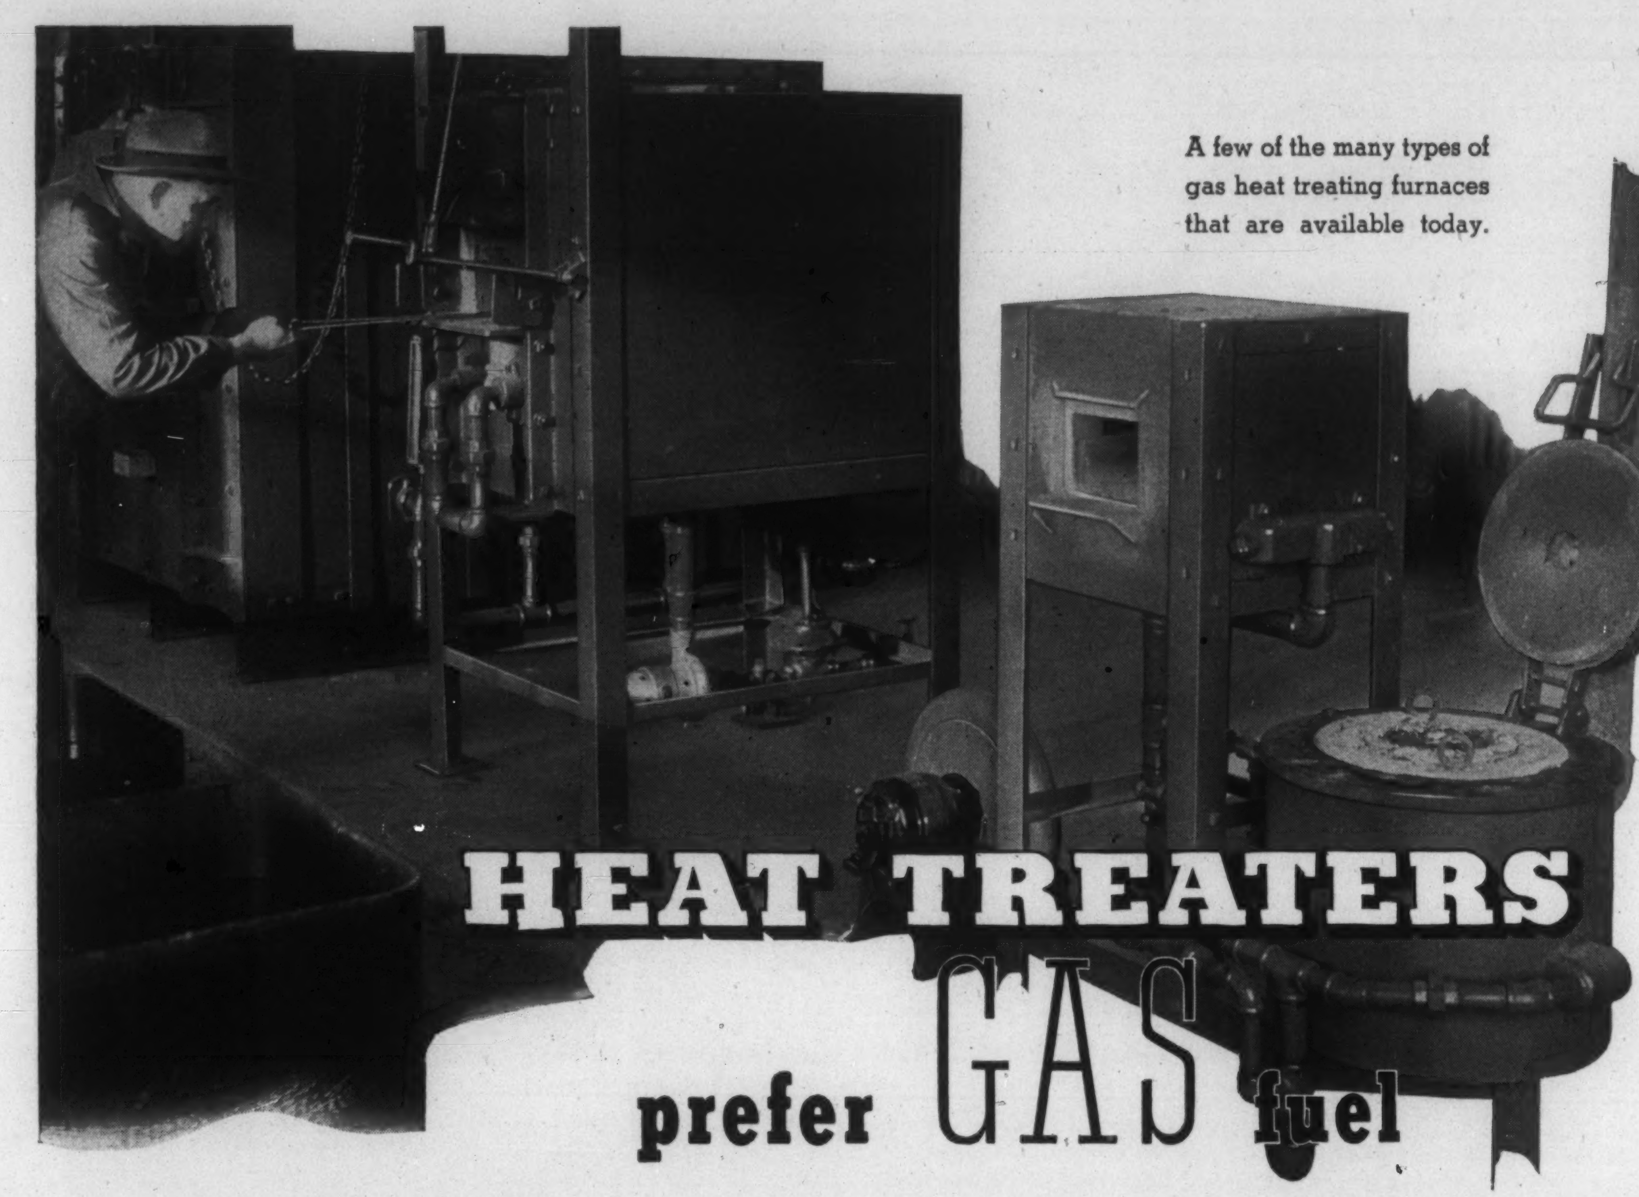
But we are not resting on our laurels—we know the necessity and the cost of forging ahead. Tomorrow we hope to dim the luster of our own achievements of today.

We appreciate the fine cooperation of our customers, so essential to our consistent success, and whether it be fire-brick or P. B. Sillimanite super refractories, carrying the Chas. Taylor trade-mark, available to the glass and metal industries in feeder parts, special shapes and plastics, we will continue to make your problems our problems, and endeavor to give you the satisfaction we have accustomed you to expect.

SUPER REFRACTORIES

P. B. Sillimanite

THE CHAS. TAYLOR SONS CO.
CINCINNATI



A few of the many types of gas heat treating furnaces that are available today.

HEAT TREATERS prefer GAS fuel

In small heat treating shops and in large industrial plants with heat treating departments, Gas has long been the preferred fuel. This is significant, because the heat treater knows that his reputation and future depend upon the quality of his work. And both he and the plant operators have found Gas to be more dependable and more satisfactory. They have found that Gas is more flexible, more easily controlled, more accurately controlled, more convenient, cleaner, and more economical.

Today, the preference for Gas in heat treating shops, is increasingly pronounced. Modern and more efficient applications of Gas—for forging, carburizing, core-baking and many other processes—have been made possible by important research developments. And this combination of dependable gas fuel and up-to-date equipment is improving quality, reducing the number of rejections, increasing production and lowering over-all costs in heat treating shops everywhere.

THE TREND TODAY IS TO GAS
THE MODERN INDUSTRIAL FUEL

You, too, will want to take advantage of the new economies and new efficiencies offered by gas fuel today. Call your gas company industrial engineer for detailed information regarding the application of Gas to your special heat treating operations.

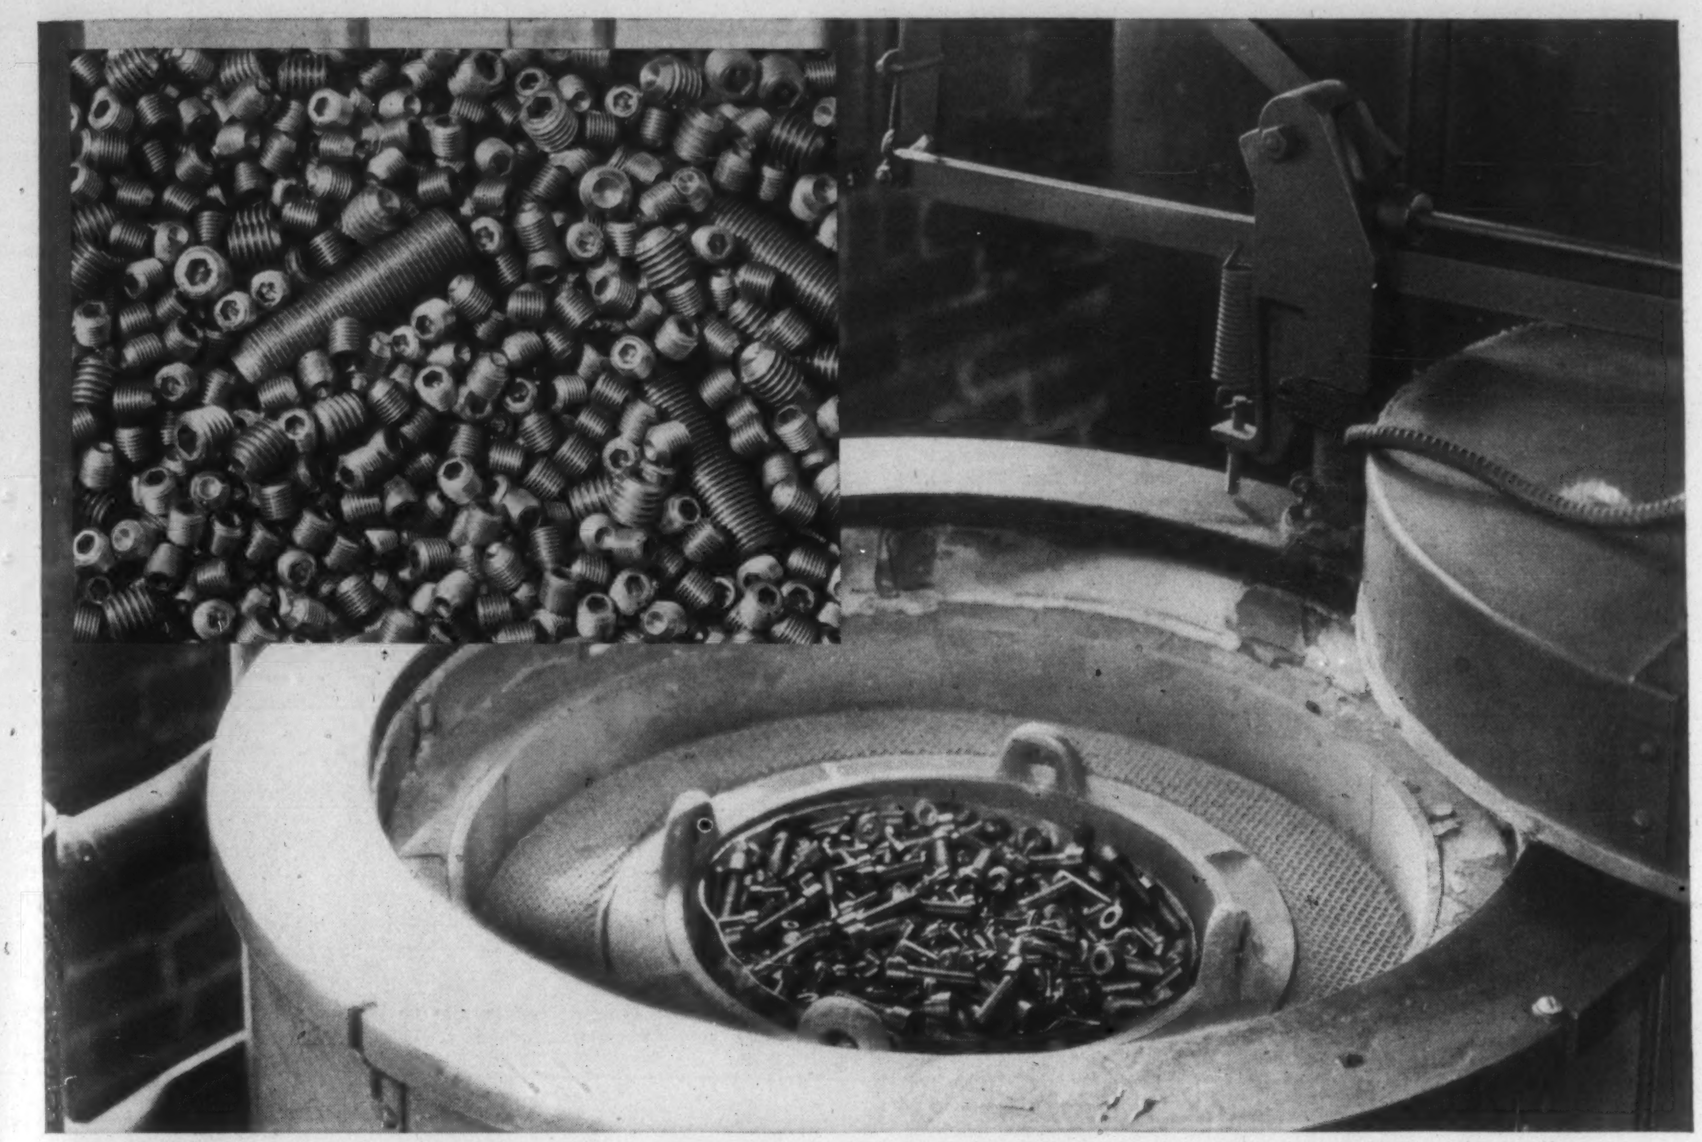
INVESTIGATE THE ADVANTAGES OF GAS FOR:

Hardening
Carburizing
Annealing
Drawing
Tempering
Normalizing
Blueing
Nitriding
Forging
Galvanizing
Core Baking
Spheroidizing
Malleablizing

And many other processes.

AMERICAN GAS ASSOCIATION

INDUSTRIAL GAS SECTION: 420 LEXINGTON AVENUE, NEW YORK CITY



Uniformity . . . PROTECTED BY HOMO TEMPERING

Because the physical qualities of set-screws must be rather exactly balanced, precise tempering is vital. Enough draw must be conceded to prevent breakage, yet enough strength retained to foil the husky who slips a pipe over his set-wrench handle.

The Mac-it Parts Company finds that Homo forced-convection tempering gives the uniform, controlled heat that solves this tempering problem. They pre-determine both temperature and time of draw, and set the Recording Controller so that tempering is automatically done just as they want it. Skill and experience are concentrated on deciding what temperatures are needed—rather than on watching the furnace to make it hold them. And the Homo record of each batch helps the heat-treater apply his experience to best advantage on succeeding batches. As a result, tempering is a solved problem in this plant. Other plants can enjoy the same advantages; details on request.

7. JOINING

7b. Welding & Cutting

E. V. DAVID, SECTION EDITOR

The Effect of Welding on Design. T. McLean Jasper. *Welding Journal,* N. Y., Vol. 15, July 1936, pages 2-8. One advantage of welding in pressure vessel field is weight reduction of 25% with same safety as previous lap-riveted joints. Seamless, butt joints by welding are of advantage in many fields. In the past, quality of welding was lower than that of the steel, but now welding has surpassed steel quality and poor welding is often caused by poor steel. Advance in welding is due to production of better quality steels. Higher or equal physical properties for the weld over those of the plate are preferred. Tensile tests on welded joints are shown in curves and illustrations, indicating 16% higher tensile for weld than plate. A graph is given of pull test results on specimens cut parallel to weld, and including it showing gradual rise in tensile strength from 2⅝″ thick parent metal to the weld and steeper rise of proportional limit for the same sections, peak values occurring in the weld. Excellent cold bend ductility shown in photos for all weld metal and the joint section. Charpy impact is said to be 25 for plate and 30 for weld and between these ratios for material between parent and weld metal. Welded plate stressed parallel to weld requires high weld ductility to prevent fracture in the weld since during the stress the weld carries the same load as the plate material. Stress relief by peening or by heating to 1150° F. is required for thick sections. Pressure vessel curves are given of yield points of cylinder wall, unreinforced manholes, old type dished heads and these are compared with similar results on weld design of reinforced manhole and elliptical head; conclusion therefore is that 40% less weight and welded design would give same strength. Use of lime wash is recommended for non-destructive pressure test to reveal areas of local stress. WB (7b)

Welding Research at the Royal Naval College, Greenwich. *Welder,* Vol. 8. May 1936, pages 936-940, 953. Review of reports on physical tests, load carrying ability of welded joints of various types used in ship building. Results of tests indicated little difference between single and double V welds and high tensile strength of welds is not necessarily associated with brittleness. Oxyacetylene welds gave uniformly less satisfactory results and electric welds give properties closely approaching those of the plate. Results of fatigue tests on welds made with Haigh's push and pull machine show fatigue limits of 5½-6 tons/in.^{2} consistently obtained even when slag inclusions and gas cavities are present provided there is no lack of fusion at weld-plate surface. Criticism of the Wöhler type fatigue tests using a weld sample smoothly finished all over is made and figure of 12-14 tons/in.^{2} considered too high for conditions in practice where roughness, slots or keyways act as stress raisers. Discussion of tests on upper and lower yield points. Haigh's definition of lower yield point is recommended for general use in tensile testing with the consequence of use of yield figures for design rather than ultimate. Lower yield point is consistent, easily determined and closely related to loads at which plastic behavior becomes dominant. Prediction is made that lower yield point and fatigue limit will be most important design basis in the future. New theory of fatigue cracking is that "it is not directly due to the plastic action that produces yield in ductile metals through the agency of the mechanism revealed by "slip bands," but to a recrystallization associated with reduction of volume—causing tensile stresses acting in all directions with more or less equal intensity. Such combinations of tensions acting in all directions are described as "negative fluid pressures" or as "triple tensile stresses." Analogy of theory with recrystallization in creep is pointed out. The formation of the initial fatigue crack is attributed not to plastic yielding in the metal, but rather to the fact that it does not yield easily enough to save the metal in the cone from excessive fluid tension." WB (7b)

Combining Castings and Weldings. T. S. Quinn & John Howe Hall. *Industry & Welding, Executives' Quarterly,* Second Quarter, 1936, pages 51-54. Foundry shops are being called upon to supply increasing demand for castings to be assembled by welding into finished structure combining cast and rolled sections. For complicated structures casting usually is cheaper process as it involves no expensive cutting of parts as for welding. Weakest parts of castings and welds are apt to occur in similar places such as change in cross-section. Cast steel of .20-.30 C considered as easily welded as rolled structural steel. Several examples of cast-weld assembly are illustrated. WB (7b)

The Wist Process of Electric Welding (La soudure électrique Wist) L. Kirste. *L'Aéronautique,* Vol. 18, July 1936, pages 149-150. In the Wist process an arc is struck between concentric C electrodes between which alcohol vapor is blown. A long-pointed flame, having a very high temperature, is produced, and it is claimed that with this welding can be carried out 50 to 100 times more rapidly than with an oxy-acetylene blowpipe. JCC (7b)

The Electric Arc Welding Process. IV, V, VI. T. A. Long. *Welder,* Vol. 8, Apr. 1936, pages 900-903; May 1936, pages 932-935; June 1936, pages 964-967. Advantages of a.c. over d.c. are cited; absence of arc blow with a.c. is important for welding of corners. Arc blow is not serious between 50-260 amps. but for 22-20 gage sheet with 20 amps. arc blow is serious and a.c. is used with great advantage. Study of a.c. equipment is made and indicates constant current advantage in welding and advantage to electric power industry because of lack of large surge on short current. Power factor and correction methods are analyzed and calculations for size of welding transformer plants shown. Part V. Electrical considerations of multi-operator a.c. welding plants are detailed and operating characteristics discussed. Part VI. Low ducility and impact of bare wire welds are compared with covered rod. Output rating of a.c. and d.c. is discussed in detail; guaranteed continued output is best basis for purchase of machines. For a.c. machines a min. striking voltage of 90 should be available for wide flexibility of operation and better welding characteristics. Electrical efficiency is reviewed and it is shown that idle d.c. equipment consumes approx. 7 times more energy than idle a.c. Cooling is taken care of in design of d.c. rotating equipment. A.c. equipment may be either oil- or air-cooled. WB (7b)

Some Welding Jigs and Fixtures. J. Ashworth. *Welder,* Vol. 8, June 1936, pages 977-980. Requirements for welding jigs are: (1) accuracy to enable the operator to tack weld without measuring, (2) it must make the work accessible so operator can easily reach point to be welded, (3) it must be rigid to some extent depending upon the class of work to be welded, and (4) welder should be able to do his work with little or no change in position. Contraction during cooling of weld controls the amount of rigidity in jig and this depends on type and size of materials welded. Several examples of large and small jigs are shown. WB (7b)

Electric Arc Welding from the Scientific Viewpoint. J. H. Andrew. *Welder,* Vol. 8, June 1936, page 968. Welding process is regarded as that of making a small chill casting between two sections of metal in such a way that prior to solidification of the bulk of the liquid metal, a complete union between the small casting and the parent metal is brought about by diffusion. Too high a liquid metal temperature coarsens weld metal and overheats adjacent parent metal; if it is too low, no diffusion occurs. Electrodes of different composition have different melting temperatures and require adjustment of welding current. Normalization temperature is just attained in lower bead by succeeding bead and ideal conditions are considered to be obtained for a high crested weld, the crest of which is then ground or machined off. Low annealing temperature of 650° C. for stress relief is considered to be injurious to structure if temperature can rise to 680° C. due to grain boundary migration of carbides. Normalizing at 630° C. max. is considered better practice. Study of slags resulting from covered electrodes is recommended for determining oxidizing effects on rod alloys and physical properties of liquid and cold slag. WB (7b)

The Importance of Welding in Paint Plant. C. W. Brett. *Paint Technology,* Vol. 1, July 1936, pages 263-264. The advantages of welding in replacing parts over riveting are pointed out. One of the newest welding processes known as the British low-temperature method enables the heat developed to be localized so strictly that the expensive and time wasting preliminary of pre-heating is entirely obviated. This enables the repairing to be carried out without dismantling. WHB (7b)

Effects of Generator Characteristics on Welding Costs. John H. Blankenbuehler. *Canadian Machinery,* Vol. 47, May 1936, pages 49-52. See *Metals & Alloys,* Vol. 7, Sept. 1936, page MA 452R/2. WB (7b)

Jigs and Fixtures for Resistance Welding Machines. H. C. Cogan. *Welding Journal,* N. Y., Vol. 15, July 1936, pages 9-15. A fixture holds and locates the work and is permanently attached to the welding machine. A jig does the same but is either portable or fixed so the welder can be brought to the work. Metals used for electrode tips, jigs and fixtures are discussed with emphasis on non-magnetic materials of construction for jigs and fixtures, such as Al bronze, Al and alloys, Ni cast iron, Cu. 13 rules are given for efficient operation. Discussion of series, multiple and indirect flash, seam, projection welding given with sketches. WB (7b)

The Gas Welding of Pressure Vessels and High Pressure Piping. W. A. Duncan. *Canadian Machinery,* Vol. 47, June 1936, pages 50-58. Paper at Interprovincial Boiler Inspectors Conference, Toronto, June 2, 1936. Discussion of Lindeweld method of welding with excess acetylene, to which is ascribed the production of welds free from inclusions, porosity and having high ductility due to reducing atmosphere of the flame. Diagrammatic comparison of above method with neutral flame welding is made and max. temperature for first is 2731° F. as against 2912° F.+ for latter. The use of above method with multiflame torches and semi automatic equipment is suggested for future high speed and low cost welding. Advantage of welded piping is reviewed. Procedures and rules of testing of pipe welds for welder qualification in Canada are detailed. WB (7b)

Welding of Aluminium-Magnesium Alloys. Fr. Eggelsmann. *Metal Industry,* London, Vol. 48, June 26, 1936, pages 711-715. A paper presented to the International Congress of Acetylene, Oxy-Acetylene Welding and Allied Industries. The author describes the procedure evolved for the successful welding of Al-alloys containing Mg. It was found that if attention was paid to the formation of a uniform underbead and a suitable flux was employed that slag-free and non-porous welds could be obtained. The alloy used had the following composition: Si 0.90%, Mg 1%, Mn 0.5%, Al-remainder. Test welds were made on plates 10 mm. thick and sheets 2.3 and 4 mm. thick. Autogal D was found to be the most satisfactory flux. Precautions to be closely observed are cleanliness, the use of freshly prepared flux paste, selection of the proper size of blowpipe and the use of a soft flame with an excess of acetylene. Micrographs of several welds are included and the grain structure of the weld is discussed. It is stated that hammering the weld, even if subsequently annealed, is injurious to the weld. The type of test piece used is described and physical properties obtained are discussed. A practical application of this method of welding is described. It is the welding of 6/11 mm. tubes into end plates of the same material 70 mm. thick. The results obtained were considered satisfactory as the joint withstood a water-pressure of 4266 lb./in.^{2}. The author summarized the results as (1) welding these alloys presents no difficulties if the proper flux is used, (2) slag-free and non-porous welds can be made, (3) the structure of the weld is finer than the parent metal, (4) hammering the weld does not smooth out the sharp transition in structure and is not advised, (5) the strength of the weld is higher than that of the parent metal but elongation is lower, (6) the mechanical properties obtained satisfy all the demands placed on welded joints. HBG (7b)

Evolution of the Welded-tube Industry. Gilbert Evans. *Metallurgia,* Vol. 14, Aug. 1936, pages 95-98. History of development of welded tubing is reviewed. The Fretz-Moon process is described and its advantages over older processes discussed. JLG (7b)

The Determination of the Quality of Fusion Welded Joints. E. R. Fish. *Welding Journal*, N. Y., Vol. 15, July 1936, pages 19-21. Knowledge of exact results of operator's efforts in welding through qualification tests including physical and X-ray tests of welds stressed as necessary for procedure control. Older welded pressure vessels are entirely lacking in procedure control and many have been found unsafe to use when investigated by cutting out cylindrical coupon across the weld (see "Inspection of Welded Seams in Pressure Vessels," *Metals & Alloys*, Vol. 7, June 1936, page MA 299L/1). After fabrication it is recommended that final item of inspection include coupons from a predetermined number of feet of welded joint to test weld quality and holes in vessel plugged with threaded plug. WB (7b)

F. E. C. Erects First All-Welded Bascule Span. T. H. Gardner. *Railway Age*, Vol. 101, July 18, 1936, pages 100-104. Details of welded structure are discussed. CBJ (7b)

Chrome Molybdenum Steel for Aircraft. A. J. Herzig. *Aero Digest*, Vol. 29, July 1936, pages 32-33, 36. Discussion of SAE 4130x Cr Mo steel, heat treatment and physical properties for the treatments. Recommendations are given for welding of the steel, welding rod and heat treatment after welding. WB (7b)

The Welding of Dairy Equipment. J. Hinde. *Welder*, Vol. 8, May 1936, pages 941-942. Stainless 18-8, Inconel, Sn coating, Al and glass lining are considered best for milk tank surface in contact. Fe, Cu, Ni, Cr steels are not satisfactory. WB (7b)

Welding Metals Without Fusion by "Molecular Shock." A. H. Allen. *Steel*, Vol. 98, June 22, 1936, pages 34-36. Brief account of method developed by Antonio Longoria. High frequency electric current applied to metal heated to 700° F. breaks down molecular bond in edges of abutting pieces and they weld together. Tapped seams may also be welded, result resembling a stitch weld or continuous spot weld, except that each spot represents current flow of 1/10 cycle, using 60-cycle power. No pressure is required on pieces to be butt welded. Equipment involves a movable table to which pieces to be welded are clamped, and a welding head under which table travels as abutting edges are joined. Equipment requires less space than present types and can be built at considerably less cost. Process has been applied successfully to thin sheets of non-ferrous metals. Line of weld in these was a thin band of slightly discolored metal, with practically no bead. Weld in 28-gage stainless steel had tensile strength within 0.1% of that of base metal. 16-gage galvanized steel sheet has been welded at rate of 64 ft./min. with low power consumption. See also "Wire Mesh and Sheets Welded Without Fusion," *Metals & Alloys*, Vol. 7, June 1936, page MA 298L/6. MS (7b)

Bronze-Welded Monel Metal. O. C. Jones. *Welding Journal*, N. Y., Vol. 15, July 1936, pages 18-19. Brief discussion of building up of worn Monel laundry equipment by depositing bronze and finishing to original size. Photos illustrate the built up sections. WB (7b)

Building-up by Welding of Frogs and Rail Crossings (Aufschweissen von Herzstücken im Geleise) F. Golling. *Autogene Metallbearbeitung*, Vol. 29, June 1, 1936, pages 166-171. Experiences of the German and Polish state railways are reported, great economies have been made in building up worn parts by welding which formerly were sold as scrap. The welding rod that gave best results had a composition of 1.2% C, 0.2% Mn, 0.12% Si, 0.9% Cr, 1.7% W. It assumed finally, under the cold-rolling action of the wheels, a Brinell hardness of 280, and the built-up part showed little, uniform wear in service. If more Cr and C is contained in the added material the weld is liable to spall or small pieces break off. The procedure is described in full. Ha (7b)

Handling Distortion in Maintenance Welding Operations. George W. Hettrick. *Canadian Machinery*, Vol. 47, Jan. 1936, pages 51-55. See *Metals & Alloys*, Vol. 7, Mar. 1936, page MA 128R/6. WB (7b)

Supplies Flame-Cut Steel Shapes. Fred B. Jacobs. *Steel*, Vol. 98, June 15, 1936, pages 38-40. Describes and illustrates some of the flame-cutting operations performed at plant of Reliable Steel Plate Co., Cleveland, O., in producing a wide range of shapes in thicknesses from 3/16" to 12". Machine mounted natural-gas torches are used. It is claimed that flame action with natural-gas does not case-harden stock at kerf sides. MS (7b)

Welded Construction of Butane Powered Locomotives. George Kirtley. *Industry & Welding, Executives' Quarterly*, Second Quarter, 1936, pages 58-59. General, brief description. WB (7b)

Design of Welded Steel Structure. Robert E. Kinkead. *Welding Journal*, N. Y., Vol. 15, July 1936, pages 30-31. Brief talk reported as presented at local Pittsburgh, Pa. section of American Welding Society. Advocates non-uniformity of steel in plate, sections or structure as required for local strengthening, surface corrosion resistance as exemplified by welded inserts of low alloy high tensile steels, local hardening of rail joints and ply-sections with thin corrosion resisting surfaces. Most economical design is not structure with uniform strength material throughout, but structure where low cost material is used for low stresses and high strength material only where required. WB (7b)

A Welded Reaction Chamber. *Welder*, Vol. 8, June 1936, pages 974-976. Photographic review is given of construction of 5' I. D. vessel forged from hollow ingot with end nozzles welded in. Wall thickness of vessel was 3⅝" and it was 25' long. Vessel was set upright for welding in nozzles; gas preheat was used during welding. Hinge lugs for door and thermocouple pads were welded on. WB (7b)

Gas Holders in Spain Repaired by Electric Welding. *Welder*, Vol. 8, May 1936, pages 950-953. Details of welding discussed with illustrations. WB (7b)

Join Your Metal Parts
- - Neater, Cheaper and Stronger

—by the continuous furnace brazing process

The above illustration shows the discharge end of one of our continuous copper brazing furnaces, brazing a three-piece pulley assembly. The assembly comes out securely joined—clean and bright.

Products ranging from small metal radio tube parts to heavy automotive and refrigerator units are neatly and economically joined in continuous and batch type brazing furnaces we have built.

Investigate the brazing process for your products. Additional information on brazing furnaces and the brazing process gladly furnished on request.

Welding Rock Drills (Schweissungen an Erdbohrern) Fr. Riedig. *Elektroschweissung*, Vol. 7, May 1936, pages 87-89. Instead of diamonds, layers of W carbides are welded on the edges of rotary-drills. Powdered W carbide is strewn on the edges of the tool and melted down with the direct C arc. The first layer is partially dissolved in the surface of the steel, therefore 2 or 3 layers are necessary if the highest hardness is desired. Percussion drills are welded with "Verdur," a mixture of W carbides in a thin tube of alloyed steel, which is used like a normal welding rod. Widia is welded upon rotary-drills with rods of "Diaweld." These rods possess a low melting point, therefore they are melted down with the flame. "Verdur" and "Diaweld" give tools of high ductility. HR (7b)

Advantages of Welded Construction of Power Presses. E. Wiedmann. *Industry & Welding, Executives' Quarterly*, Second quarter, 1936, pages 65-67. Advantages are appearance, greater strength and wider adaptability. Evolution of presses from cast to welded design is shown. Large vertical and horizontal swaging presses are illustrated as weld designed. WB (7b)

Welded Construction at Hiram Walker Plant. L. P. Weiner. *Industry & Welding Executives' Quarterly,* Second Quarter, 1936, pages 60-62. Welded kettles, fermenters, etc., preferably have a welded, flush interior construction in order to provide total enclosure against air contamination, recovery of CO_2 for Dry-Ice and to prevent lodging of grain on walls such as would occur on other seamless, flush type structures. WB (7b)

The Oxygen Lance. *Oxy-Acetylene Tips,* Vol. 15, Aug. 1936, pages 173-178. Uses of the oxygen lance which simply consists of a pipe through which O flows under regulated pressure, are described for other industrial processes than opening tap holes in blast-furnaces or open-hearth furnaces, e.g. cutting holes in ferrous metals by introducing O into an already started Fe oxidation reaction, or in non-ferrous metals where the lance supplies the entire amount of heat required for producing a fluid slag by reaction with the Fe oxide. Operation of the lance is described in detail for several operations. Ha (7b)

Machine Cutting—A Modern Production Tool. *Oxy-Acetylene Tips,* Vol. 15, May 1936, pages 101-106. The many advantages of oxy-acetylene machine cutting in industrial manufacturing processes are reviewed and examples described. Ha (7b)

$3700 Saved is $3700 Earned. W. B. Boom. *Industry & Welding, Executives' Quarterly,* Second Quarter, 1936, page 63. Brief description of large steel press brake for bending shapes. It will bend plate 16′ long and ¾″ thick in 15 seconds. Machine is entirely welded; construction and costs saved are itemized as, $2,000 in elimination of 16 patterns, machining costs $1500 less, savings on pattern drawings about $200. WB (7b)

Arc Welded Highway Bridges in Tasmania. G. D. Balsille. *Welder,* Vol. 8, Apr. 1936, pages 914-916. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 131L/8. WB (7b)

Residual Stresses in Arc-welded Plates. N. S. Boulton & H. E. Lance-Martin. *Electrical Review,* Vol. 118, Apr. 24, 1936, pages 601-602; *Sheet Metal Industries,* Vol. 10, June 1936, pages 481-482. See *Metals & Alloys,* Vol. 7, Sept. 1936, page MA 450L/8. MS + AWM (7b)

Welding Aluminum Bronzes (Considerations sur la Soudure des Bronzes d'Aluminium) A. Boutté. *Cuivre et Laiton,* Vol. 9, Aug. 30, 1936, page 375; *Sheet Metal Industries,* Vol. 10, July 1936, page 563. Paper presented at the 12th International Congress of Acetylene, Oxy-Acetylene Welding and Allied Industries in June. Mechanical properties of 85-90% Cu and 9-10% Al are discussed. They can be forged, hammered cold and hot, are non-oxidizing up to 800° C. and are not attacked by many chemicals. The heat treatments to increase hardness are described; quenching from 800° C. increases hardness and reduces elongation after drawing at 400° C. while it is the reverse after drawing at 500° C. Sheets of 0.5 to 24 mm. can be welded successfully if a suitable flux containing cryolite is employed. Ha + AWM (7b)

Regulations for Welded Steel Road Bridges with Full-Walled Girders (Vorschriften für geschweisste vollwandige stählerne Strassenbrücken) *Zwanglose Mitteilungen des Fachausschusses für Schweisstechnik im Verein deutscher Ingenieure,* No. 29, July 1936, page 7. The German specifications are compiled in the DIN E-4101. The necessity for paying attention to the dynamic stresses in such structures is particularly stressed. Ha (7b)

Institution of Mechanical Engineers—Welding Research Committee's Second Report. *Welding Journal,* London, Vol. 33, May 1936, pages 144-148. Extracts of the report are given. Rather than make a survey of electrode composition and manufacture for best welding conditions the committee undertook a program of utilizing a few typical commercial electrodes for the welding tests on 4 groups of steel plates graded as to tensile strength as grade (1) 22-24 tons/in.^{2}, grade (2) 27½ tons/in.^{2}, grade (3) 31½ tons/in.^{2}, grade (4) 35 tons/in.^{2} The weld metal was investigated as to physical properties, effect of annealing and normalizing on these properties, corrosion resistance; X-ray and spectra analyses were also made. The welded plates were examined in as welded, normalized condition (900°-910° C.) and after low temperature anneal. Short time tensile, long time creep, Izod, aging tests (impact) at 250° and 450° C. aging tests (impact) after water quenching from 730° and 650° C.; cold bend, repeated impact tests were made on the welded plates. Conclusions are: (1) C and Mn of weld may differ widely from electrode, (2) an extra layer of weld metal laid over a V weld may produce an appreciable depth of normalizing of the weld metal, (3) cavities and inclusions exist in all welds except the best and may reduce fatigue range of weld; X-ray shows location, size and number of cavities and inclusions, (4) creep of weld metal about same as mild steels, at boiler temperatures without preheat there is no creep danger, (5) impact results indicate no danger from embrittlement in boiler service, (6) bend test should include % elongation of weld metal at surface of the V after bending, (7) repeated stress resistance for welds is less than for unpierced plates of same tensile strengths, (8) selection of electrode and welding technique is important for minimum cavities and inclusions in weld, (9) corrosion tests indicate no greater corrosion of weld than of plate. WB (7b)

Welded Mild Steel Drums. *Welding Journal,* London, Vol. 33, May 1936, page 140. Brief note on new British specification No. 670-1936. 3 classes of drums are considered for the specifications according to corrosion hazard and specific gravities in 5 to 150 gallon capacities. Specification does not include material of lower thickness than 18 B. G. WB (7b)

Arc Welding of a Special Steel. L. Sanderson. *Metallurgia,* Vol. 14, June 1936, page 48. Discusses welding of high-Mn steel. JLG (7b)

Welding the Servel Refrigerator. R. S. Taylor. *Industry & Welding, Executives' Quarterly,* Second Quarter, 1936, pages 42, 44. Brief details given. Both gas and arc welding used. WB (7b)

Welded Stainless Equipment. George H. Tay. *Industry & Welding, Executives' Quarterly,* Second Quarter, 1936, pages 68-69. Cookers, storage and mixing equipment for foods are made of welded stainless with welds ground flush with plate. Satin finish for polish is sufficient for most materials though high polish is necessary for corrosive materials. No welds are made in corners where joint cannot be ground because of danger of contamination and fermentation from food lodged there. When properly welded and polished the joint is practically invisible. WB (7b)

Welding in the Manufacture of Salt. S. H. Zimmerman. *Industry & Welding, Executives' Quarterly,* Second Quarter, 1936, pages 55-57. Welding was chosen for evaporators due to reduction in weight and cost and assurance of tight joints. Repairs and installation of Monel plates are done by means of welding. Removal of gypsum incrustation from inside of tubes is now done with arc weld hard-faced bits which outlast former tempered steel bits in ratio of 7-1. Necessity for smooth walls on evaporating equipment and conveying belts made of monel requires us of welding rather than riveting. WB (7b)

Welding Sensitivity (Heat Cracking) (Zur Frage der Schweissempfindlichkeit) K. L. Zeyen. *Technische Mitteilungen Krupp,* Vol. 4, Aug. 1936, pages 115-122. Weld sensitivity or heat-cracking is that phenomenon in metallic materials which occurs during or after welding and consists in formation of cracks along the seams. In general, welding sensitivity increases with decreasing thickness of the material, with increasing strength of the material, and with increasing complexity of the structure to be welded. The causes can be outside the material, i.e. incorrect design and defective workmanship, or defective material. The former comprise overheating, welding on one side if previously another weld was made at the same place on the other side, improper cooling, sequence of welding. The causes are often seen to be unsuitable welding rods, e.g. high C steel or high alloy steel which produce hard welds. Welding sensitivity of alloy steels increases with increasing Mo, Cr and Mn content, and in C steels with increasing P and S content; the maximum content of P + S should not exceed 0.035%. Open-hearth steels are in general much more weld-sensitive than electrically produced steels. A further cause of heat-cracks was found in wrong heat treatment or cold working which result in excessive strains, and can be prevented by air-normalizing before welding. Test results are given in detail. 9 references. Ha (7b)

Electric Arc Welding and Its Applications. XII. M. MAURICE LEBRUN. *Welding Journal,* London, Vol. 33, May 1936, pages 134-137. Practical discussion of application of arc welding methods for joining plates, ribs, angles for ships and for liquid transportation tanks under high pressure. WB (7b)

Autogenous Welding and Ship Boilers (Soudures Autogène et les Chaudières de Navires) M. LEBRUN. *Usine,* Vol. 45, May 14, 1936, page 31. Advantages in welding the boilers of a passenger liner are briefly discussed. Ha (7b)

Double-Track Bascule Span Employs Welded Design. HEATH LAWSON. *Engineering News-Record,* Vol. 117, Sept. 17, 1936, pages 408-409. Erection and field welding of bridge are discussed. CBJ (7b)

Correct Preparation for Electric Resistance Welding (Schweissgerechte Vorbereitung zur elektrischen Widerstandsschweissung) W. KÜRSCHNER. *Elektrowärme,* Vol. 6, Aug. 1936, pages 239-241. Points to be observed in properly handling the material and arranging the welds and precautions to take when sections of largely differing dimensions must be butt-welded together are discussed. Ha (7b)

Investigations on the Fatigue Limit of Welds in Steel 52 (Untersuchungen über die Dauerfestigkeit von Schweissverbindungen an St 52) A. MATTING & G. OLDENBURG. *Elektroschweissung,* Vol. 7, June, 1936, pages 108-111. An explanation of the low fatigue limit of welds is found in the difference of elastic limits between the weld and the welded material. It is assumed that the phenomenon is governed by other factors also. HR (7b)

The Training of Welders, Supervisors and Draughtsmen. III, IV, V. H. MARTIN. *Welder,* Vol. 8, Apr. 1936, pages 923-924; May 1936, pages 948-949; June 1936, pages 984-985, 989. Series of articles giving directions for teaching students the welding of plates at right angles to each other, which covers 70% of welds in field, and butt welding. Part V discusses contraction stresses. The stress relief of structures with widely varying cross sections is considered to be dangerous and the practice of balancing welding cycles to oppose contraction strains is recommended. WB (7b)

Do Alloying Elements Burn Away when Welding Light Metals (Findet beim Leichtmetallschweissen ein Abbrand von Legierungsbestandteilen statt)? M. MAIER. *Aluminium,* Vol. 18, Aug. 1936, pages 373-374. Tests showed that no appreciable accumulation of the more difficultly burning constituents, nor a reduction of the easily oxidizing constituents takes place. The use of a flux reduces the burning of Si. Ha (7b)

Toronto Welding Practice Standardized—The Way Department of the T. T. C. Has Standard Methods for Doing Various Types of Repair Work on Rail Joints and Special Track Work. W. A. Arc Welded High Pressure Vessels (Elektrisch geschweisste Hochdrucktrommeln) FRANZ NEHL. *Elektroschweissung,* Vol. 7, May 1936, pages 81-86. Vessels for pressures over 60 atm. are seldom welded with watergas as with ordinary steel the thickness of walls is too great and for alloy steels watergas welding is not suitable. Welds in high pressure vessels must possess a tensile strength not less than 90% of the sheet and endure a bending test over 180°. These requirements are met by heavy coated rods of ordinary steel, but with this the necessary tensile strength at elevated temperatures cannot be reached. In order to do so, coatings are provided with an addition of Mo. New difficulties are encountered with vessels of alloyed steels. Rods with small additions of Ni and Cr give welds with low ductility, whereas with austenitic rods the welds cannot be annealed without danger of loss of tensile strength. Annealing is indispensable in view of the tensions to be removed after welding. Good results were obtained with Cu steels containing a small amount of Ni. The electrode contained 0.7% Cu with some Ni and the coating was given an addition of Mo. This electrode had a good flow, the Cu was transferred without loss in the weld, which moreover showed a content of 0.2% Mo. The weld was, as could be shown by microscopic and X-ray inspection, free from pores and failures. Unfortunately the bending angle did not exceed 120°. Full success was attained by the application of precipitating heat treatment (several hours at 640°-660° C.). Further advantages of Cu-steel are: absence of hot-shortness and diminution of scale in consequence of electrochemical effects, high tensile strength at normal and elevated temperature. Mechanical properties obtained in practical tests are:

	Sheet			Weld		
temperature °C	yield-point kg./mm.²	tensile-strength kg./mm.²	elongation %	yield-point kg./mm.²	tensile strength kg./mm.²	elontion %
20	34.4	53.6	27.0	34.6	54.2	19.2
200	31.0	47.9	24.1	29.8	50.1	19.9

Welded Truck Frames for B. M. T. Lines. Multi-Section Cars. G. D. SPACKMAN. *Welding Journal,* N. Y., Vol. 15, July 1936, pages 27-30. Experimental truck frames were built up of welded Cromansil steel. A large number of cars were ordered with welded trucks using pressed plate members of Cromansil and electric furnace castings of Cromansil analysis. Design stress in trucks is approximately 24,000 lbs./in.^{2} which is about 40% of endurance limit for parent metal in rotating beam tests. All trucks are heat treated after welding even though low C content of .17% is not dangerous in welding heat region. Destruction tests made on a truck frame indicated satisfactory strength. WB (7b)

Principles and Application Possibilities of the Various Electric Welding Methods (Grundlagen und Anwendungsmöglichkeiten der einzeinen elektrischen Schweissverfahren) K. SIEMERS. *Elektrowärme,* Vol. 6, Aug. 1936, pages 230-237. The mechanism of electric arc heating, resistance welding, temperatures obtainable, types of electrodes for a.c. and d.c. welding, weldability of the different metals, and welding machines are discussed. Examples of welded parts and structures are given in illustration of the principles involved. Ha (7b)

Marion Gives Welding a Plus Rating. D. J. SHELTON. *Industry & Welding Executives' Quarterly,* Second Quarter, 1936, pages 48-50. Review of evolution of power shovel with major parts of the machine of all weld construction. Photos illustrate construction and assembly. WB (7b)

Stainless Steels. Part IV. E. C. ROLLASON. *Welder,* Vol. 8, Apr. 1936, pages 917-922. Corrosion of weld, effect on plate corrosion, fluxes for welding, soldering and brazing are discussed, several formulae for the latter being given. Brief review of effect of C in gas weld flame, expansion coefficients for various Cr and Cr Ni alloys compared with Fe and Cu for 20-100° C. and 20-600° C. and effect on welding strains are discussed. Curves are given for Brinell of 18-8 stainless rolled 50% and annealed at 500°-1150° C. with .09 C, 3.9 Mo, .67 Ti; curve for 22-9 stainless with 2.4 Si is compared with mild steel. Curves are also given for Brinell vs. % reduction in cold rolling as indication of work hardening of 18-8 showing effect of addition of .09 Ni, .05 C, 3.9 Mo, and .67 Ti, to 18-8, .25 Si to 22-9 stainless as compared with 13.5 Cr and mild steel. Largest increase in hardness occurs in 18-8 having .09 C, then .05 C, .67 Ti, 2.5 Si, and 3.9 Mo last. Table of mechanical properties of various stainless steels is included. Short time tensile and creep data are given for low and high carbon 18-8 respectively. WB (7b)

Special Fabricating Methods Employed in Making Heat Exchanger Tank. F. M. YOUNG. *Steel,* Vol. 98, May 25, 1936, pages 64,66. Describe methods used in fabricating unit used in brine holdover system of mechanical refrigeration for railroad air conditioning. Tank is made of 2 pieces of steel plate, edges of which are turned in and welded together electrically, forming guides which support coil. Bottom plate is placed inside the tank ¼" from bottom. Bead is welded electrically around inside of tank against outer surface of bottom plate. Fe bands are welded around tank at several places to reinforce it. MS (7b)

8. FINISHING

H. S. RAWDON, SECTION EDITOR

Selection, Application and Use of Finishes for Metal. *Steel*, Vol. 98, Mar. 16, 1936, pages 32-35; Mar. 30, 1936, pages 53-54, 56-57; Apr. 13, 1936, pages 48-49, 56; Apr. 27, 1936, pages 48, 50, 52; May 11, 1936, pages 70-72; May 25, 1936, pages 50, 52; June 8, 1936, pages 40, 42, 46; June 22, 1936, pages 47-48, 50. Discusses the subject from user's point of view. Outlines basic factors on which selection of finishes depends and then deals with various finishes available, including metallic coatings, organic finishes, and surface conversion treatments, and testing of organic coatings. MS (8)

■ 8a. Pickling ■

Etched Stainless Steel opens new Fields to Architects and Designers. *Steel*, Vol. 98, May 18, 1936, page 45. The usual procedure in etching 18-8 Cr-Ni stainless steel requires a solution of $FeCl_3$ or HCl as etching agent. Solution is either agitated by air or the plates are moved in the solution. About 30 min. is required to etch to a depth of 0.003″. Etched plates are washed thoroughly in running H_2O and then immersed in HNO_3 to restore passivity. Etched portion may be filled with colored enamel if desired. MS (8a)

Effect of Time, Temperature and Concentration of Sulphuric Acid upon the Rate of Pickling. G. L. Bryant & F. R. Porter. *Better Enameling*, Vol. 7, Jan. 1936, pages 18-20, 28. 2″ x 2″ plates were sheared from 20 gage enameling stock, cleaned to remove grease, dried, and weighed on an analytical balance. They were pickled for periods of 10, 20, 30, 40, and 50 minutes in 4%, 6%, and 8% by weight of H_2SO_4 at 140°, 160°, 170° and 180° F. The pickled panels were rinsed in water, dried, washed in alcohol, and weighed. Increase in temperature greatly increased the rate of reaction. Increase in concentration of acid from 4% to 8% increased the rate of reaction up to 6%, with an increase from 6% to 8% the rate decreased. An increased pickling period increased the rate at 140° and 150° F. with 4% acid and at 140° F. with 6% and 8% acid. Increasing the time of pickling at 170° and 180° F. with 4% acid and 160°, 170°, and 180° F. with 6% and 8% acid did not increase the rate. Increasing the pickling period increased the weight loss in every case studied but not the rate of reaction. Standard pickling practice in porcelain enamel industry of 6% H_2SO_4 at 160° F. is thus indicated as being good practice. CBJ (8a)

Treatment of Galvanized Sheets for Painting. J. L. Schueler. *Journal American Zinc Institute*, Vol. 17, 1936, pages 93-98. Wherever possible the sheet should be allowed to age or weather before paint is applied. If that is not possible etching should be used. When a chemical etchant is employed it is important that the action is not too strong. Acids should be avoided. A neutral solution of $CuSO_4$, or $SbCl_3$ works well. The Zn surface must be dry and free from all foreign material before paint is applied. BHS (8a)

Rational Use of Inhibited Pickling Baths for Ferrous Components. P. Mabb. *Sheet Metal Industries*, Vol. 10, July 1936, pages 537-539. The author points out that the speed and other merits of the usual pickles are not diminished by inhibitors. Acid consumption is reduced and over-pickling eliminated. 4 curves show the decrease in weight loss brought about by various inhibitors. AWM (8a)

The Spoilage of Non-ferrous Components by Acid Pickling. E. E. Halls. *Metallurgia*, Vol. 14, Aug. 1936, pages 91-93. Discusses bright pickling of Cu-base alloys. The concentration of the acid bath, its temperature, and immersion period must be kept within narrow limits. A number of recommended acid baths are given together with data on rate of solution of alloys in various other baths. JLG (8a)

■ 8b. Cleaning including Sand Blasting ■

Sandblasting Apparatus with Centrifugal Projection without Compressed Air (Appareils a Jet de Sable à Projection centrifuge sans air comprimé) E. Monnot. *Revue de Fonderie Moderne*, Vol. 30, June 25, 1936, pages 211-214. Principle of the machine and range of application are described; the method is less suitable for small pieces and for very large pieces of irregular shapes than sandblasting with compressed air. Ha (8b)

Cleaning Sheet Metal Parts for Porcelain Enamel. *Better Enameling*, Vol. 6, July 1935, pages 18-19, 24-27. In cleaning, the removal of oil and grease is accomplished either by an anneal or by caustic soda and other alkali usually in boiling solution. H_2SO_4 or HCl pickling solutions are commonly used to remove rust and scale. Ni plating has proved advantageous in preventing enameling defects such as fish scale and in improving the adherence of the enamel. Equipment used and control methods are discussed. CBJ (8b)

Sand- and Shot-Blasting. J. H. D. Bradshaw. *Foundry Trade Journal*, Vol. 54, Mar. 12, 1936, pages 205-208. Paper read before the Sheffield branch of the Institute of British Foundrymen. Hardness determinations of particles of chilled-steel abrasive made with the Firth Hardometer using the diamond indenting tool indicate a Brinell diamond hardness from 750 to 875. Nozzles worn beyond the limit of good practice increase the total sand-blasting costs by many times the price of new nozzles. Nozzles are usually made of a hard white cast Fe, but gas tubing is sometimes used. Commercial nozzles are now available which have a guaranteed working life of 1500 hrs., during which time the outlet will not enlarge more than 50% of its original diameter. This nozzle is mild steel lined with Norbide (boron carbide, B_4C). AIK (8b)

A Centrifugal Method of Cleaning Castings. Martin H. Kidder. *Better Enameling*, Vol. 6, Nov. 1935, pages 14-18. Discusses cleaning by tumbling and by a blast of abrasive thrown centrifugally and tangentially against the work by a mechanical device. CBJ (8b)

Cleaning and Prime-coating the Surfaces of Heavy Machinery. E. A. Zahn. *Industrial Finishing*, Vol. 12, May 1936, pages 13-14. **Cleaning Small Steel Parts Preparatory to Finishing.** June 1936, pages 20, 22. **The Dangers of Rust.** July 1936, pages 19-20. **Prime Coating in the Foundry.** Aug. 1936, pages 19-20. The first 4 of a series of 20 articles on industrial finishing. Part I, shows advantage of blasting over other methods of cleaning. Priming coat should be applied immediately after cleaning and all parts must be cleaned before each coat of paint if they have been handled. Part II describes briefly the various cleaning solutions, their application and merits. Part III, emphasizes the importance of removing rust from metal prior to painting; application of paint to rusted articles is not recommended. Part IV, recommends the prime coating of castings before they leave foundry as this will eliminate rusting and subsequent paint failures. VSP (8b)

Cleaning Cast Iron Parts for Porcelain Enameling. *Better Enameling*, Vol. 6, Aug. 1935, pages 14-18. Various types of sandblasting are described. CBJ (8b)

■ 8c. Polishing & Grinding ■

Burnishing Procedure for Aluminum Screw Machine Products. J. F. Coneen. *Metal Industry*, New York, Vol. 34, Aug. 1936, page 301. Equipment, materials, and procedure in burnishing Al screw machine products are described. CBJ (8c)

Honing of Cylinder Bores (Das Honen von Zylinder-Bohrungen) Koch. *Oberflächentechnik*, Vol. 13, Aug. 4, 1936, pages 173-175. Principles and development of methods for finishing processes by honing are discussed; the modern process of honing combines a rotating motion with a reciprocating motion whereby the honing tool is pressed against the cylinder wall. The principal advantages are accuracy and speed. Ferrous alloys of any hardness can be honed with advantage but non-ferrous metal cannot so far be honed successfully as the honing stones clog and smear up. Procedures, mechanical and automatic equipment and cooling methods are described. Ha (8c)

Barrel Burnishing. Walter R. Meyer. *Metal Industry*, New York, Vol. 34, Mar. 1936, pages 101-102. Extended abstract of "Das Polieren in Trommeln," F. Schwarz, *Oberflächentechnik*, Vol. 12, No. 20, 1935, pages 243-247. See *Metals & Alloys*, Vol. 7, June 1936, page MA 302R/6. CBJ (8c)

■ 8d. Electroplating ■

Bright Nickel Plating. A Critical Study. L. E. Stout. *Electrometallurgy*, supplement to *Metal Industry*, London, Vol. 48, June 26, 1936, pages 722-723. The article is from a recent address to the American Electro-Platers' Society describing a series of studies of commercial "addition agents or brighteners" for producing "bright Ni." Each was studied under its prescribed conditions, was tested by adding it to a single salt bath of $NiSO_4$ 12 oz., $NiCl_2$ 4 oz., boric acid 2 oz., H_2O 1 gallon, and also compared with the commonly used addition agents as lactic acid, malic acid and glucose. This study was not a theoretical one, but rather to obtain practical information for the plater. Only under the prescribed conditions could good results be obtained. In his experience the author has not, as yet, been able to obtain bright plated Ni that could be called "brilliant" or comparable to a properly buffed nickeled surface in taking a deposit of Cr. HBG (8d)

"Trouble-Shooting" on Electroplating Generators. L. L. Stoffel. *Metal Industry*, New York, Vol. 34, Sept. 1936, pages 339-341. Cures for common troubles which occur in routine practice are discussed. CBJ (8d)

Some Recent Developments in Chromium Plating. Herbert R. Simonds. *Iron Age*, Vol. 138, July 16, 1936, pages 38-42, 114. Considers the high lights of Cr plating as now practiced almost universally, and describes 2 new methods developed in England. One of these developed by Coleman & Appleby, Ltd., and marketed in this country by Nickel & Chromium Products Co., consists in an addition of secret composition to CrO_3 and hot H_2O to produce a plating bath ready for use. Quantity added amounts to about 1/15 of CrO_3 used which must be of high purity. Tank and anodes are made of high-grade antimonial lead but in England glass-lined tanks are generally used. The other English development is brush plating which consists in attaching the negative wire of low voltage d.c. to the work and positive wire to binding post on end of brush which has a metal anode in center. Ni plating can also be done by this method. Thorough cleaning, buffing and polishing are necessary preliminary operations for both processes. VSP (8d)

Nickel and Chromium Plating of Zinc and of Die-Cast Zinc (Nichelatura e Chromatura dello Zinco e dello Zinco fuso sotto Pressione) V. P. Sacchi. *Industria Meccanica*, Vol. 18, June 1936, pages 334-339; July 1936, pages 417-423. Exhaustive review of literature on procedures to obtain good deposits, defects most common in these deposits, properties of deposits from acid and basic plating baths, and stresses occurring in the deposits. 67 references. Ha (8d)

Nickel Anodes (Nickelanoden) E. RAUB. *Mitteilungen des Forschungsinstituts und Probieramts für Edelmetalle,* Vol. 10, July 1936, pages 37-43. Scarcity and high price of Ni in Germany make it desirable to use insoluble anodes of either C, Pb or rustless steel in plating baths instead of soluble Ni anodes. However, in baths with high chloride content, the latter 2 materials were strongly attacked; besides, the varying Ni content of the bath due to insoluble anodes is not conducive to good deposits. A satisfactory method, although expensive, uses metallic anodes made by electrolysis of Ni salts. The most suitable anode shapes are discussed which should be as pure as possible. Of the usual impurities, Mg is particularly harmful as it soon leads to disintegration of the anodes in the bath. Fe has no harmful effect on the solubility of the anodes, even in large amounts. The effect of Cu up to 0.2% could not be stated. Zn and Mn can have undesirable effects. The quality of the deposits is not affected by Mg in the bath; it is even of advantage in that it produces soft deposits, so that sometimes Mg salts are added to the electrolyte. Cu is harmful in the bath as it is deposited on the cathode and produces dark deposits; even 0.005 g./l. is obnoxious. Fe also is harmful in the bath. In small amounts it produces finer grain and brighter deposits, but in larger amounts it leads to spalling and scaling. Baths with more than 0.5-1.0% Fe with respect to the Ni content are absolutely useless. Mn has less influence than Cu, but as it accumulates more quickly than Cu, since it is not deposited as quickly as Cu at the cathode, the adhesion of the deposits suffers. Zn in very small amounts produces brighter deposits; in larger amounts, however, dark stripes appear on the deposit. The limit for Zn content should be 0.05-0.1% Zn with reference to Ni. The preferable thickness of plate anodes is 5-8 mm. Cast anodes of less than 5 mm. are produced with difficulty. Ha (8d)

Dry Rectifier Supplies Current for Operating Electroplating Unit. *Steel,* Vol. 98, June 29, 1936, page 46. Describes a rectifier-powered unit for Sn-plating automotive pistons. Size rated at 300 watts will plate 8 pistons at a time with 60 cycle, 110-volt a.c. Rectifiers are of the CuS type, about 12 volts being applied to input side to deliver 6 volts at tank. With continued use it is necessary to apply 13 volts. Plating bath used is of the alkali-Na_2SnO_3 type and is sole supply of Sn. No Sn anodes are used. Replenishing of bath, as indicated by periodic analysis, has been found to be sufficient. MS (8d)

Insulators Salvaged by Cadmium Plating. J. B. BOWEN. *Electrical World,* Vol. 106, Sept. 12, 1936, pages 41-42, 110-112. Corroded caps and pins are reconditioned by Cd plating. CBJ (8d)

Critical Current Density in the Deposition of Chromium (Ueber die kritische Stromdichte bei der Chromabscheidung) N. D. BIRÜKOFF. *Korrosion & Metallschutz,* Vol. 12, July 1936, pages 165-171. In electro deposition of Cr, a definite minimum current density exists below which either practically no Cr is deposited or it appears in spots. This critical current density was investigated in the range, 0°-60° C., and was found to increase with increasing temperature by reason of the increasing velocity of the chemical oxidation of the chromous Cr formed on the cathode whereby only a smaller part of the chromous Cr can be reduced to metal. Additions of small amounts of $K_2Cr_2O_7$, $KHSO_4$, K_2SO_4, $Cr_2(SO_4)_3$, $Cr(OH)_3$ and H_2SO_4 had no appreciable effect on the critical current density whereas $PbCrO_4$ reduced it and chromium-chromate increased it energetically if it had been made by heating aqueous H_2CrO_4 solution or by melting CrO_3. 12 references. Ha (8d)

Nickel-Silver Process (Das Nickel-Silber-Verfahren) H. BEHNKE. *Oberflächentechnik,* Vol. 13, Aug. 18, 1936, pages 183-184. Ni-plated articles are Ag-plated with difficulty as Ag does not adhere very well to Ni. The Ni-Ag process consists in first Ni-plating Cu, brass, or Cu-plated objects in the usual manner and then plating them in a separate bath, the Ni-Ag bath, with a Ag layer. The latter, a KCN-Ni bath containing a small amount of Ag, is a reddish-brown solution made by dissolving 1 kg. of Ni-Ag salt in 8-10 l. H_2O. The Ni-Ag salt consists essentially of Ni-Na-cyanide, NaCN, and AgCN. The bath should have a density of 12° Be and be operated with C anodes. The Ni-plated parts are first treated about ½ min. at 4-5 v. and 3-4 amp./dm.^{2} current density whereby a gray deposit is formed with strong H development. The voltage is then reduced to 2-3 and the parts are left for 2-3 min. further in the bath whereby the deposit becomes gradually lighter and finally has a bright silver-white appearance. If the parts are left in the bath longer than 5 min., the brightness is dulled again. Simultaneous deposition of Ni together with Ag is possible only by keeping the Ag concentration of the bath as low as possible and the voltage as high as possible. Theoretical reasons for this are advanced. Such deposits do not tarnish as easily as pure Ag deposits but without lacquering they are not as tarnish--resistant as an ordinary deposit coated with a good lacquer. 6 references. Ha (8d)

The Diesel Engine in the Plating Plant. C. E. DIETLE. *Metal Industry,* New York, Vol. 34, Sept. 1936, pages 344-345. Diesel engine operation and economy are discussed. CBJ (8d)

Preparation and Protection of Metallic Surfaces (Preparación y protección de superficies metálicas) L. R. DE RIVERA & PUIG D'ASPRER. *Metalurgia y Construcción Mecánica,* Vol. 2, July 1936, page 3; Aug. 1936, page 7. Brief review. FRM (8d)

Defects and Errors in Nickel Plating, Their Causes and Prevention (Die Fehler beim Vernickeln, ihre Ursachen, ihre Abhilfe) A. DARLAY. *Oberflächentechnik,* Vol. 13, Aug. 18, 1936, pages 184-186. Detailed description is given of means and procedures to prevent the baths becoming too alkaline or too acid, streaky deposits, crystallization in the bath, porous deposits, cracks and incorrect thickness of deposits. Ha (8d)

Nickel Plating Brought Up-to-date. GEORGE B. HOGABOOM. *Metal Industry,* New York, Vol. 34, Aug. 1936, pages 298-300. Rule-of-thumb methods have been supplanted by modern methods embodying scientific control and automatic continuous equipment. CBJ (8d)

Testing Plated Products for Quality. SAM TOUR. *Metal Industry,* New York, Vol. 34, June 1936, pages 222-224. Tests for determining the quality of plated products include salt spray corrosion test, ferroxyl test for porosity, bend tests for adherence, and metallographic examination to determine variations in thickness of the deposits and, hence the throwing power of the bath. CBJ (8d)

RODINE

is cutting costs in 95 per cent of the country's pickling rooms.

RODINE

more than pays for itself. By its use, economies of 30 to 60 cents per ton of metal pickled are frequently gained.

RODINE

eliminates pitting of the metal. Minimizes acid brittleness. Reduces rusting of pickled stock.

RODINE

makes pickling operation easily controlled and gives consistent results.

Polarization Potential in the Cathodic Deposition of Zinc from the Aqueous Solution of Zinc Sulfate. T. ISIHARA, T. ONODA & K. UMETU. *Kinzoku no Kenkyu,* Vol. 12, Aug. 1935, pages 381-396. In Japanese. The report is the second on the subject and is concerned with the effect of gelatin and glue added to the acidified solution of $ZnSO_4$. The electrolyte is from 1 to 2 N with respect to $ZnSO_4$ and 0.5 to 1.5 N H_2SO_4, glue or gelatin being added in amounts of 0.025 to 2.0 g./l. The single potential of the cathode, the minimum overvoltage of 0 and the decomposition voltage have been found to decrease with increase in H_2SO_4 concentration and the tendency is greater in the presence of colloids. More complex features are observed in some of the current density-polarization curves. In electrolytes containing glue, polarization is diminished by the addition of acid as long as the current density is low and the amount of colloid is small, while the reverse is the case if the current is high. The discontinuity mentioned in the first report was also observed in electrolytes containing glue at about 0.1 g./l. In case the amount of glue surpasses this limit the current density-polarization curves show abrupt changes in the neighborhood of 60 milliamps/cm.^{2}. The effects of gelatin are somewhat more complex but are smaller. YO (8d)

Standard Quality for Plated Tableware. F. C. MESLE. *Metal Industry,* New York, Vol. 33, Aug. 1935, pages 283-289. Quality marks should indicate the basis metal, the average plate thickness, and its thickness at special wear points. A practical method for measuring the thickness consists in drawing the curved object over a flat file until the Ag is removed and measuring the diameter of the exposed part. The thickness on a flat surface is determined by using a fine abrasive wheel of a known radius and measuring the diameter of the spot exposed by the wheel. CBJ (8d)

Some Properties of Nickel Electrodeposits. ROBERT J. MCKAY. *Metals & Alloys,* Vol. 7, Aug. 1936, pages 193-198. Bath control is discussed under variables of pH, current density, cleanliness of work and bath, temperature, oxidation of evolved H_2 and composition. Thickness of 0.0004" to 0.21875" are obtainable. Greater difficulty is encountered and nicer control is required in producing heavy plates. Brilliancy of finish of the plate is discussed together with effect of additions to the bath for producing a bright finish. Hardness of electroplated Ni can be varied from that of fully annealed metal to a hardness greater than that obtainable by cold work. Ni tends to follow the crystal structure of the basis metal less than other electroplated metals. Adherence depends ordinarily on care in preparation of surface. Throwing power and costs are briefly discussed. 13 references. WLC (8d)

Plating Rhenium and Rhenium-Nickel Alloys. C. B. F. YOUNG. *Metal Industry,* New York, Vol. 34, May 1936, pages 176-177. History and properties of Re are discussed. Pertinent data on Re plating and Re-Rh plating are given. An alloy of Re and Ni has also been plated out. CBJ (8d)

The Bek Process. LOUIS WEISBERG. *Metal Industry,* New York, Vol. 34, Aug. 1936, pages 295-297. Au plating followed by heat treatment to produce diffusion is the basis of a method of jewelry manufacture known as the Bek process. CBJ (8d)

Recent Developments Open Path to Wider Use of Bright Zinc Plating. M. B. Diggin. *Steel,* Vol. 98, Apr. 20, 1936, pages 44, 46. To compete with Cd plating in ease of application, a bright Zn plating process should have the following characteristics (a) produce uniformly bright deposits requiring no bright dip; (b) solutions should be as stable as ordinary cyanide plating baths; (c) bath should operate over reasonably wide range of operating condition, be insensitive to small amounts of impurities, and be capable of control by simple methods of analysis; (d) anode and cathode efficiencies should be balanced, and permissible cathode current density should be high; (e) no insoluble materials should be formed; and (f) deposits should be free from porosity and brittleness, firmly adherent, and should afford as good protection against corrosion as ordinary Zn deposits of same thickness. A process claimed to fulfill these requirements operates at a current density of 40-60 amps, with tank voltage of 3-4 volts. Solution is operated at 75°-110° F. and volume should be such that not more than 2.5 amps./gal. is passed. Special anodes are required, which produce no sludge and do not polarize when left in the solution. Anode area should be about 50% greater than that of cathode. Anode-cathode spacing varies from 7" to 12" and depends on amount of recessing in work. Unlined tanks should be used for solutions. Racks should be made from Cu or brass. Large exposed rack area must be avoided. Tabulates comparative rates of plating of bright Cd and the bright Zn processes. MS (8d)

The pH Number in Electroplating. I. The Measurement of the pH Number in Acid Plating Baths. II. The Measurement of the pH Number in Alkaline Baths (Die pH-Zahl in der Galvanotechnik. I. Die Messung der pH-Zahl in sauren galvanischen Bädern. II. Die Messung der pH-Zahl in alkalischen Bädern) R. Springer. *Oberflächentechnik,* Vol. 13, June 16, 1936, pages 135-136, 149-150. The definition of the pH number as measure of the acidity and amount of H ion concentration is explained, and its importance for electroplating processes and methods for its determination are described. A new indicating paper is mentioned (LWP-PEHA paper) which, similar to litmus paper, indicates by its coloration the acidity. The paper is impregnated with 7 different colors with which is compared the color it assumes on being dipped for 1 sec. into the bath to be measured. The color of the bath itself is compensated. There are 5 kinds of paper at present: a range of 5.2-5.7 pH for ordinary acid Ni baths, 3.7-5.0 pH for acid plating baths (except Zn), 3.7-5.3 pH for acid Zn baths, 1.2-3.4 pH for weakly acid Cu baths (quick plating baths), and 0.9-1.5 pH for acid Cu baths or others with contents of 5-40 g. H_2SO_4/l. Part II. Alkaline bath reaction as expressed by pH > 7 is explained and the possibility of detecting sources of defects in deposits by measuring the pH value discussed and explained by using as examples baths for brass, Cd, and cyanide baths for Cu, Ag and others. PEHA papers are available for these purposes: No. VI, range 9.5-11.0 pH for cyanide Cu, brass and Ag baths, No. VII, range 11.0-13.5 pH for cyanide Cd, tombac, alkaline Zn, alkaline Sn and degreasing baths. The pH value for brass baths should not exceed 10.2 as otherwise the deposits become spotty. Red brass deposits can be obtained by increase of pH to more than 12.5 without having to use a special tombac bath. Practical hints for the use of PEHA paper are given. Ha (8d)

Our Experience in Cadmium Plating in a Barrel. A. F. Fletcher. *Metal Industry,* New York, Vol. 33, Dec. 1935, pages 430-433. See *Metals & Alloys,* Vol. 7, Apr. 1936, page MA 194R/2. CBJ (8d)

Metal Rectifiers to Supply Current for Plating. A. Smart. *Metal Industry,* New York, Vol. 34, July 1936, pages 261-264. Discussion of the principle and construction of metal rectifiers. CBJ (8d)

The Structure of Electrodeposits. D. J. MacNaughtan & A. W. Hothersall. *Metal Cleaning & Finishing,* Vol. 7, June 1935, pages 285-288. Hardness of electrodeposits increases with decreasing grain size. In finer grained deposits, however, large changes in hardness are not accompanied by any considerable change in microstructure. Codeposition of H may affect hardness more than cold working, but it is not controlling. Solution pH, cathode potential, current density also influence hardness although exact relationships were not clear. Colloids or hydroxide precipitates at the cathode are thought to cause small grain size which increases hardness of deposits. A table is given showing Brinell hardness number and some microstructures for 12 different metals: thus Ni (from sulphate solutions) 125 to 420, variation in Brinell number being due primarily to pH changes; Ni (from solution containing colloids) up to 550; Cu (sulphate solutions) 40-62, plus colloids up to 130. See also *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 135L/9. GBH (8d)

8e. Metallic Coatings other than Electroplating

Research on Thin Layers of Tin and Other Metals. II. The Corrosion of Metals by Technical Insulating Oils. P. J. Haringhuizen & D. A. Was. *International Tin Research & Development Council, Technical Publication,* Series A, No. 35, 1936, 16 pages. Very thin layers of Pb, Sn or Cu were deposited on glass by vaporizing the metals in a vacuum. The rate of solution of this metal film in a reagent was determined by noting changes in transmission of light. Transformer oils corrode the metals at different rates, but the rates do not bear a direct relation to the acidity developed in the oils. Some other constituent much smaller in amount than the acid, is assumed to be the active agent. Cu is attacked slowly at first, then much more rapidly. After the first few hundred hours the corrosion of Pb or Sn goes on at constant, very slow, rates with Sn showing more rapid corrosion than Pb in the early stage, but less after the rate becomes constant. Sn would therefore appear suitable for protection of Cu against corrosion in such oils. Sn over Cu was not studied, however, and no comparison was made of the relative corrodibility of ordinary Cu, Ni or Pb as compared with the extremely small crystals in the vacuum-deposited films. HWG (8e)

Casting-on of Metal—A Modern Metal Coating Process (Das Angiessen von Metall—ein neuzeitliches Metallüberzugsverfahren) K. Nischk. *Oberflächentechnik,* Vol. 13, May 19, 1936, pages 111-114. The coating of a metal by casting on another of lower melting point instead of by dipping the object into a bath of the metal is described for Pb on Fe, pure Al on an Al alloy, Zn and bearing metals. Such methods are covered by U. S. patent 1756739, 1870867, 1956466, 1956462, French patents 714180, 785351, English patents 413932, 416371, 428586. Ha (8e)

Defects in Galvanizing (Fehler bei der Verzinkung) Hermann Schörg. *Forschungsarbeiten über Metallkunde und Röntgenmetallographie,* No. 11, 1934, pages 47-50. Briefly describes steel, pickling practice and Zn bath necessary for successful galvanizing. JLG (8e)

Sprayed Stainless Steel Resists Wear and Corrosion Under Trying Conditions. William C. Reid. *Metallizer,* Midsummer, 1936, pages 6, 10. Tests indicate that corrosion resistance of coatings of sprayed stainless steel increases with fineness of finish. Identical results were secured from 90 hour salt spray tests on rolled sheet stainless steel and on polished sprayed coatings. No composition change takes place in spraying stainless steel. BWG (8e)

Unique Applications. D. R. Redding. *Metallizer,* Midsummer, 1936, pages 7-9. Various applications of metal spraying are discussed, including the spraying with mild steel of valve seats for internal combustion motors, coating with stainless steel the face and stems of large valves, and building up gate valve seats with Tobin Bronze. Mild steel was used to fill an inch hole in a marine gas engine cylinder wall. Corrosion on airplanes was prevented by Al spraying exhaust manifold brackets, grab handles, cable thimbles, links on oil control cables, etc. When a bronze monument sent from Italy to Cuba was found to have 150 ft.^{2} of panels missing, a successful substitution was made by building them of concrete, metal spraying with Pb, then with bronze. BWG (8e)

Galvanizing Kettle Heated by Gas-fired Vertical Alloy Tubes. W. H. Spowers, Jr. *Industrial Gas,* Vol. 15, Aug. 1936, pages 9-10. Cr-Ni tubes in which the fuel is burned at the upper end and from which the combustion products leave at the lower end, were the heating units located within the brickwork of the furnace. The dross by this indirect heating of the galvanizing kettle was only a little over 1% in 5 months. Ha (8e)

Machine Element Spraying Technique. Charles Boyden. *Metallizer,* Midsummer 1936, pages 2-4. Various types of machined threads used in preparing material for metallizing are discussed, the chief requirement being a dragging tool to give a ragged thread. New spraying equipment builds the required coating in one pass. This is said to give a denser coating, require less time and eliminate any chance of layer separation. BWG (8e)

Striations in Tin Coatings on Copper. Bruce Chalmers & W. D. Jones. *Metal Industry,* London, Vol. 47, Dec. 27, 1935, pages 627-629, 635. See *Metals & Alloys,* Vol. 7, Aug. 1936, page MA 411L/7. HBG (8e)

The Hot-Tinning of Copper: the Attack on the Basis Metal and its Effect. E. J. Daniels. *Technical Publications, International Tin Research & Development Council,* Series A, No. 33, 1936, 11 pages. Origin of Porosity in the Tin Coating of Tinplate. A. W. Hothersall & J. C. Prytherch. *Iron & Coal Trades Review,* Vol. 132, May 8, 1936, pages 849-852. See *Metals & Alloys,* Vol. 7, Sept. 1936, page MA 455L/5. Ha (8e)

Corrosion After Pickling Major Source of Galvanizer's Dross. Wallace G. Imhoff. *Iron Age,* Vol. 138, Aug. 6, 1936, pages 34-37, 95-97. Last of a series of 3 articles; No. 1 and 2, *Iron Age,* Dec. 5, 1935 and Feb. 20, 1936. Deals with reducing action of molten Zn upon roll scale. Test results show: (1) Corrosion after pickling is major source of Fe to form galvanizer's dross; (2) material not fully pickled must remain in galvanizing bath longer, and bath temperature must be higher to break down oxide scale; and (3) dross crystals were produced, showing that Fe from corrosion is the same Fe that is in dross crystals. VSP (8e)

Cementation of Some Metals by Means of Beryllium Powder. Tsutomu Kase. *Kinzoku no Kenkyu,* Vol. 13, May 1936, pages 173-188. In Japanese. By means of pulverized Be the diffusion of Be into Fe, Ni, and Cu at various temperatures between 600° and 1100° C. was investigated. Hardness determinations, measurement of the depth of penetration, microscopic examination and chemical analysis were carried out on the cemented specimens; also corrosion by some acids and oxidation at high temperatures were studied with the following results: Be diffuses into the metals mentioned at a temperature higher than about 600°, and the rate of diffusion increases with rise of temperature. The rate of diffusion into Fe, however, increases more or less abruptly at the A_3 point (906°). The relation between the weight increase of the specimen (ΔW) or the depth of penetration (P) and the absolute temperature of cementation (T) or the time required for the treatment (Θ) is given by an exponential function ΔW (or P) $= ae^{-b/T}$, where a and b are constants. The cemented surfaces are very much harder than the original materials, and some of them show great resistance to atmospheric oxidation and the attack of certain fused salts at high temperatures. The surface of Fe cemented with Be is not easily attacked by concentrated HNO_3, but, in general, the surfaces of the metals cemented with Be show little increase in resistance to corrosion by strong acids. KT (8e)

8f. Non-Metallic Coatings

Testing Metal Finishes. E. A. Fluevog. *Industrial Finishing,* Vol. 12, May 1936, pages 15-16. Paper before the Midwest regional meeting of Paint & Varnish division, American Chemical Society, describes method of testing metal finishes for adhesion and durability when exposed to severe cold, moisture and bending. VSP (8f)

Tank Painting. C. F. Harris, J. I. Nairne. *Journal American Water Works Association,* Vol. 28, May 1936, pages 640-647. Two separate discussions of tank painting with much practical information. VVK (8f)

The Use of the Microscope in the Porcelain Enameling Industry. E. E. Howe. *Better Enameling,* Vol. 7, June 1936, pages 13-16; July 1936, pages 20-22, 29. Microscope is used to study (a) the structure of cast Fe under blisters in the enamel in search for source of trouble, (b) the bonding material in cast Fe enamels, (c) the bond in sheet Fe ground coat enamels, (d) the effect of steel treatment upon the finished coat, and (e) the causes of such phenomena as copperheads, fishscale, blisters, black spots, and hairlines. Preparation of samples is discussed. CBJ (8f)

Metal Casket Finishes. M. Langius. *Industrial Finishing,* Vol. 12, May 1936, pages 40, 42, 44. Discussion of finishing metal caskets, and their various color combinations. Metal caskets, as received, are covered with a thin film of grease or oil to prevent rusting and are cleaned with steel wool dipped in a cleaning fluid, a cheap grade of thinner. Finishing begins with a thin spray coat of non-sanding lacquer primer. Next a color coat is applied which may be one or a combination of colors. VSP (8f)

Synthetic Bake-enamels for Hospital Furniture. Ray C. Martin. *Industrial Finishing,* Vol. 12, Aug. 1936, pages 44, 46, 62-63. Synthetic enamels for metal hospital furniture are of 2 types: phenol-formaldehyde resins and glycerol-phthalate or alkyd materials. Preliminary cleaning of metal surface is of utmost importance. Coatings of synthetic enamels are easily cleaned and lack odor which is important in hospitals. True value of finishes can be determined by tests in sunlight, moisture, chemicals, etc. VSP (8f)

Porcelain Enameling. William J. Miskella. *Metal Industry,* New York, Vol. 34, Mar. 1936, pages 96-98. Description of the dry and wet processes of enameling together with raw materials, composition of enamels and methods of application. CBJ (8f)

Sparton Automobile Horns. J. B. Nealey. *Industrial Finishing,* Vol. 12, Aug. 1936, pages 22, 24, 26, 28. Describes the mass production of automobile horns including automatic handling of parts, metal cleaning, dipping, and spray- and bake-finishing, cooling and assembling. VSP (8f)

Further Data on Enamel Adherence. Karl Kautz. *Journal American Ceramic Society,* Vol. 15, Apr. 1936, pages 93-108. Review of experimental data obtained by author to test theories of enamel adherence, (1) gripping theory: enamel adheres because it fills over the projections and depressions in metal surface, (2) electrolytic theory: displacement by Fe of Co or Ni in ground coat enamel and adherence by gripping and dendrite formation, (3) dendritic theory: Fe crystallized from solution of Fe oxide in glass "spikes" the enamel to the metal plate, (4) oxide layer theory: intermediate oxide layer between metal and glass provides the bond. Tests are described in which "noble" metal surfaces of Cr, Fe-Cr, stainless steels (15% Cr and 18-8) and surfaces of Fe, Ni and Cu were used for enamel adherence studies. The Fe was tested in vacuo and in atmosphere of N_2 but adherence found to be poor, which thus rules out electrochemical displacement as factor in enamel adherence. Discussion of the constitution of Fe scale is given by a review of literature references. Etched and unetched micrographs are shown of enamels fired on Fe and discussions of mechanics of adherence discussed at length from evidence of the micrographs. Simple gripping or mechanical bonding of ground coat enamel to oxidized metal surface does not exist. For noble metals where no oxidized surface exists the weak adherence found can be explained on basis of simple gripping. No evidence of electrochemical basis for adherence was found nor for dendrite explanation of adherence. It is concluded that adherence is due to a film of ferrous phase about 3" x 10^{-5} thick which is intermediate between the enamel and Fe surface. WB (8f)

Development of Sand Abrasion Machine. G. H. Spencer-Strong. *Journal American Ceramic Society,* Vol. 19, Apr. 1936, pages 112-115. Machine for testing abrasion resistance of enamels by means of sand blast is described and results discussed and shown in tables. WB (8f)

Reviewing Some Pertinent Facts Concerning Aluminum Paint. *Steel,* Vol. 98, June 1, 1936, page 42. Best vehicle is high-bake varnish or synthetic vehicle although good spar varnish will produce a satisfactory finish. For indoor finishes, good grade of clear lacquer should be used. Maximum of 1½ lbs. and minimum of 1¼ lbs. of Al powder per gal. of vehicle should be used. Al pastes have several advantages over dry powder. Although inhibitors have been developed to prevent loss of leafing powder, it is advisable to mix fresh batches daily. Al paints can be tinted to obtain pleasing effects. MS (8f)

"Plicote"—Corrosive Proof Protective Coating. *Industrial Finishing,* Vol. 12, May 1936, pages 56, 58. Describes a new protective paint-like covering for metal, concrete, wood, etc. Contains resin composed principally of rubber hydrocarbon derived from best grade of rubber. It is said to be effective in resisting acids, alkalies, brines, oils and greases. Developed by Watson-Standard Co., Pittsburgh. VSP (8f)

Applying Wet Process Ground Coat Enamels. *Better Enameling,* Vol. 6, Oct. 1935, pages 20-21, 30. Wet process enamel is applied to cast Fe by spraying. Ground coat is applied to sheet metal by dipping and draining or by slushing; large pieces such as sign work may be sprayed. Equipment and control methods are discussed. CBJ (8f)

Spraying Finish Coat Cast Iron Enamel. *Better Enameling,* Vol. 6, Dec. 1935, pages 12-14. Equipment and procedure of applying the finish coat of enamel to cast Fe objects are discussed. CBJ (8f)

Selecting the Sheet Metal and Designing the Product for Enameling. *Better Enameling,* Vol. 6, May 1935, pages 15-19. Enameling difficulties can be avoided by proper selection of sheet metal. Unsuitable metal may lead to copper-heads or dark red-brown spots, blisters, and warping. Selection of proper gage is as important as the quality. Factors in designing the product and forming operations used are described. CBJ (8f)

Cast Iron and Designing Cast Iron Parts for Enameling. *Better Enameling,* Vol. 6, June 1935, pages 15-18, 26. 3 factors which determine the quality of a cast Fe base to be enameled are design of the casting, composition, and foundry practice. In discussing these factors, 4 typical compositions are given. CBJ (8f)

Firing Wet Process Cast Iron Enamel. *Better Enameling,* Vol. 7, Apr. 1936, pages 17-20. Drying, firing practice, and equipment are discussed. CBJ (8f)

Firing Sheet Steel Enamel. *Better Enameling,* Vol. 7, May 1936, pages 21-22, 30. Drying, brushing, firing, and equipment used are described. CBJ (8f)

Thiokol—A New Material Finds Aircraft Uses. *Aero Digest,* Vol. 29, July 1936, pages 29, 110. Synthetic rubber material used for covering metals, etc., has resistance to oil, gasoline, chemicals and oxidizing atmosphere. WB (8f)

The Pylumin Process for the Protection of Aluminium. Pyrene Co. Ltd. *Aluminium & the Non Ferrous Review,* Vol. 1, June 1936, pages 434-436. The process consists in immersing Al for 3-10 minutes in a boiling solution of "Pylumin" powder (composition not stated). The protective coating thereby produced is one to which paints and lacquers adhere firmly. JCC (8f)

The Finishing of Small Objects by the Tumbling Process. *Aluminium & the Non Ferrous Review,* Vol. 1, June 1936, page 443. Small articles may be finished by tumbling in a barrel with the cautious addition of small amounts of lacquer. JCC (8f)

Dip Finishing with Special Equipment. Louis Bodor. *Industrial Finishing,* Vol. 12, June 1936, pages 30, 32. Description of equipment used in finishing various articles by dipping. Important points to consider are: Speed of dipping; angle of dipping; correct dipping fixtures; viscosity of material; and proper drying method. Gives several examples. VSP (8f)

Coloring of Metals. Herbert R. Simonds & C. B. Young. *Iron Age,* Vol. 137, Mar. 26, 1936, pages 48-53; Apr. 16, 1936, pages 25-30; June 18, 1936, pages 30-33, 99. Describes the principal commercial developments in coloring Fe and steel, white metals, Cu and brass, Zn and the cost of metal coloring. Includes results of some recent researches and a description of new method of metal coloring by electrolysis. VSP (8f)

Causes for the Formation of Flakes in Cr-Ni-Mo Steels (Sulle cause della formazione dei fiocchi negli acciai al cromo-nickel-molibdeno) I. MUSATTI & A. REGGIORI. *La Metallurgia Italiana,* Vol. 28, May 1936, pages 197-218. See *Metals & Alloys,* Vol. 7, Apr. 1936, page MA 197L/5. AWC (9a)

Magnaflux Inspection Methods in Airplane Engines. H. J. NOBLE. *Metals & Alloys,* Vol. 7, July 1936, pages 167-170. Describes method of locating defects in magnetized steel or its alloys by means of a finely divided paramagnetic material. The material may be dusted on the magnetized piece under test or the piece immersed in a kerosene suspension of the material. Defects discoverable and application of method to airplane parts are discussed. WLC (9a)

X-rays and Arc Welding (Les Rayons X et la Soudure à l'Arc) F. GRÉBERT. *Arts-et-Métiers,* Vol. 89, May 1936, pages 107-110. Explains the stereoscopic method for determining position and size of inside defects and gives typical examples of defects: blow-holes, slag inclusions, cracks. FR (9a)

Failure of Locomotive Parts. F. H. WILLIAMS. *Railway Mechanical Engineer,* Vol. 110, May 1936, pages 190-192; June 1936, pages 249-251. Incorrect shape, sharp corners and poor machining are often found to be the cause of failures of side-rods. Examples are described in illustration. Ha (9a)

New Advances in X-ray Diffraction Applications in Chemical Plants (Neue Fortschritte der Feinstrukturuntersuchung durch Röntgenröhren in ihrer Bedeutung für den Bau chemischer Apparate) A. KARSTEN. *Chemische Apparatur,* Vol. 23, May 1936, page 26. Description of new portable instruments of small size and high efficiency, fully safeguarded against high tension and radiation. Their application for the detection of corrosion, wear, and recrystallization of materials is discussed. HR (9a)

Heat Treated Bridge Wire Failures Reproduced in Tests. *Engineering News-Record,* Vol. 117, Aug. 13, 1936, pages 217-221. Investigation by the Bureau of Standards of wire removed from Mt. Hope bridge indicates inability of crystalline micro-structure to resist fatigue fracture under fluctuating tensile loads as the cause of failure. CBJ (9a)

Bridge Wire Tests Leave Some Questions Unanswered. E. E. THUM. *Engineering News-Record,* Vol. 117, Aug. 13, 1936, pages 221-223. Bureau of Standards Report on bridge wire failure is analyzed. Author suggests further study necessary. CBJ (9a)

Detecting Defects in Ferromagnetic Materials by the Use of Filings (Fehlernachweis in ferromagnetischen Werkstoffen nach dem Feilspäneverfahren) JOHANNES KRAUSE. *Forschungsarbeiten über Metallkunde und Röntgenmetallographie,* No. 16, 1935, 54 pages. Describes experiments to determine the suitability of Fe powder held in suspension and applied to a magnetized part for determining defects. The method is not very suitable for parts of very irregular section and for heavy parts. It is very successful in locating defects in small parts of not too irregular section. In heavy parts small defects near the surface are shown while much larger defects near the core are not shown. Results obtained with welds are difficult to interpret. The method is suitable for detecting defects in semi-finished parts such as bolts prior to threading and for locating hardening cracks. JLG (9a)

Methods for Determining the Thickness of Zinc Coatings. WALTER R. MEYER. *Metal Industry,* New York, Vol. 34, May 1936, pages 173-175. The Hull-Strausser drop test, Sb chloride-HCl strip measurement, microscopic measurement, and analytical measurements give reliable and correlated results when used on electrogalvanized Zn coatings. The Preece test has too large a percentage error for measurement of deposits less than 0.001″ thick. The stripping-analytical method is most reliable for determining the weight of Zn in sherardized coatings. The Preece test gives very unreliable results for sherardized coatings. The most reliable method for determining the amount of Zn in hot-galvanized coatings is the stripping-analytical method. The accuracy of the Preece test, microscopic measurement, and the Sb chloride-HCl strip test varies with the ratio of alloyed Zn to free Zn. The Preece test and microscopic measurement are valuable in determining the distribution of the Zn coatings. CBJ (9a)

NEW ELECTRONIC RECORDER

A modern achievement in the field of materials testing.

Developed and manufactured by Tinius Olsen this new Electric Elongation Recorder was exhibited and demonstrated at the National Power Show in New York City.

No mechanical connections from the extensometer, all records are made electrically.

Magnification ranges of 250, 500 and 1000 times.

Can be used on rounds or flats in tension and in connection with a compressometer for compression testing.

Speed of operation; curves taken in 30 seconds.

Shifting from one range to any other accomplished in a remarkably short period.

Drop in and see this new control apparatus developed for your convenience.

Torsion Measuring Apparatus Bamag (Le torsiomètre Bamag) ANDRÉ TENOT. *Génie Civil,* Vol. 108, Feb. 8, 1936, pages 141-142. Mechanics of the apparatus containing stroboscopic features are described. JDG (9b)

A Research into Tests for Materials used in Cold Pressing Operations, with Special Reference to the Fluid-pressure Cupping Test. H. J. GOUGH & G. A. HANKINS. *Journal Royal Aeronautical Society,* Vol. 39, Nov. 1935, pages 1047-1075; discussion page 1092. Paper read at a joint meeting of the Royal Aeronautical Society, the Institution of Automobile Engineers and other groups. Some of the mechanical tests often employed for sheet metal are examined critically, with particular attention to the investigation and development of a new form of cupping test. Materials for cold-pressing operations can not be qualified by a simple test owing to the plastic rather than the elastic nature of such operations. Strain hardening following plastic deformation is also difficult to allow for, owing to the time element in the recovery, wholly or partly, of elasticity. Attempts to specify suitable material are based on combinations of tensile strength, chemical composition, and microstructure data. The cupping tests in use serve to distinguish absolutely unsuitable materials from the rest, but are unable to grade as fair or perfect those that pass the test. The outstanding deficiency of the usual cupping test is the use of a distending tool. In the cupping test developed by the author deformation is accomplished by applying fluid pressure to one side of the sheet, forming the latter into a dome. Results with the new test are compared with those obtained by the usual cupping tests and with tensile strength data for a large number of standard and miscellaneous sheet materials. FPP (9b)

Notch-Impact Toughness (Zur Frage der Kerbschlagzähigkeit) M. MOSER. *Zwanglose Mitteilungen des deutschen und oesterreichischen Verbandes für die Materialprüfungen der Technik,* No. 28, May 1936, pages 412-413. A discussion on current practice and the suitability of the Charpy test. No change in present rules seems desirable. Ha (9b)

Testing Cast Iron Using Cylindrical Test Pieces 5.64 mm. Diameter (L'essai des fontes sur l'eprouvette cylindrique de 5.64 mm de diametre). PIERRE NICOLAU. *Revue de Métallurgie,* Vol. 33, May 1936, pages 348-352; June 1936, pages 393-399. Recommends testing properties of cast Fe using a test piece 5.64 mm. diameter. Gives description of F. Eugene machine for testing hardness, shear strength, compression and bending on these specimens as well as of an apparatus proposed by the author for alternating impact testing. JDG (9b)

9c. Fatigue Testing

H. F. MOORE, SECTION EDITOR

The abstracts appearing under this heading are prepared in cooperation with the A.S.T.M. Research Committee on Fatigue of Metals. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

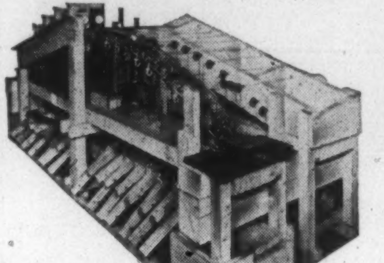
Endurance and Damping of Commercial Steels and Copper and the Effect of Cold Riveting (Die Schwingungsfestigkeit und Dämpfungsfähigkeit von handelsüblichen Stählen und Kupfer und ihre Beeinflussung durch Kaltnietung). *Mitteilungen des Wöhler Instituts,* Heft 28, 1936, 87 pages. This work was carried on upon Armco Fe and 3 commercial grades of steel classed under German specifications as Nos. 34, 37 and 50, i.e., of 48,500, 52,500 and 71,000 lbs./in.^{2} minimum tensile strength. Different lots of No. 37 were used, ranging from 0.05 to 0.12% C and from 54,000 tensile 30% elongation to 63,000, 22%, in different gages. Under similar test conditions the damping power of the different lots varied as much as 8 to 10 times. The author does not relate these differences to finishing temperatures in rolling or to degree of reduction. With such variations in materials tested, generalizations from his data would be difficult to draw; and instead he describes each particular test in great detail. Part of the work is an extension of the studies of Appenrodt (Heft 24) on damping at room temperature and at 120° C., in which the endurance limit of specimens of the material under test is estimated by running 2 million cycles, raising the stress 10%, running another 2 million, and so on, from which an approximate endurance limit for material thus strengthened by understressing, is estimated. The damping tests are then made at a load of 25% under, for room temperature and 30% under, for 120° C. the estimated endurance limits. The damping curves are taken as received, after 50,000, ¼ million, 1¼ million, 6¼ million and 31¼ million cycles. At room temperature the various steels increase in damping power to a maximum somewhere around 1¼ to 6¼ million and then decrease, but do not come clear back to the starting point, while at 120° C. the damping increases all the time. Cu was not studied in this phase of the work. Endurance and damping tests were made on solid specimens of Cu, Armco and No. 34 steel, and on other specimens made by riveting together two pieces of stock each half the thickness of the solid specimen being compared. As would be expected, the endurance limits of the riveted assemblies were lower and the damping higher than in the solid specimens, and the result showed considerable scatter. Fatigue failure did not always start at a rivet hole, but sometimes at the edge of a rivet head, or at a point in the interior of the riveted assembly where the 2 halves rubbed together. Photos of the fractures are shown. HWG (9c)

Leadership
in TESTING
methods and equipment

●

In the movement towards weight reduction in vehicles and toward the study of stress distribution in pressure vessels, reinforced concrete arches, suspension bridges, etc.—strain gauging of structures has contributed greatly.

The analysis by models prior to the construction of the main structure, and tests to destruction of a full sized structure scheduled for abandonment have been employed to aid these studies.



● In Model Studies

Professor Beggs of Princeton has done much, his work including models of the towers of the Golden Gate Bridge constructed to exact scale in stainless steel; and a model of the world's largest floating drydock.

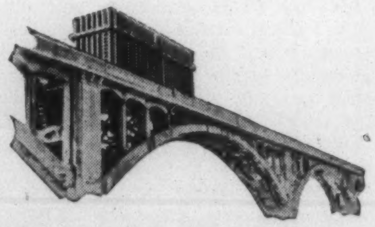
The Aluminum Company of America and the Bureau of Reclamation have studied models of dams, prior to actual construction followed by comparisons with the prototype.

Professor Large at Ohio State College has made studies of a skyscraper model. The U. S. Experimental Model Basin uses ship models for study. The Port of New York authority have studied models of the George Washington and Bayonne Bridges.

Other bridge structures such as the San Francisco-Oakland Bay Bridge have been studied in models.

Models have been made in celluloid, rubber compound, wires, stainless steel sheet—and the stress analysis made with dial gauges and very notably with Huggenberger Extensometers. (See illustration.)

Professor Beggs has attacked model studies from another angle—with the use of the Deformeter Gauges, wherein celluloid models are studied in two dimensions by introducing known deformations instead of loads, utilizing Maxwell's theorem and reading deflections with microscopes. Among many such uses was the study of the overhead system during the electrification of the Illinois Central Railroad at Chicago.



● Full Scale Tests

to destruction, or planned destruction, have been made on such structures as the Stevenson Creek Arch Dam and the Yadkin River Bridge. This latter was a full sized highway bridge. On these structures, the Electric Telemeter was used and in the dam test the Whittemore Strain Gauge came into use—a gauge in which the best reproducibility of readings was obtained.

The use of the Whittemore Strain Gauge has spread rapidly for stress analysis in the field. It was used on the Sidney Harbor Bridge by Dr. Bradfield, and is in use for such similar work as done by the American Bridge Company. It is used for arch tests, such as were conducted at the University of Illinois and Lehigh University, and in most of the major analyses of recent years.

Likewise, the rapid developments in aviation, automotive and railway equipment have advanced to an important place, the use of the Huggenberger Extensometer, the Scratch Recorder (for dynamic as well as static measurement), the Whittemore Strain Gauge and the electric recording instruments for stress studies, both under static loading and in reproductions of service conditions in live loading.

The Rate of Growth of Fatigue Cracks. A. V. de Forest. *Journal of Applied Mechanics,* Vol. 3, Mar. 1936, pages A23-A25. The resistance of metals to the propagation of cracks is discussed; it is found that the usual fatigue test results are not conclusive if no distinction is made between repeated stresses required to start cracks and stresses to propagate the cracks to failure. 2 items are important: (1) stress and cycles required to start a fatigue crack and (2) stress and cycles required to propagate the crack to failure. The first is greatly affected by surface conditions while the second is dependent on the metallurgical condition of the metal. (Note by H. F. M.: Fatigue tests on car axle steel and rail steel indicate that the stress necessary to propagate a crack may be as low as 50% of the stress necessary to start it.) 5 references. Ha (9c)

Fatigue Properties of Nitrided Steel. H. Sutton. *Metal Treatment,* Vol. 2, Summer 1936, pages 89-92. Wöhler tests made on nitrided test pieces and on specimens cut from the core of a larger nitrided bar of the same nitralloy steel confirmed earlier conclusions that nitriding produces an increase of 20-40% in the fatigue limit under reversed bending. Tests in a Haigh machine, however, showed that no appreciable improvement was produced under reversed direct stresses. In the Wöhler tests, failure commences at a point near the junction of case and core; and in these conditions surface defects and notches have, as might be expected, little influence on the fatigue strength. (Note by H. F. M.: The different behavior in the cases of flexure tests and tension tests may be explained by the fact that in flexure tests the nitrided metal at the surface is in a position to resist the highest bending stress; in the tension tests all the cross section is subjected to equal stress and nitriding is less effective as a stress raiser.) JCC (9c)

Two- and Three-Dimensional Cases of Stress Concentration, and Comparison with Fatigue Tests. R. E. Peterson & A. M. Wahl. *Journal of Applied Mechanics,* Vol. 3, Mar. 1936, pages A15-A22. A determination of stress-concentration factors shows that in some cases practical fatigue results are quite close to theoretical values, and that fatigue results for alloy steels and quenched C steels are usually closer to theoretical values than are the corresponding fatigue results for unquenched C steels. The size of the specimen has some influence on the test results, sensitivity factors from small specimens should not be applied indiscriminately to machine parts. 18 references. Ha (9c)

Study of Fatigue Strength of Welds (Etude de la résistance à la fatigue des soudures à franc-bord) H. D. Dutilleul. *Génie Civil,* Vol. 108, Jan. 11, 1936, pages 62-64. Fatigue testing machine is described in which sockets are provided on both ends of the shaft of a high speed motor into which tapered test specimens are screwed. The latter are loaded on cantilever principle by weights supported by roller bearings. Properties of some welds were determined on specimens prepared from samples cut across the bead. JDG (9c)

Internal Stresses and Fatigue Resistance of Spring Steels. M. L. Becker & C. E. Phillips. *Iron & Coal Trades Review,* Vol. 132, May 8, 1936, pages 846-849; *Heat Treating & Forging,* Vol. 22, May 1936, pages 227-232, 240. See *Metals & Alloys,* Vol. 7, Aug. 1936, page MA 412R/4. Ha + MS (9c)

Further Experiments on the Effect of Surface Conditions on the Fatigue Resistance of Steels. G. A. Hankins, M. L. Becker & H. R. Mills. *Iron & Steel Institute,* Advance Copy No. 8, May 1936, 27 pages. The investigation was carried out as a continuation of work on fatigue resistance of unmachined steels. Results of fatigue tests on 2 steels are reported, the work being done to determine the influence of decarburization and surface irregularity both together and singly. An attempt was made to improve fatigue resistance of such steels by recarburization. Tests were made on unmachined steel forgings having a tensile strength in excess of 224,000 lb./in.^{2} Some results are given on fatigue tests of unmachined mild steels. It is concluded that the combination of surface irregularities or inclusions and decarburization is the major cause of the low fatigue resistance of unmachined spring steels. Surface recarburization of decarburized steels was found to increase fatigue resistance in some cases, but such treatment is not recommended in commercial operations. The effect of unmachined surface on very high tensile forgings is very marked, the endurance limit being less than half that for machined steel. It is concluded that the effect of unmachined surface on the fatigue strength of mild steel is not important, although exceptions may occur. JLG (9c)

■ 9d. Magnetic Testing ■

The Ferromagnetism of Nickel. I, II. Temperature Effects. J. C. Slater. *Physical Review,* Vol. 49, Apr. 1936, pages 537-545; June 1936, pages 931-937. By using metallic energy levels extrapolated from Cu to Ni, the energy difference between a nonmagnetic and a ferromagnetic state with permanent magnetic moment is calculated for Ni, and it is shown that the ferromagnetic state is the stable one. Both saturation magnetic moment and Curie point are calculated, in agreement with experiment within the limits of error of the calculation. Extrapolation further into the Fe group, though less justified than to Ni, indicates that ferromagnetism should persist in that group down approximately to Fe. The criterion for ferromagnetism previously suggested by the author, the existence of inner unfilled electron shells (the 3d), small in proportion to their distance apart, is justified. The calculation is not made according to Heisenberg's method, which is considered to be unsuitable for application to ferromagnetism, except in its general principle of explaining the energy of orientation of elementary magnets in terms of exchange energy. Part II. The temperature variation of the ferromagnetism of Ni is discussed. The free energy is computed as a function of temperature and magnetic moment. At each temperature, the value of magnetic moment for which the free energy is a minimum is the value which will actually be found, and this decreases with increasing temperature, going to zero at the Curie point, in satisfactory agreement with experiment. The value of the free energy itself at the minimum, as a function of temperature, is compared with experimental values derived from the observed electronic specific of Ni, and the agreement is again satisfactory. It is found that even at the absolute zero not quite all of the spins are parallel to each other, the minimum in the free energy curve coming at a little less than the maximum possible magnetic moment. It is suggested that this small effect becomes much more pronounced as Fe is approached in the series of ferromagnetic elements, explaining the fact that alloys of Fe and Co show the highest saturation moments of any ferromagnetic substances, the moment then decreasing in Fe and even more in alloys of Fe with lighter elements. ■ 9e. Spectrography ■

L. W. STROCK, SECTION EDITOR

Electronic Microscope (Le Microscope électronique) J. R. Maréchal. *Revue Universelle des Mines,* Vol. 12, Aug. 1936, pages 325-330. Theory of the electron microscope and the high separation power which it has attained now by the use of monochromatic ultraviolet light and objectives of naphthalene monobromide, is explained and examples of structures obtained with it shown in photographs. 14 references. Ha (9e)

Quantitative Spectroscopic Determination of Antimony in Copper (Quantitative Spektralanalytische Bestimmung von Antimon in Kupfer) B. A. Lomakin & A. L. Ostaschewskaja. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 228, July 14, 1936, pages 44-48. WB (9e)

New X-Ray Spectroscopic Method for the Chemical Analysis of Polished Sections (Eine neue röntgenspektroskopische Methode zur chemischen Analyse von Anschliffen) L. v. Hamos. *Metallwirtschaft,* Vol. 15, May 8, 1936, pages 433-436. A plane surface of the specimen to be analyzed is exposed to primary X-rays, whose reflections are screened from the film. The secondary X-rays emitted from the specimen are diffracted from a bent crystal onto the film. Since the wave length of these secondary rays is characteristic of the material, the positions of spots on the film show the chemical components of the specimen. The fine structure and intensity of any individual film spot shows the distribution of that particular element in the portion of the sample exposed. Typical photographs are shown. GD (9e)

Isotopic Constitution of Lead from Hyperfine Structure. John L. Rose & R. K. Stranathan. *Physical Review,* Vol. 49, June 1936, pages 916-920. The relative abundance of the isotopes of Pb was determined from intensity measurements of the hyperfine structure components of the Pb spark line λ5372. With 11 calibrated wire screens a single order of the Fabry-Perot interference pattern was photographed with the same exposure time for each screen. The following results from densitometer measurements were obtained for the percentage abundance of the isotopes of ordinary Pb: 51.5, 26.3, 21.4, and 0.8 for Pb^{208}, Pb^{206}, Pb^{207}, and Pb^{204}, respectively. For integral masses of the isotopes the mean mass number is 207.22_8. Assuming a packing factor of +1, this number when converted to the chemical atomic weight scale becomes 207.20. WAT (9e)

The Strength of Metals under Combined Alternating Stresses. H. J. Gough & H. V. Pollard. *Proceedings Institution of Mechanical Engineers,* Vol. 131, Oct.-Dec. 1935, pages 3-103. Includes discussion. See *Metals & Alloys,* Vol. 7, Jan. 1936, page MA 25R/2. Ha (9e)

Analysis of Materials by the X-ray Diffraction Method. H. R. Isenburger. *Product Engineering,* Vol. 7, May 1936, pages 177-179; July 1936, pages 264-266. Elementary. Ha (10)

An Electron Microscope for Filaments: Emission and Adsorption by Tungsten Single Crystals. R. P. Johnson & W. Shockley. *Physical Review,* Vol. 49, Mar. 1936, pages 436-440. A new and simple electron microscope has been designed for small cylindrical filaments. Die marks are found to be prominent in the electron images of all drawn wires. The activation of thoriated W has been studied. Electron emission from single crystals grown in drawn pure W filaments varies around the wire circumference and depends systematically on crystallographic direction. This variation of emission with crystallographic direction is more pronounced and complex when the filament is allowed to self-activate in Cs or K vapor. WAT (10)

A Novelty in the Field of Material Testing and Its Importance in Foundry Practice (Eine Neuerung auf dem Gebiete werkstoffkundlicher Prüfverfahren und ihre Bedeutung in der Giessereipraxis). A. Karsten. *Giesserei,* Vol. 23, May 22, 1936, pages 265-268. New microphotographic instruments are described. Ha (10)

Isothermal Transformation of Austenite. S. A. Kazeev. *Metallurg,* Vol. 11, June 1936, pages 43-54. In Russian. Amount of austenite which decomposes during interval *t* is equal to $A = 100e^{-at^{n}}$, expressed in percentage. This expression corresponds to a straight line in logarithmic coordinates. Data obtained by F. Wever & W. Jellinghaus (*Mitteilungen aus dem Kaiser-Wilhelm-Institut für Eisenforschung,* Vol. 13, 1933) closely arrange themselves along these straight lines, the equation becoming $A = 100e^{-0.001555t^{2.475}}$. It remains valid when decomposition forms only cementite and ferrite. When it results in martensite, the straight line has a break in it; for 185° C. and 0.89% C steel, it occurs at 120 minutes. During the first 120 minutes the reaction proceeds according to $A = 100e^{-0.00334t^{1.008}}$ and after this period according to $A = 100e^{-0.0956t^{0.808}}$. Process of decomposition in 2 stages does not always take place continuously. The second stage begins sometimes only after a certain lapse of time during which transformation either does not occur at all or proceeds slowly. As a rule, this situation is observed on undercooled austenites, the lower the temperature the more austenite is decomposed during the first stage and less during the second. Austenite decomposition rate continuously changes during the process and can be represented by the following derivative of the above equation: $v_{max} = 100k^{k}a^{1-k}n\,e^{-k}$. Applied to 1.07%C, 1.52 Cr and to 0.95% C steels the above formula indicates that the maximum transformation rate corresponds to a moment at which austenite content is 55-60%. Time required for complete decomposition is about 2.5 times as long as is necessary to reach the maximum transformation speed; *i.e.,* the average transformation rate before reaching the maximum is greater than after it. Time required to produce a 99% decomposition can be expressed by $t_n = \sqrt[n]{\frac{4.6051}{a}}$, so that for the half decomposition often mentioned in literature it will be $t_{50} = \sqrt[n]{\frac{0.693}{a}}$. Plotting C content against maximum transformation speed of austenite in %/sec. showed that C stabilizes austenite. Data obtained by Davenport and Bain for a 1.17% C steel were used for determination of maximum transformation speed as a function of quenching temperature. The curve consists of 2 straight lines intersecting at an angle corresponding to 955° C. Raising temperature from 843° to 955° C. pronouncedly stabilizes austenite, but above this range the influence of temperature is much less efficient. At 955° C. all cementite is in solution and further heating might only cause some local concentration of the element. Heating under 955° C. is 18 times more efficient for stabilization than above it. The curves used for calculations were given by the above authors to demonstrate stability of austenite as a function of grain size, but calculations show that they fail to do so because grain size is a continuous function of temperature, and intersection at 955° C. could not occur were the curves to represent grain size alone. With considerable undercooling austenite transforms in 2 stages, the first of which is more intense than the second. The classical S-curve in its lower part is a function of cooling conditions used in experimentation, with variations of which the corresponding portion of the curve will change also. The first stage is induced by internal strains in the metal. When they are reduced by slipping to a greater or lesser extent, further transformations of austenite take place in the regular order. (10)

On "Somatoid" Elements of Structure in Electrolytic Metal Deposits. V. Kohlschütter. *Transactions Faraday Society,* Vol. 31, Sept. 1935, pages 1181-1188. Discussion on page 1218. "Somatoids" are small independent particles, mostly of crystalline structure, which possess characteristic shape, but which are essentially different from true perfect, or only partly developed crystals. The internal structure of "somatoid" is not homogeneous but the material is distributed in them in a characteristic fashion which determines their outward appearance. "Somatoids" are almost always products of a compound action of crystallization forces with surface forces forming mobile masses. Spherical drops and normal shaped crystals are the two extremes. The mechanism of the formation of "somatoids" in electrolytic deposition is discussed at length. 6 references. PRK (10)

Unequaled Versatility

● ● ● *an outstanding feature of the Leitz Panphot which although but recently announced has already attained wide acceptance and is gaining new adherents daily.*

The Leitz Panphot answers the need for a single instrument that can handle the ever increasing complexities of microscopical research problems. It's the most useful and versatile instrument with which the metallurgist's laboratory can be equipped.

Equally convenient for visual observation and photomicrography, it makes use of all of the following methods of illumination:

Transmitted Light
polarized or non-polarized
Darkfield
in transmitted light

Reflected Light
polarized or non-polarized
Darkfield
in reflected light (Ultropak)

These are but a few of its many useful features. They are fully described in Catalogue No. 7552. Shall we send you a copy?

BERYLLIUM

Its Production and Application

By Zentralstelle fuer wissenschaftlich-technische Forschungsarbeiten des Siemens-Konzern

Translated by RICHARD RIMBACH *and* A. J. MICHEL

NOT only is this the first thorough treatise on beryllium to appear in English, which fact alone makes it welcome to American metallurgical engineering, but it presents in concise and usable form what might be termed "all about" this coming metal. The authoritativeness of this book arises from the fact that it is essentially an account of ten years' work on beryllium and its alloys by the very men who systematically conducted these researches, augmented by reports contributed by other workers in this field. This book will be found indispensable not only to workers in the more obvious field of light-metal alloys, but equally to those interested in the alloys of the heavier metals.

CHAPTERS

Introduction.
Outline of the Research Program on the Production and Uses of Beryllium.
The Analytical Chemistry of Beryllium.
The Occurrence of Beryllium.
The Thermal Reduction of Beryllium.
Investigation on the Dressing of Raw Beryl and on the Production of Beryllium Salts Suitable for Electrolysis.
Electrolytic Production of Beryllium.
The Influence of Bath Composition and Bath Temperature on the Stock-Goldschmidt Siemens & Halske Method for the Production of Beryllium.
Physical and Chemical Properties of Beryllium.
The Production of Electrolytic Deposits of Beryllium by High Temperature Electrolysis.
Direct Electrolytic Production of Beryllium Alloys.
The Structure of Beryllium-Copper Alloys.
Physical Properties and Age Hardening of Beryllium Copper Alloys.
Changes in the Electrical Conductivity and the Volume During the Age Hardening Beryllium-Copper Alloys.
The Changes in the Modulus of Elasticity During the Age Hardening Beryllium-Copper Alloys.
Changes in the Microstructure of Beryllium-Copper Alloys Due to Age Hardening.
X-Ray Investigation of the Age Hardening Process in Beryllium-Copper Alloys.
Theory of the Age Hardening Process Based on the Investigation of Beryllium-Copper Alloys.
The Effect of Small Additions of Phosphorus on the Age Hardening of Beryllium-Copper Alloys.
Ternary Copper-Base Alloys Containing Beryllium.
Beryllium-Nickel Alloys.
Beryllium-Iron Alloys.
Magnetic Measurements of Iron-Beryllium Alloys.
Aluminum Beryllium Alloys with an Appendix on Silicon-Beryllium Alloys.

1 **Primary Crystallization of Metals.** F. R. HENSEL. *Blast Furnace & Steel Plant,* Vol. 24, Feb. 1936, pages 145-148; Mar. 1936, pages 231-234. Paper read before the Detroit Foundrymen's Association, Oct. 17, 1935. After discussing theories adopted for explaining ingot structure, and listing metallurgical factors affecting primary structure, describes investigation of primary crystallization during solidification. MS (10)

2 **Relation of Mechanical Properties of Cast Iron to Structure (Ueber den Zusammenhang der mechanischen Eigenschaften des Gusseisens mit der Gefügeform)** G. MEYERSBERG. *Giesserei,* Vol. 23, June 5, 1936, pages 285-290; June 19, 1936, pages 315-320. Mechanics of fracture of cast Fe is discussed and the difference between that of steel and of cast Fe explained; in the latter, not the tensile strength, but the separating strength determines the fracture. The graphite inclusions exert a certain reducing effect, which determines the character of the fracture in cast Fe; this "contraction factor" is defined as $e = E_s/E_c$, where E = the elastic modulus and the indices s and c designate steel and cast Fe. The higher e, the more the tensile strength is reduced. In a similar manner also the notch effect of graphite inclusions and distribution is taken into account. A 3-dimensional diagram gives the numerical values for relations between tensile strength, separating strength, and contraction factor. 12 references. Ha (10)

3 **On the Mechanism of Transformation of Face Centered Cubic into Hexagonal Close-packed Lattice.** ZENJI NISHIYAMA. *Science Reports Tohoku Imperial University,* Vol. 25, Apr. 1936, pages 79-93. This transformation was studied with an alloy of 70 Co-30 Ni. Repeated treatments of heating at 500° C. for an hour and cooling in liquid N were given. Aside from determining the crystallographic relations it was established that one γ crystal can give rise to 4 differently oriented *h* crystals, which, by reverse transformation, are brought back to γ crystals of the original orientation. BWG (10)

4 **Transformation Gamma⟶Alpha of Stainless Invar Caused by Stress, and the Mechanism of the Transformation.** ZENJI NISHIYAMA. *Science Reports Tohoku Imperial University,* Vol. 25, Apr. 1936, pages 94-103. Transformation by stress was found by X-ray analysis to take place by the same mechanism as in the transformation by temperature change. Transformation started with a tensile stress of 20 kg./mm.^{2}, the yield point. Change took place first on the surface then proceeded inwardly. BWG (10)

Grain Size in Metals. M. G. OKNOV. *Metallurg,* Vol. 11, Mar. 1936, pages 3-8. In Russian. Grain size of Zn (0.03 Fe, 0.015 Cd, 0.009 Pb, Sb, Sn, Al none) was studied by adding to molten Zn small amounts of different elements. No conclusive results were reached, though several interesting theories are proposed. (10)

5 **Vanadium and Zirconium as Ternary Constituents in Al Bronzes (Il vanadio e lo zirconio come costituenti ternari nei bronzi d'alluminio)** C. PANSERI. *Alluminio,* Vol. 5, Mar.-Apr. 1936, pages 37-45. The effect of additions of V and Zr to 90-10 Al bronze has been studied. As little as 0.24% V has a refining action on the microstructure. The macrostructure, however, is coarsened. Zr also tends to give a finer microstructure, but its action is much less marked. AWC (10)

6 **X-Ray Investigation of the Iron-chromium-silicon Phase Diagram.** A. G. H. ANDERSEN & ERIC R. JETTE. *Transactions American Society for Metals* Vol. 24, June 1936, pages 375-419. Crystal studies by X-rays are reported for Fe-rich Fe-Cr-Si alloys. Interpolation and extrapolation based upon orthographic projection have been applied to determination of surfaces which represent variation of lattice parameter with composition in 1- and 2-phase regions. These parametric surfaces have been developed with considerable accuracy. α phase is homogeneous from 0-35% Cr at 600°, 800°, 1000° C. and is bounded by 3 surfaces. First is equilibrium with $(Fe, Cr)_3Si_2$, which is isomorphic with Fe_3Si_2; second and shortest is equilibrium with a phase isomorphic with Cr_3Si; third and largest is equilibrium with FeCr, which is found to exist over a wide range. This phase (σ) dissolves up to 9 or 10% of Si. σ forms by precipitation from binary and ternary α solid solution. α boundary in this region changes rapidly with temperature; thus precipitation hardening is possible over a wide range of composition. Diagrams cover the system below 50 at. % or 33% by wt. of Si. WLC (10)

7

8 **A Contribution to the Knowledge of Magnetic Anisotropy of Polycrystalline Materials (Ein Beitrag zur Kenntnis der magnetischen Anisotropie vielkristalliner Werkstoffe)** O. VON AUWERS. *Wissenschaftliche Veröffentlichungen aus den Siemens-Werken,* Vol. 15, May 1936, pages 112-123. Endeavors in recent years to produce materials with definite ferromagnetic properties and to influence the shape of the hysteresis loop are discussed, and the involved theory and the reason for magnetic anisotropy in the crystal axes of the material are explained. Means for producing magnetic irregularities by external forces, tension or compression, or internal forces by influencing the crystal lattice in polycrystalline commercial materials, are discussed on the basis of knowledge gained on monocrystals, and experiments are described which illustrate the practical application of theoretical principles to an Fe-Ni alloy. 37 references. Ha (10)

9 **Austenitic Grain Size: Estimation and Significance.** EDGAR C. BAIN. *Steel,* Vol. 98, May 11, 1936, page 66: Abstract of paper before interchapter meeting of American Society for Metals at Pennsylvania State College, May 1-2. Fine austenite grains, upon transforming, yield tougher heat treated structures than do coarser grains; tendency to crack is less; and critical quenching speed for hardening is higher for some composition having finer grains. Size of grains of austenite is determined from structure resulting from its decomposition. Polished and etched specimen will reveal grains by virtue of contrast in appearance between network and grain bodies. Suitably etched martensite faithfully reveals size of parent austenite grains from which it formed by difference in darkening of the several orientations. MS (10)

10 **Absorption of Soft X-rays in Aluminium.** G. B. BANDOPADHYAYA & A. T. MAITRA. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Vol. 21, May 1936, pages 869-880. The mass absorption coefficients were determined accurately for wave lengths from 7 to 25 A.U. The general absorption curves by Jönsson and Stobbe were found not to give accurate results due to the fact that in the soft X-ray region the part played by electrons close to the optical levels becomes appreciable and that therefore the simple laws holding good in the ordinary X-ray region for electrons in the deeper levels begin to become complicated. 20 references. Ha (10)

Factors Affecting the Structure and Properties of Gray Cast Iron. A. Di Giulio & A. E. White. *Transactions American Foundrymen's Association,* Vol. 7, June 1936, pages 531-565. The effect of superheating cast Fe of the unalloyed automotive-cylinder type (T. C. 3.36%; G. C. 2.76%; Si 2.00%; S 0.118%; P 0.36%; Mn 0.48%; O 0.012%; H 0.00015%; and N 0.0045%) was investigated by heating the metal to 3110° F. The beneficial effects of superheating were apparent at temperatures in the neighborhood of 2700° F. and increased with temperature up to a maximum at about 3040° F. The effect of pouring temperature on various cast irons was also investigated. An optimum range for pouring was established between 2680° and 2850° F. Better physical properties obtained through superheating and by pouring at the proper temperature are ascribed to a refinement of the graphite flakes. Specifically, the improvement in physical properties is due to the fact that, under proper conditions of melting and casting, the graphite flakes of the material of the charge are entirely dissolved. Evidence is furnished which proves that graphite will not all pass into solution at the eutectic temperature, but will persist as such in the melt, as revealed by quenching molten cast Fe in water. CMS (10)

Equilibrium in the Reaction of Hydrogen with Ferrous Oxide in Liquid Iron at 1600 Degrees Cent. M. G. Fontana & John Chipman. *Transactions American Society for Metals,* Vol. 24, June 1936, pages 313-336. Experimental study of the equilibrium of the reduction of dissolved FeO by H_2 at 1600° C. leads to the following conclusions. The equilibrium constant is independent of O_2 concentration. Activity of FeO in liquid Fe is proportional to its wt.%. Error in previous work is shown by correction of the constant from 4.75 to 3.95. Free energy of formation of FeO in 1% solution in liquid Fe determined as—34,740 cal. at 1600° C. (2910° F.). Value of C-Fe oxide product at equilibrium in liquid Fe calculated as 0.006 confirms experimental value of 0.010. Value of the constant of the water gas reaction found by using present data and that of Vacher agrees with other sources. 14 references. WLC (10)

Distribution of Hypereutectoid Cementite in Cemented Ni-Cr-Mo Steels (La distribuzione della cementite ipereutettoide negli acciai al Ni-Cr-Mo cementati) A. Bartocci. *La Metallurgia Italiana,* Vol. 28, Mar. 1936, pages 101-111. Presence of special elements causes displacement of the eutectoid point. The effect of cementation at 900°-1000° C. on a steel of the type 0.30% C, 3.5% Ni, 0.80% Cr, and 0.50% Mo has been studied. High temperature favors the formation of a continuous cementite network bordering the austenitic crystals, although part is trapped within. Rapid cooling after cementation increases the proportion trapped so that on very rapid cooling all the hypereutectoid cementite remains fixed within the crystals in the planes of cleavage. Subsequent heat treatment will eventually allow agglomeration of the hypereutectoid cementite more and more completely according to the number of cycles of heat treatment. AWC (10)

Casting Strains and Means of their Elimination (Ueber Gussspannungen und die Mittel zu ihrer Beseitigung) O. Bauer & K. Sipp. *Giesserei,* Vol. 23, May 22, 1936, pages 253-256. Annealing between 500° and 550° C. is sufficient to reduce harmful internal stresses. If annealed for not more than 2 hrs. the cementite does not disintegrate so that the mechanical properties are not deteriorated. Unnecessarily high annealing temperature (700° C. and more) should be avoided to prevent deterioration of mechanical properties because of disintegration of cementite at these temperatures. 6 references. Ha (10)

Decomposition of Solid Solution in Palladium-copper Alloys. P. S. Belonogov. *Metallurg,* Vol. 11, June 1936, pages 92-95. In Russian. Hardness, electric conductivity, microstructure and the thermal analysis study of the alloys indicated decomposition of solid solution with separation of a phase having a varying composition corresponding to Cu_3Pd and CuPd and present as isomorphous mixture. (10)

Some Studies in Microstructure of Zinc Coatings. W. E. Buck. *Journal American Zinc Institute,* Vol. 17, 1936, pages 70-75. A series of tests with hot dipped or galvanized sheets subjected to various types of service showed that the microscope, in many cases, is a valuable aid in confirming the information secured by other methods of analysis. A careful study of the mechanism and structures of coatings by means of the microscope will throw much light on unexpected coating failures and unsatisfactory sheet performance in service. RHS (10)

Magnesium Casting Alloys (Beitrag zur Kenntnis der Magnesiumgusslegierungen) H. Busch. *Giesserei,* Vol. 23, June 5, 1936, pages 291-295. A suitable method is described for making metallographic sections and the structure of the most used Mg alloys is explained. The possibility of changing the properties of Mg-Al and Mg-Zn alloys by heat treatment is discussed; Al-Mg alloys are only little improved by precipitation hardening, while the yield point of Mg-Zn alloys is increased by it about 75%, although the absolute value of the latter is lower than for Al-Mg alloys. The influence of heat treatment on the structure is demonstrated by photomicrographs. 12 references. Ha (10)

Chemistry of Intermetallic Compounds and Solid Solutions (Die Chemie der intermetallischen Verbindingen und Mischkristalle). U. Dehlinger. *Naturwissenschaften,* Vol. 24, June 19, 1936, pages 391-395. This short review touches on all important considerations necessary in the scientific study of the structure of alloys. It is pointed out that many of the classical laws and ways of interpretation of chemistry cannot be used in the present day study of alloy systems. While the data employed are purely chemical, new methods of using these data have been evolved from the use of electrochemical methods, X-ray and electron interference methods, refined magnetic and electric conductivity methods and the application of heat theory interpreted in the light of quantum mechanics. 9 references. 11. PROPERTIES OF METALS AND ALLOYS

Review of Research in Strength of Materials. F. L. Everett & J. L. Maulbetsch. *Journal of Applied Mechanics,* Vol. 3, June 1936, pages A67-A70. A list of 74 references pertaining to this subject. Ha (11)

Drill Stem. H. W. Fletcher. *American Petroleum Institute Drilling & Production Practice,* 1935, pages 150-157, discussion pages 157-161. Early rotary wells were drilled with low-carbon lapwelded drill stem; and difficulties arising from cross-threading, galling, rapid thread wear, and slow handling forced the development of the rotary tool joint. Increasing loads encountered, as well as depths increased, led to the introduction of medium-carbon seamless drill pipe with heavy upset and special thread form, together with heat-treated alloy joints. Recent changes in drilling practice adopted to decrease deviation of hole from vertical have emphasized certain factors which cause types of failure not previously general. The apparently simple drill-stem structure contains complicated design problems not susceptible of exact mathematical solution. The predominating type of failure is definitely fatigue, possibly accelerated by corrosion. Vibration, both torsional and transverse, is probably the principal destructive factor. Marked reduction of failures through metallurgical improvement is at present unlikely in the light of present knowledge. Some advantage may be secured through changes of design, although only by sacrifice in other directions, at the present less important. Much can be accomplished by greater care in the use of drill stem with special attention to those factors influenced by light weight and high rotative speed. VVK (11)

The Development of Rotary Drill Pipe. H. W. Graham. *American Petroleum Institute, Drilling & Production Practice,* 1935, pages 162-174, discussion pages 175-177. Follows briefly the long development of rotary drill pipe from its early form to a simplified mechanical design of advanced metallurgical quality. Specific points of importance were brought as follows: Early drill pipe was welded followed by seamless of higher strength. The ordinary pipe coupling was early replaced by the tool joint. The drill pipe was upset to compensate for reduction of all thickness in threading. The upsetting operation introduced metallurgical problems which require full-length normalizing for best results. A large proportion of failures occur in the threaded connection of drill pipe to tool joint. The last-engaged drill-pipe thread acts as a notch peculiarly susceptible to fatigue breaks under corrosive conditions. Drilling mud is a corrosive medium in promoting fatigue failures. There is no true fatigue-endurance limit under corrosive conditions. Twist-offs may occur by notch action under corrosion fatigue at very low stresses, particularly in older drill pipe. Drill pipe should not be cold-stamped. Welding the threaded connection of drill pipe and tool joint is an expedient, and not the best remedy for breaks or wash-outs. The use of welding to eliminate the threaded connection of drill pipe to tool joint involves difficulties that are unfavorable to the consideration of this method. The threaded connection of drill pipe to tool joint can be eliminated by forging an upset on the drill pipe of proper shape to act as a tool joint. Proper heat treatment of a forged integral joint of a special Mn steel produces a coupling adequate to tool-joint requirements. 5 references. VVK (11)

Slow-Bend and Impact Tests of Notched Bars at Low Temperatures. H. F. Moore, H. B. Wishart & S. W. Lyon. *Preprint American Society for Testing Materials,* June 1936, 6 pages. Results are given of slow-bend and impact tests of the following metals at temperatures ranging from ordinary room temperature to 40° below zero F.; S.A.E. Nos. 3135, 1020 and 1095, 60-40 brass, Cu and duralumin. The correlation between results from slow-bend tests and from impact tests over this temperature range is not greatly different from that found by Petrenko for ordinary room temperatures. The autographic slow-bend testing machine used is described. In a flexure test of a notched-bar specimen the friction of striking edge along the specimen seems to be a rather serious source of error, especially for specimens of metal so ductile that after the test they are not broken clean in two. Tension tests of notched specimens, both impact tests and slow-pull tests, are suggested as worthy of experimental study. VVK (11)

Present Status of Fabrication, Working and Use of Aluminum-Bronze (Gegenwärtiger Stand der Herstellung, Verarbeitung und Verwendung von Aluminiumbronze) E. Lay. *Werkstatt und Betrieb,* Vol. 69, June 1936, page 154. The alloys for technical use are of Cu plus 4-10% or more Al. The binary alloys with more than 11% Al are brittle; additions of Fe, Mn, Ni, Si or Zn permit increasing the Al to 11-12% without danger of brittleness. All Al bronzes are resistant to oxidation, especially at elevated temperatures, chemicals and seawater. The properties of the alloys are improved by heat treatment. Rolled and drawn wire of an alloy of 5% Al showed a tensile strength of 101.4 kg./mm.² and an elongation of 3.6%. HR (11a)

Nickel Brass (Neusilber) Rudolf Krulla. *Forschungsarbeiten über Metallkunde und Röntgenmetallographie,* No. 17, 1935, 64 pages. A brief monograph on Ni brass. Part I, dealing with properties, treats of color, melting point, hardness, strength and elongation, thermal e.m.f., electric resistance, thermal conductivity, and electrolytic potential. Part II, dealing with the influence of added elements, treats of the influence of Mn, Fe, Pb, Sn, Al, O, S, C, Si, P, Mg, Ag, As, Sb, alkali metals, and gases. Part III deals with melting, casting, working and annealing. Part IV deals with different possible defects. Part V contains information on corrosion resistance. Part VI is a discussion of physiological effects. Part VII is a discussion of applications. Part VIII is a bibliography of 9 references. JLG (11a)

"CHACE Thermostatic BIMETAL

USED Exclusively IN THE BRYANT GAS-FIRED UNIT HEATER"

THE BRYANT HEATER AND MANUFACTURING Co.

When "Bryant" and so many other leading manufacturers, whose products have such an enviable reputation for service and economy, adopt Chace Thermostatic Bimetal as standard, there must be some very good reasons.

If your product calls for reliable, automatic action at a given temperature, use Chace Thermostatic Bimetal. Sold in sheets, in strips or formed for assembly.

1615 Beard Avenue - - - Detroit Mich.

Relation of Temperature to Crystal Plasticity (Zur Temperaturabhängigkeit der Kristallplastizität) W. Boas & E. Schmid. *Zeitschrift für Physik,* Vol. 100, May 16, 1936, pages 463-470. Contrary to the Becker-Orowan theory, the authors found no relation between heating effects and crystal plasticity for crystals of Zn, Cd, Bi and Sn when subjected to plastic elongation under constant load both at room temperature and at 90° abs. FHC (11a)

Mechanical Properties of Pb-alloys. Kyukiti Simba. *Sumitomo-densen-iho,* July, 1936, pages 1-33. The elastic limit of Pb is 17 kg./cm.², while those of the alloys containing 3% Sn and 1% Sb are 39 kg./cm.² and 43 kg./cm.² respectively. From the results of alternate bending fatigue testing, Sn does not affect the endurance limit of Pb, but Pb alloys with 1% Sn and 0.05% Ca showed a marked increase of endurance. Rotating cantilever fatigue testing gave similar results; the fatigue limit of Pb was 17 kg./cm.² and that of Pb with 3% Sn was 27 kg./cm.², while those of Pb alloys with 1% Sb and 0.05% Ca were respectively 81 kg./cm.² and 125 kg./cm.² Under permanent static load Pb broke at 50 kg./cm.² The age-hardened Ca-Pb and Sb-Pb crept less than Pb and annealed alloys under small load. Sn-Pb alloy, however, showed more creep than Pb under a load less than 18 kg./cm.² Temperature had considerable effect upon the creep. The hardness of 1% Sb-Pb alloy at 150° C. was the highest among these alloys, but above that temperature was less than that of 3% Sn-Pb alloy. The tests are summarized as follows:

		Tensile Strength kg./cm.²	% Elong. in 4√A	Brinell Hardness	Yield Point	Elastic Limit	Endurance Limit
Pb	extruded	143	76	4-4.5	31	17	17
3% Sn-Pb	extruded	209	70	7-7.5	75	39(25)	27
1% Sb-Pb	extruded & aged	250	36	8.5-9.0	101	43	81
1% Sb-Pb	extruded & annealed	200	—	6.5-7.0	—	—	—
0.05% Ca-Pb	extruded & aged	300	45	9.0-9.5	—	—	—
0.05% Ca-Pb	extruded & annealed	220	60	7.0-7.5	—	—	—

Beryllium-Copper-Cobalt Alloys. F. G. Benford. *Metal Industry,* New York, Vol. 34, June 1936, page 226. Addition of Co to Be-Cu alloys lowers the amount of Be necessary for heat-treating to optimum physical properties. The principle use of this material has been in resistance welding equipment where good conductivity, hardness, and the ability to withstand severe heat are important factors. This alloy has been used as electrode material for all types of stainless steel resistance welding; spot, seam, flash, and projection; and in flash and projection welding of C steel. Another application is for electric soldering iron tips. CBJ (11a)

Nickel in Brass Foundry Practice. D. M. Curry. *Metal Industry,* New York, Vol. 34, Sept. 1936, pages 330-332. Properties of Ni bronzes are discussed. Ni in Ni-silvers imparts a silvery white color and increaeses the resistance to tarnish and corrosion. Effects of impurities on Ni silvers are noted. Foundry practice for Ni silver alloys and molding sands are discussed. CBJ (11a)

Aluminum Bronzes and Their Heat Treatment. M. G. Corson. *Metal Industry,* New York, Vol. 34, July 1936, pages 250-253. Physical properties, structure and applications of Al bronzes are discussed. Effects of alloying and heat treatments are considered. 3 standard alloys are: (1) 9% Al, 3.5% Fe, with or without 1% Mn and 1% Ni. (2) 10.3-10.5% Al, 4.5% Fe, 0.3% Sn with or without Mn and Ni. (3) 11% Al, 5% Fe, 1% Mn, 1% Ni. CBJ (11a)

Anomaly in Annealed Copper (Sur une anomalie du cuivre recuit) M. Cirou. *Revue de Métallurgie,* Vol. 33, July 1936, pages 413-419. Points to a close relation between the origin of Cu, its remelting practice and the temperature which gives the best ductility after annealing. JDG (11a)

Permalloys and Related Ferro-magnetic Alloys. J. G. Chaston. *Metal Treatment,* Vol. 2, Summer 1936, pages 58-66, 71; *Electrical Communication,* Vol. 15, July 1936, pages 38-51. A correlated abstract. The magnetic characteristics of high permeability alloys are outlined, and an account given of the developments which have followed Elmen's discovery of the 78.5:21.5 Ni-Fe alloy, permalloy. Higher permeabilities, secured with a simple anneal, have been found in certain of the Ni-Fe-Cu, Ni-Fe-Mo, and Ni-Fe-Cr alloys, while constant-permeability alloys have geen found in the Ni-Fe-Co series. The effects of crystal size and orientation, of the application of magnetic fields during heat treatment, and of cold work are reviewed, magnetic theories developed to account for the results outlined, and the influences of impurities discussed. 36 references. JCC (11a)

What is Phosphor Bronze? M. G. Corson. *Metal Industry,* New York, Vol. 33, Dec. 1935, pages 428-429. 2 types of phosphor bronze are used: (1) 4-6% Sn and minute amounts of P used for strips and wires but never cast. (2) 10-13% Sn and 0.05 to 0.5% P used for cast gears. P increases the fluidity of the liquid metal but not necessarily the "castability" since the amount of heat and heat conductivity are the important factors. Phosphor bronze must be made under the best controlled melting practice to prevent the molten metal from absorbing gas before the phosphor Cu is added. Since gear blanks are not cast to size but are machined the fluidity is of no importance. Since by the addition of P hardness is not enhanced, ductility is decreased, and ultimate strength is unaffected, the author finds no reason for the claimed superiority due to the use of the element. CBJ 11a)

A "Free Machining" Monel Metal. O. B. J. Fraser. *Iron Age,* Vol. 138, Aug. 13, 1936, page 37. Describes a new type of monel metal developed at the Huntington works of International Nickel Co. It is known as "R" monel metal. This machinable metal is produced by small addition of S. It is slightly less corrosion resistant than ordinary forms of monel metal. It is produced in different grades. Includes table giving comparison of relative mechanical strengths. VSP (11a)

Crystallization of Metals Without the Influence of Gravitation (La cristallisation des métaux sans influence de la gravitation) A. Glazunov & N. Lazarev. *Revue de Métallurgie,* Vol. 33, July 1936, pages 438-441. Mg was allowed to solidify slowly in a molten mixture of 85% LiCl + 15% LiF. As at 650° C. specific gravity of the mixture is 1.60, the same as Mg, the metal remained suspended in it in the shape of globules. This freed it from the influence of containing walls. Crystalline structure produced was exactly the same on the outside and in the center. The metal was perfectly solid. The same experiments were conducted with Al using a mixture of 40% $BaCl_2$, 45 $CaCl_2$ and 15 NaCl. JDG (11a)

Aluminum Alloy with Mg-Zn_2 Content as Casting Alloy (Die Aluminium-Legierung mit $MgZn_2$-Gehalt als Gusslegierung) H. Schmitt & P. Bergmann. *Aluminium,* Vol. 18, Aug. 1936, pages 370-373. The (German) Al casting alloy G54 contains Mg and Zn in such proportions that the compound $MgZn_2$ is formed. This alloy is suitable for sand and chill mold casting; it is particularly suitable for fixtures and fittings, in domestic appliances, shipbuilding and automobile manufacture. It is very corrosion resistant and, when coated by the eloxal process takes a silver-white or slightly yellowish tint. Methods of casting, hardening and surface treatment are briefly described. Ha (11a)

On the Growth of Gray Cast Iron. Hiroshi Sawamura & Jiro Yamamoto. *Suiyokwai-Shi,* Vol. 9, July 1936, pages 31-38. The author investigated the influence of various gases, such as ammonia, methane, water vapor, and mixed gas consisting of CO and H, on the growth of gray cast Fe, and also the influence of various atmospheric conditions on the graphitization of pearlite cementite in order to test the hypothesis of Benedicks and Löfquist that the irreversible abnormal expansion during repeated heating and cooling through A_1 transformation point is due to the graphitization of pearlite cementite produced during Ar_1 transformation. The results of the experiments confirmed the hypothesis of Benedicks and Löfquist. HN (11a)

Aluminium-magnesium Alloys. Pierre Vachet. *Aluminium & the Non-ferrous Review,* Vol. 1, Apr. 1936, pages 301-309. Translated from *Revue de Metallurgie.* See *Metals & Alloys,* Vol. 7, Aug. 1936, page MA 417L/6. JCC (11a)

Palladium and Palladium Leaf. Alan B. Thomas. *Metal Industry,* New York, Vol. 33, Oct. 1935, page 354. Pd, a member of the Pt group, is white in color, non-fading and non-tarnishable, is workable and easily alloyed. It has a high m.p. 1554° C.; its density is 12.16 or about 20% lighter than 18 karat Au. Pd is found in the Cu-Ni ores of Sudbury, Ontario. Pd is used in the decorative arts, in dentistry, jewelry, and electrical contacts. Pd leaf is 99.8% pure Pd and is produced similarly to Au leaf. CBJ (11a)

Age Hardening of Cast Aluminum Alloys Containing 9% $MgZn_2$ and their Mechanical and Corrosion-resisting Properties (Über die Veredlungsfähigkeit der Gusslegierung Aluminium + 9% $MgZn_2$ nach ihren mechanischen und Korrosions-Eigenschaften) Heinz Günther Wiechell. *Forschungsarbeiten über Metallkunde und Röntgenmetallographie,* No. 13, 1934, 52 pages. The theory of precipitation hardening is discussed. Cast and rolled Al alloys containing 9% $MgZn_2$ were heat treated to bring about precipitation hardening and their properties determined. The cast alloys responded to heat treatment just as did the wrought alloys. Degassing the alloys to be cast increased their apparent density. Hardness at elevated temperatures was determined and found to be high for Al alloys. The alloys were as resistant to sea water as the Al alloy "KS-Seewasser." The addition of 0.48% Ti had no effect on the properties of the alloys. 55 references. JLG (11a)

Free Cutting Aluminum for Screw Machine Work. L. W. Kempf & W. A. Dean. *Metal Industry*, New York, Vol. 33, Aug. 1935, pages 277-279. See *Metals & Alloys*, Vol. 7, Jan. 1936, page MA 30L/1. CBJ (11a)

Ductility Testing of Aluminum and Aluminum Alloy Sheet. R. L. Templin. *Preprint American Society for Testing Materials*, June 1936, 10 pages; *Sheet Metal Industries*, Vol. 10, Aug. 1936, pages 595-597. Because of the great diversity of opinions as to what constitutes ductility of a metal and as to just what measures this same quantity, a number of existing tests purported to give a measure of this property are reviewed. The results of bending tests are discussed from the point of view of comparisons with tension test data with evidence to show that there seems to be no reliable correlation between them. Some results of Erichsen tests are similarly discussed and data presentd to show that, here again, there is no reliable correlation between the Erichsen values and tension test values or bending test values. Difficulties involved in the Sachs ductility tests in arriving at indices of ductility are pointed out. Data from about 1500 observations of these various tests are discussed from the viewpoint that each type of test might offer some particular information regarding a particular type of forming but that no one or any combination of them appears to yield a general quality factor indicating by a single number the quality of the metal in the light of all of the varied definitions of ductility. Data for the simple 180° and repeated 90° cold-bend tests, the Erichsen test, the Sachs ductility test and the tension test are given for the following alloys: commercially pure Al in 3 tempers; soft, half-hard and full-hard; the Al alloys 3S, 4S, 52S, 51S and 17S. VVK + AWM (11a)

Effect of Iron Impurities on the Annealing of High Brass. W. A. Gibson & J. H. Doss. *Preprint American Society for Testing Materials*, June 1936, 6 pages. The paper gives the effect of Fe impurities on the annealing of high brass for temperatures from 600° to 1200° F. and for Fe impurities from 0.008 to 0.287%. In high brass having Pb and Fe as the only impurities, Fe contents as high as 0.09% are not harmful to annealing. In such material a great discontinuity in annealing properties occurs between 0.09% and 0.118% Fe. Fe greater than 0.118% is not harmful to sheet high brass provided proper allowance is made in processing and use for its annealing properties. If these allowances are not made it is very harmful. The explanation offered for the sudden discontinuity in the effect of Fe is the formation of a Cu-Fe-Zn compound at the grain boundaries during the initial recrystallization, this enveloping boundary preventing further amalgamation of grains until it reaches a high temperature at which it is taken into solution and annealing again occurs. VVK (11a)

Temperature Coefficient of Electric Resistance of Aluminum (Coefficient de témperature de la résistance électrique de l'aluminium) Maurice Henri. *Revue de Métallurgie*, Vol. 33, July 1936, pages 420-421. Temperature coefficient of electrical resistance was determined in the interval 20°-78° C. on cold drawn bars 8 mm. in diameter annealed at 320° C. for 3 hours and cooled in the furnace. The results obtained and reduced to 20° C. were: for 99.9% Al temperature coefficient was 0.00433 ± 0.00008, for 99.56% Al it was 0.00400 ± 0.00008, for 99.1 Al it was 0.00413 ± 0.00008, for 98.5 the figure obtained was 0.00400 ± 0.00008. JDG (11a)

Heavy Pressure Bearing Alloy Developed. *Steel*, Vol. 98, Mar. 30, 1936, pages 48, 50. Note on Nicuite, a bearing metal capable of carrying heavy loads at slow to medium speeds, developed by A. W. Cadman Mfg. Co., Pittsburgh, Pa. It has a yield-point in compression of 24,000-25,000 lbs./in.^{2}, tensile strength of 55,000 lbs./in.^{2}, yield-point of 48,000 lbs./in.^{2}, elongation in 2″ of 6-8%, and Brinell hardness of 100-120. MS (11a)

The Influence of Sodium and Calcium on Aluminum. B. F. Grashchenko & V. Darovskii. *Legkie Metallui*, Vol. 5, Jan. 1936, pages 17-37. In Russian. The presence of Ca up to 0.1% and of Na up to 0.04% does not affect the physical and mechanical properties of Al to any appreciable extent. Above these limits, Ca and Na decrease electrical conductivity and increase intercrystalline corrosion. Si decreases the influence of Ca by forming $CaSi_2$. HWR (11a)

Optical Constants of Copper-nickel Alloys. N. F. Mott. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Vol. 22, Aug. 1936, pages 287-290. The relation between optical constants and magnetic properties of Cu-Ni alloys is theoretically interpreted. Ha (11a)

More Developments in Stainless Steel. H. Etchells. *Metal Treatment*, Vol. 2, Summer 1936, pages 85, 88. A letter advocating the use of a high Ni content (about 30%) to insure stability of structure and freedom from weld decay in austenitic stainless steels. JCC (11b)

Influence of Molybdenum and Titanium on Low Carbon Chromium Stainless Steel. N. T. Gudtzov & L. N. Balakina. *Kachestvennaia Stal*, Vol. 4, No. 6, 1936, pages 52-53. In Russian. Influence of Mo and Ti addition to 0.1-0.2% C, 15-16% Cr steel was investigated. 3 and 4% Mo increase the depth of dendritic zone in ingots, 0.5% Ti entirely suppresses it, increasing grain growth. Mo reduces intensity of allotropic transformations, Ti renders steel ferritic. Heat resistance of the steel is decreased by Ti and increased by Mo. No pronounced improvement in corrosion resisting properties was observed. (11b)

Substitute Steels. K. P. Grigorovich. *Kachestvennaia Stal*, Vol. 4, No. 3, 1936, pages 7-12. In Russian. A review of gradual replacement of high alloy steels with those containing less alloying elements. (11b)

OFHC
REG. U.S. PAT. OFF.

OXYGEN-FREE HIGH CONDUCTIVITY

A Superior Copper
for All Purposes

OFHC Copper conforms to the A.S.T.M. Specification for electrolytic copper wirebars, cakes, etc., B5-27 with regard to metal content and resistivity, and is free from cuprous oxide.

OFHC Copper is characterized by its freedom from casting defects and its bar-for-bar uniformity. Its freedom from oxygen results in great ductility and toughness as evidenced by its high reduction of area and resistance to impact.

OFHC Copper withstands more working in hard condition when tensile strength is greatest, making it especially suited for products subjected to severe fabricating or service conditions.

Copies of a schedule of weights and dimensions of OFHC wirebars, cakes and billets, and a booklet containing technical information will be gladly furnished upon request.

Strength and Elastic Properties of Cast Iron. W. J. Schlick & B. A. Moore. *Iowa Engineering Experiment Station Bulletin No. 127*, 1936, 95 pages. This important piece of work is an outgrowth of the investigations carried on at this station for the A. S. A. Committee A-21 (on cast Fe pipe). It is the first study which has come to the reviewer's attention of the performance of cast Fe under combined tension and transverse stress, which is the usual condition of stress in underground cast Fe pipes lines. The authors use four cast irons of quite different properties, ranging from 36,000 to 67,000 lbs. modulus of rupture on the standard pipe bar (2″ x 1″ x 24″). Each Fe was cast in 3 different thicknesses, .5″, .9″, and 1.25″ and tests run in transverse, tension, and breaking loads in transverse stress with 20, 40, 60, and 80% improved tensile stress. All other properties of the usual nature are recorded, and the results shown to follow the equation:

$$R - R_1 = R\left(\frac{S_1}{S}\right)^{1.70}$$

in which R = ultimate flexural stress $\frac{Mc}{I}$ with no tension, S = ultimate tensile stress with no flexure,
R and S = flexural and tensile stresses when they act simultaneously. The corresponding relationship derived from the results of cast Fe pipe is

$$S - S_1 = S\left(\frac{}{R}\right)^2$$

The data from which the latter equation is derived are not yet released, but will be in a future publication of the experiment station. The 2 curves are quite similar. This bulletin represents a very careful piece of work and the conclusion will have an important bearing on the design of cast Fe pipe as well as other parts subject to such combined stresses. The present knowledge of the behavior of cast Fe in bending is critically considered in the light of the present tests. This section is unusually complete and is accompanied by an excellent bibliography. JTM (11b)

Some High-Temperature Properties of Niobium. A. L. Reimann & C. Kerr Grant. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Vol. 22, July 1936, pages 34-48. Specific resistance, total thermal radiation, and rate of evaporation of extremely pure Cb (less than 0.02% Sn as only impurity) was determined in the range of 1800°-2400° K. The lattice constant was found to be 3.2935 ± 0.0005 A. U., atomic weight 92.91 and density 8.58. The m.p. is 2770° K. Ha (11b)

Specific Heat of Nickel. E. C. Stoner. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Vol. 22, July 1936, pages 81-106. A detailed analysis of the specific heat of Ni was made which was found to be composed of 4 terms, c_p and c_v, as usual, and an electronic term c_e and a magnetic term c_m. The tests over a range of 1000° C. are described in detail. 21 references. Ha (11b)

Headquarters *for* Alloy Steels

Immediate Stock° Shipment

The newer, finer, money saving alloy steels are immediately available from Ryerson stocks. All major S.A.E. specifications, Tool Steels, Stainless and Heat Resisting Steels are carried in a full range of sizes. All other steel and allied products —the most complete stocks in the country are also carried to meet your requirements. Whether you need a few pounds or a carload, your order will have our personal attention and will be shipped at once.

Influence of Simultaneous Presence of Chromium and Manganese in Structural and Stainless Steels. A. B. KINZEL. *Kachestvennaia Stal,* Vol. 4, No. 5, 1936, pages 7-12. In Russian. Structural alloy steels can be subdivided into 3 groups, steels producing the desired physical properties without any heat treatment and used for large constructions, usual structural alloy steels the desired properties of which are developed by appropriate heat treatments and steels having a high content of alloying elements conveying to them stainless characteristics. Every element exerts a specific influence on the properties of the metal containing it. When the possibility of a suitable heat treatment is eliminated, the desired properties of steel can be obtained by balancing influences of different alloying constituents and their amounts. Many steels of this type are already on the market containing comparatively small percentages of cheap elements such as Cr, Si, Mn and Cu. In the stainless steel field considerable cheapening of the alloys can be obtained by replacing all or most of Ni present with Mn. Good results were obtained with a steel containing 18% Cr, 8 Mn, 1 Cu and 0.1 C. Quenched from 1050° C. it is composed of 60% austenite and 40% Cr-bearing ferrite. This 2-phase steel can be more easily rolled and drawn than straight austenitic steels. It has good physical properties, good machining characteristics, is cleaner than the usual 18-8, and can be welded more easily. It has some intergranular corrosion properties and cannot be stabilized by addition of carbide forming elements. In moist hot atmosphere it has better corrosion resistance than any stainless steel with the exception of 18% Cr, 6 Mn, 4 Ni and 1 Cu steel. See also *Metals & Alloys,* Vol. 7, Oct. 1936, page MA 507L/8. (11b)

Molybdenum-Tungsten High-Speed Steels. J. V. EMMONS. *Canadian Chemistry & Metallurgy,* Vol. 20, May 1936, pages 158, 160. An abstract. Various Mo steels and commercial Mo-W steels are briefly discussed, as well as tool steel inspection and heat treatment of high-speed steel. WHB (11b)

Nickel-Aluminum Compound, A Hardener for Steel. FRANCIS B. FOLEY. *Metal Progress,* Vol. 29, May 1936, pages 53-56. A Ni-Al-Fe alloy (C 0.03, Mn 0.16, Si trace, Ni 5.03, Al 2.59), produced in 4" square ingots was hammered to ½" square bars at 2050°-2075° F. with a Brinell hardness of 309 in the as forged condition. Quenching experiments were started at 1100° F., and then in steps of 100° up to 2100° F., duplicate specimens being heated for 15 min. to each temperature. There was practically complete absorption of the hardening compound at 1500° and higher, which was retained by water quenching but not by air cooling. By drawing at 1050° F. the hardness was increased for water quenching from 210 to 360 and for air quenching from 280 to 350. A 1300° F. quench after holding 12 hrs. followed by drawing 12 hrs. at 1050° F. produced the maximum hardness. The fact that 1050° F. draw produces the maximum hardness suggests possible combination of this hardener in high speed steel or nitriding steels where treatments are at similar temperatures. Magnetic Alloys of Iron, Nickel and Cobalt. G. W. ELMEN. *Bell System Technical Journal,* Vol. 15, Jan. 1936, pages 113-135. See *Metals & Alloys,* Vol. 7, Mar. 1936, page MA 146R/5. HFK (11b)

Working of Copper Steels (Le Travail des aciers au cuivre) E. HERZOG. *Métaux,* Vol. 10, Dec. 1935, pages 347-353. Cu steels are classed in 3 groups: (a) 0.3-0.5% Cu low C steel; (b) 0.5% Cu, 0.5% Cr, and medium C steels; (c) low C steels with 0.8-1.2% Cu. According to Hanson the solubility of Cu in Fe is 5% at 800° C., 0.4% at 600° C., and 0.2% at 20° C. Addition of 1% Cu will produce same hardness in steel as the addition of 0.12% C. Steels with 0.5% Cu can be cold worked as well as soft plain C steels. With Cu content higher than 0.50% there seems to develop some difficulty in hot rolling at temperatures higher than 1000° C. Cu steel should be rolled at 1100° to 1200° C. Steels with 0.5% Cu offer no difficulty on welding. GTM (11b)

Stainless Steels. W. H. HATFIELD. *Journal Institution of Production Engineers,* Vol. 15, Feb. 1936, pages 47-83. A general account of the discovery of stainless steels, their applications and properties. Tables showing the loss of weight of Ni, Cr, and Ni-Cr steels in HCl, H_2SO_4, and HNO_3 show that Cr additions afford protection from HNO_3 through the formation of a passive film and Ni gives increased resistance against HCl and H_2SO_4. In an appendix, notes are given on hot and cold working, welding, soldering, and machining of stainless steels. JCC (11b)

The Properties of Genuine Cold-Blast Pig-Irons. J. E. HURST. *Foundry Trade Journal,* Vol. 54, Jan. 30, 1936, pages 99-100. Orthodox metallurgical opinion today recognizes the fact that the properties and qualities of materials vary independently of their chemical composition. In the case of pig-irons, the most outstanding examples of the difference in properties and behavior for irons of similar chemical composition are to be found in the comparison of the properties of genuine cold-blast pig irons with pig-irons made by other methods. These differences are often referred to as inherent or intrinsic properties. These differences in properties are not confined to the mechanical strength. Genuine cold blast irons are tougher than other irons. Tensile strength is no criterion of toughness. The modulus of elasticity expresses a measure of the stiffness and the amount of permanent set, and the shape of the stress-strain curve gives valuable and quantitative data relating to the elastic properties. The area of the stress-strain curve or the value of the energy absorbed in breaking test specimens either in tensile or transverse loading is a much closer quantitative measure than the ultimate breaking strength. It is shown by the author that the modulus of elasticity of the foundry Fe is greater than the cold-blast specimen. In spite of the lower strength value, the resilience value in the sample of cold-blast Fe is greater than the foundry Fe. AIK (11b)

Mechanical Properties and Carburization Characteristics of Some Si, Mn, Cr and Cu Alloy Steels. S. S. KANFOR. *Metallurg,* Vol. 11, Apr. 1936, pages 75-89. In Russian. 13 steels containing about 1% of these elements either separately or in combination were studied. Physical properties were obtained after quenching in oil or water and after carburization and quenching. The steel which had the best physicals after heat treatment contained: 0.23 C, 1.14 Si, 1.50 Mn, 1.25 Cr. Its properties were close to the best Ni-Cr steels. After carburization the order of quality was entirely changed, and a steel with 0.20 C and 2.59 Cr was the best. Detailed description of the properties of all steels investigated is given. (11b)

Changes in Austenitic Steels on Tempering and Annealing. ANDRE MICHEL. *Metal Progress,* Vol. 29, June 1936, pages 72-74. In tempering hypereutectoid austenite 3 reactions intermingle:

1. Supersaturated γ solution → carbide γ solution with less carbide
2. γ solution → carbide and martensite
3. γ solution → martensite.

Reactions 1 and 2 take place during actual tempering and 3 takes place during the cooling. 5 references. WLC (11b)

Modern Trends in the Quality and Use of Cast Iron. R. S. MACPHERRAN. *Mining & Metallurgy,* Vol. 17, Apr. 1936, pages 182-186. Trends in manufacture and use of cast Fe are decidedly toward specialization, alloy Fe and increased strength. Discusses high test cast Fe and results obtained by Allis-Chalmers Mfg. Co. on tests of separately cast bars and bars from large castings. Considers the various present day alloy cast Fe and heat treatment. VSP (11b)

18-8 Is the Favored Stainless Alloy in Germany. BENNO STRAUSS & EDUARD HOUDREMONT. *Metal Progress,* Vol. 29, June 1936, pages 70-72. The application of stainless steels in Germany began with chemical industries and has spread to food equipment, architectural and automotive applications. 1-5% Mo addition is used for increased fatigue strength and resistance to hypochlorite. N_2 additions are found to refine the grain. Economic reasons affect the amounts of Ni, Cr and Mo used in German steels as they must be imported. Bimetals are widely used. Mn is substituted for Ni for economy. WLC (11b)

Abrasion Resistance of a Low Alloy Steel, Medium Manganese. F. A. WICKERHAM. *Metal Progress,* Vol. 30, July 1936, pages 64-66. Describes a new steel for abrasive applications which has tensile strength of 100,000-125,000 lbs./in.^{2} in as rolled condition and may be heat treated to 150,000 lbs./in.^{2} Usual fabrication methods apply. Composition is C 0.35-0.50, Mn 1.50-2.00, max. P 0.050 and S 0.055, Si 0.15-0.30. WLC (11b)

The Relative Values of White and Black Heart Malleable Castings to Production and Service. WALTER WEST. *Journal Institution of Production Engineers,* Vol. 15, Apr. 1936, pages 174-184. Includes discussion. Outlines the general characteristics of "black-heart" (containing 2.4% C, malleablized without loss of C to a structure of graphite and ferrite) and "white-heart" (made from 2.7% C iron annealed in Fe ore) malleable cast Fe. "Black-heart" castings machine easily and their use is extending. JCC (11b)

Electric Cast Irons (Les fontes électriques) *Journal du Four Electrique,* Vol. 45, May 1936, page 166. Besides the usual types of electric cast Fe some of the commercially produced irons contain Cr and Ti for use as ingot molds and Cr for heat resisting uses. JDG (11b)

Izod Toughness vs. Tensile Strength of Heat Treated S.A.E. Steels. *Metal Progress,* Vol. 29, May 1936, page 57. Graphs show this relation for most automotive steels. WLC (11b)

Cast Iron with High Mechanical Strength (Fontes à haute Résistances Méchaniques) Dudouet. *Usine,* Vol. 45, Mar. 26, 1936, page 27. The historical development of the improvement of cast Fe by producing a uniformly distributed pearlitic structure, advantages of such Fe, and means for obtaining it are reviewed. The best method is to melt cast Fe turnings (of about 60 mm. thickness) in the cupola, and add, at the moment of pouring, 0.5% Si, and, if S must be eliminated, Na_2CO_3. Pigs of 60 cm. thickness should be cast in order to have a small surface exposed to air, and they should cool slowly. Si-cast irons with less than 1.9% C have been obtained in this manner with a Brinell hardness of 201 and a deflection of 23 mm. under 650 kg. load. This cast Fe contains P which is an advantage. Ha (11b)

Manufacture and Characteristics of Carbon Steel. H. W. Graham & J. H. Flaherty. *American Petroleum Institute, Drilling and Production Practice,* 1935, pages 190-208. A comprehensive review of the subject covering blast-furnace pig iron, bessemer process, open hearth process, electric furnace steel, deoxidation methods, effects of constituents on properties, effects of working on properties, metallography of plain C steel and air-hardening Mn steels. 14 references. VVK (11b)

Production of Refractory Cast Iron (Fabrication des Fontes réfractaires) Guy Henon. *Revue de Fonderie Moderne,* Vol. 30, Apr. 25, 1936, pages 129-138. Modern types of heat resistant cast Fe are reviewed and the various chemical compositions described. Ha (11b)

Making Low Chromium Manganese Steel for a 75 Ton Railroad Crane. A. N. Jhironkin. *Kachestvennaia Stal,* Vol. 4, No. 6, 1936, pages 40-46. In Russian. Detailed description of making and properties of steel containing 0.15-0.22% C, 0.17-0.37 Si, 0.9-1.2 Mn, 0.4-0.7 Cr. No particular difficulties are involved in open hearth practice though care must be exercised. The steel has good physical properties in as rolled condition, though it is quite sensitive towards changes in rolling practice. (11b)

The Fe-Cr Alloy System. The Brittle, Non-Magnetic Phase. Eric R. Jette & Frank Foote. *Metals & Alloys,* Vol. 7, Aug. 1936, pages 207-210. A complicated structure, Σ phase, has been found to exist in binary alloys of high purity in neighborhood of the composition FeCr. Transformation of this phase is discussed as to rate in light of 3 factors of possible influence: (1) possible stabilization effect of Si on Σ phase, (2) an accelerating effect by Si, and (3) an accelerating effect of cold work. Experimental evidence tends to indicate (2) and (3) are more important factors. Transformation temperature of an alloy 50.6 at. % Fe is between 775° and 800° C. and is strictly reversible. WLC (11b)

Influence of Chemical Composition and Casting Temperature on Casting Properties of Iron. P. G. Petrov. *Liteinoe Delo,* Vol. 7, No. 6, 1936, pages 4-15. In Russian. Casting properties of gray and malleable irons were determined by casting spirals of standard design under production conditions. Metal was taken into 50 kg. ladles from cupolas. Desired additions were preheated and added to this ladle. Temperature was determined with an optical pyrometer. Fluidity in casting for both irons is a practically direct function of temperature. Si increases casting properties up to 3.5-3.8% Si in both irons when they contain 3.3-3.4% C. With higher Si content they decrease. This is connected with changes in the interval of primary crystallization. P was investigated only in the range 0.2-0.6%. It greatly increased fluidity. Mn, Cr (0.3-1.2%) and Ni up to 1% do not have any influence. (11b)

The Effect of Phosphorus on the Properties of Basic, Unalloyed Steel (Ueber die Wirkung des Phosphors auf die Eigenschaften von basischem, unlegiertem Stahl) A. Ristow. *Mitteilungen der Kohle und Eisenforschung G.m.b.H.,* Vol. 1, Nov. 1935, pages 49-84. The relation between P content and mechanically important properties of plain steel were investigated by statistical methods from results of a great many tests in different plants. As one of the principal conclusions it was found that the usually accepted harmful effect of P does not exist in fact; that, on the contrary, P in unalloyed C steel, whether produced in the open-hearth or in the Thomas process, is even desirable in amounts of about 0.08%, as this is a sure preventive to "sticking," especially in rolling of very thin sheets; a further increase would still be better but makes the sheets too stiff so that they will not be as good for deep-drawing. A very low P content, of 0.04-0.045%, makes the rolling of such sheets even almost impossible, and has other harmful effects inasmuch as the formation of non-metallic inclusions in heavy forgings is favored, wear increased and corrosion resistance lowered, and also forgeability and machinability are deteriorated. Care should, however, be taken to avoid too large segregations during the deoxidation period and casting. The P content shows a very close relation to O and Mn content, the O content is usually lower with higher P content. Literature is reviewed which also confirms that in the last 10 years, the P content in mild steel has in general gradually become higher. 86 references. Ha (11b)

Drillability of Cast Iron (Bohrzerspanbarkeit von Gusseisen) Herman Schropp. *Forschungsarbeiten über Metallkunde und Röntgenmetallographie,* No. 14, 1934, 102 pages. 7 different cast irons were studied. Bending, tensile, hardness, and wear-resisting properties were determined by different methods and an attempt made to correlate the different properties. The machinability as determined by drilling was compared with other properties. JLG (11b)

Substitute for a High Speed Steel. *Kachestvennaia Stal,* Vol. 4, No. 6, 1936, page 54. In Russian. 4 heats were made containing 1% C, 0.3 Si, 0.3 Mn, 4% W and 12% Cr. Forged at 850°-1080° C. and quenched in oil at 1075°-1100° C. the steel had 60 Rockwell. Drawn at 450° C. it had a hardness of 56-57 Rockwell. First results when used as milling cutters were satisfactory, but further experiments are needed to establish its quality. (11b)

The New Permanent Magnet Alloys. *Electronics,* Vol. 9, May 1936, pages 30-32, 35. Use of the Ni-Al-Fe alloys is discussed. Demagnetization and energy curves are presented. The effect of heat on the coercive force, as compared with high Co and W steel, and the loss of magnetism when the materials are dropped, indicate marked advantages for the new alloy. 7 patent references. DJM (11b)

ULTRA-CUT
STEEL

Fabricated from ¾" round Ultra-Cut with 16 double threads and ⅛" lead. Meets a machining problem better than SAE1112.

Specify this *High Speed Screw Stock of Industry* for your automatic screw machine department—and let it prove its economy by increasing your production. Ask for ULTRA-CUT FOLDER No. 3-M.

BETTER MADE STEELS LABORATORY TESTED

BLISS &
LAUGHLIN, INC.

HARVEY, ILL. *Sales Offices in all Principal Cities* BUFFALO, N.Y.

Electrical resistance of Faraday's steel samples; measurement of dissolved gas and other observations on melting a Faraday sample in an electric reflection furnace. (Elektriskt ledningsmotstånd hos några av Faraday framställda stålprov; bestämming av gashalt och vissa iakttigelser gjorda vid omsmältning av ett Faradayprov i den elektriska reflexionsugnen) Carl Benedicks. *Jernkontorets Annaler,* Vol. 120, Mar. 1936, pages 99-124. The electrical resistance of 18 small samples of Faraday steel preparations was measured by a special method depending on determining the potential drop between two points on a plane surface lying between two other points through which a fixed current is flowing. The apparatus was calibrated to determine the effect of thickness and irregularities in the perimeter, and an accuracy of $\pm 1\%$ was attained. The results agree well with previous work, and with the author's formula that 1 at. % foreign constituent always has the same effect, but better agreement is obtained by assigning individual coefficients to each constituent. Au, however, gives exceptionally high values, and in one Rh alloy the values were exceptionally low and in the other exceptionally high. Pt increases the resistance 7 micro-ohms/cm./cm.^{2} for each at. %. Melting of one sample containing 0.77% C. and 0.24% Si, released H_2 equivalent to 0.0004%, and N_2 equivalent to 0.006% by weight. The reflection furnace, which concentrates the heat on one side of the specimen, was found to cause softening first in the main body leaving the corners intact till the end, which is the opposite of the behavior in an ordinary oven where the corners melt before the main body, because they are exposed to radiation from all directions. It was also observed that pure Fe does not wet the walls of the crucible when melted in a vacuum, while C steel does because the C reacts with MgO to set free Mg which alloys with the steel. See also *Metals & Alloys,* Vol. 7, Sept. 1936, page MA 466R/10. HCD (11b)

The Influence of Special Elements on the Physical Properties of Cast Iron. J. W. Donaldson. *Foundry Trade Journal,* Vol. 54, May 28, 1936, pages 417-419, 423. Experiments carried out with Si additions up to 5% show the thermal conductivity to decrease as the Si content increases. This phenomenon only takes place so long as the graphite content remains constant, but when the amount of graphite is increased, there is a rise in the heat conducting value. Replacing Si by Ni causes an increase in thermal conductivity up to a maximum at about 3% Ni. In comparing the influence of special element additions on the thermal conductivities of cast Fe and steel, there are certain differences to be noted. In general the addition of Si, Mn, Ni, or Al to gray cast Fe is to produce a rise in its electrical resistivity. Additions of Co cause the resistivity to decrease, while with Cu the resistivity increases slightly to a maximum with 1% Cu and then decreases. General influence of Cr is to decrease the electrical resistivity of cast Fe. A systematic study of the influence of special element additions on the coefficient of thermal expansion of cast Fe has been made by Söhnchen and Bornhofen (*Archiv für das Eisenhüttenwesen,* Vol. 8, 1934, page 357). Partridge, in determining the influence of various metals on cast Fe, found that the form in which C is present greatly influences the magnetic properties. Graphite does not affect the hysteresis loss, but prevents the attainment of a very high magnetic induction. Ferrite gives low hysteresis loss and high permeability, while pearlite gives high hysteresis loss and low permeability. AIK (11b)

12. EFFECT OF TEMPERATURE ON METALS AND ALLOYS

L. JORDAN, SECTION EDITOR

The abstracts in this section are prepared in co-operation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

Nickel Steels at Low Temperatures. An investigation of the Impact Properties of the 2¼ Per Cent Steels. B. C. ALDRIDGE & GEORGE C. SHEPHERD, JR. *Metals & Alloys*, Vol. 7, June 1936, pages 147-152; July 1936, pages 185-192. Impact tests at temperatures from —75° F. to +70° F. are reported for A.S.T.M. V-notched specimens, A.S.S.T. keyhole notch specimens in various widths and Izod specimens. Results by different laboratories are correlated and conversion factors calculated to reduce all results to standard A.S.S.T. keyhole specimens. For brittle materials the shape of notch is of more influence than the cross sectional area but for tougher material the notch is of less effect and factors approach values calculated from the moments of inertia. Effects of heat treatment, location of specimens in or near welds, and the relation of notch to direction of rolling were studied. WLC (12)

Variation of Resistance and Structure of Cobalt with Temperature and a discussion of Its Photoelectric Emission. LOUIS MARICK. *Physical Review*, Vol. 49, June 1936, pages 831-837. X-ray diffraction patterns were obtained for Co in a camera designed for high temperature work. No crystallographic change for this metal has been observed in the region about 850° C. at which the change in the photoelectric emission has been reported. The α to β transformation is observed at 492° C. and no change in this transition temperature is detected by heating at 875° C. for a period of 55 hours. The variation of electrical resistance with temperature is extended to 1200° C. showing a change in slope occurring at the Curie point, determined as 1100° C. from these curves. An expansion of approximately 0.6% in the lattice edge is observed as Co is heated through the Curie temperature. No evidence of a reversion to the hexagonal form at 1015° C. has been observed. The temperature coefficient of expansion determined from these lattice measurements is $0.143 \times 10^{-4}/°$ C. and this agrees well with the macroscopic coefficient as determined by the usual methods. An explanation is suggested for the discontinuity in photoelectric emission reported at 850° C. WAT (12)

Continuous Contraction of Hot Valve Steels. JACOB FRIEDMAN. *Metal Progress*, Vol. 29, Mar. 1936, pages 70, 72. Describes irreversible contraction phenomenon noted in austenitic valve steel (Cr 13.0%, Ni 13.0%, W 2.0%, Si 2.0% and C 0.50%) when subjected to repeated heating and cooling. WLC (12)

Changes in Iron and Steel During Creep. C. H. M. JENKINS & G. A. MELLOR. *Metal Progress*, Vol. 29, Feb. 1936, pages 59, 80, 82, 84. See *Metals & Alloys*, Vol. 7, Jan. 1936, page MA 33L/6. . WLC (12)

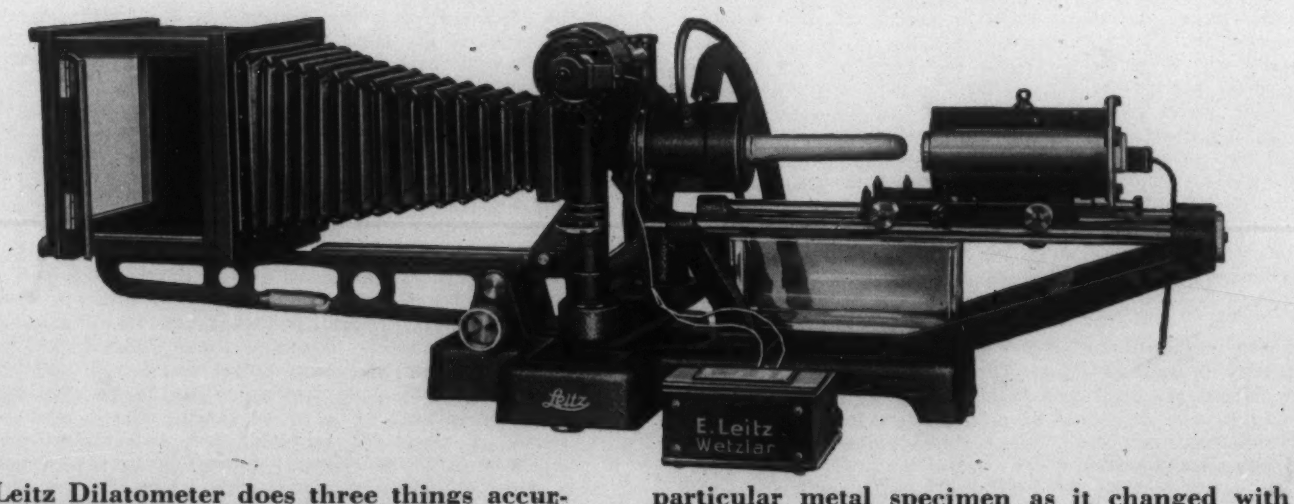
Note on the High-Temperature Strength of Cast Iron Especially in Thin-Walled Castings (Beitrag zur Warmfestigkeit des Gusseisens unter besonderer Berücksichtigung von dünnwandigem Guss) W. H. UHLITZSCH & W. LEINEWEBER. *Archiv für das Eisenhüttenwesen*, Vol. 9, Oct. 1935, pages 185-192. The elevated temperature strengths of a series of C and alloy cast irons are reported in graphs and tables. Tests of 13 alloy irons showed that when Si, Ni, Cr, and Mo were present the rate of fall in strength with temperature was lowered. SE (12)

Replacing Chromium-Nickel-Molybdenum Steels with Chromium Molybdenum Steels for Parts working under Conditions Leading to Increased Thermal Embrittlement. P. B. MIKHAILOV-MIKHEEV. *Kachestvennaia Stal*, Vol. 4, No. 5, 1936, pages 19-21. In Russian. Steels containing 0.3% C, 0.7 Cr, 3.5 Ni, 0.5 Mo used for fastening turbine parts working above 370° C. after 400 hours exposure have their impact value reduced from 6.5 to 5 kg.m./cm.^{2} and after 2000 hours to 2.6 kg.m./cm.^{2} Cr steel containing 0.3 C and 1.0 Cr loses 40-50% of its impact strength after 2000 hours. Steels containing 0.26% C, 0.75 Cr, 0.5 Mo remain fully ductile (10.8 kg.m./cm.^{2}) even after 2000 hours at this temperature if the steels are not strained. If, however, they are strained their impact value is reduced to 9.6 kg.m./cm.^{2} after the same exposure. Brittle range for Cr-Ni steels is limited to 450°-500° C., above and below which no embrittlement is observed. Cr-Mo steel has no brittle range. (12)

Determines

EXPANSION-TEMPERATURE CURVES

***Automatically* AND IN DETAIL**



The Leitz Dilatometer does three things accurately and automatically. It takes the metal specimen through any desired temperature range. It records the expansion curve. It spots the critical points.

On the plate is recorded the history of that particular metal specimen as it changed with changing temperatures.

If you want accuracy combined with utility in making thermal analyses of metals and other determinations, you should use the Leitz Dilatometer.

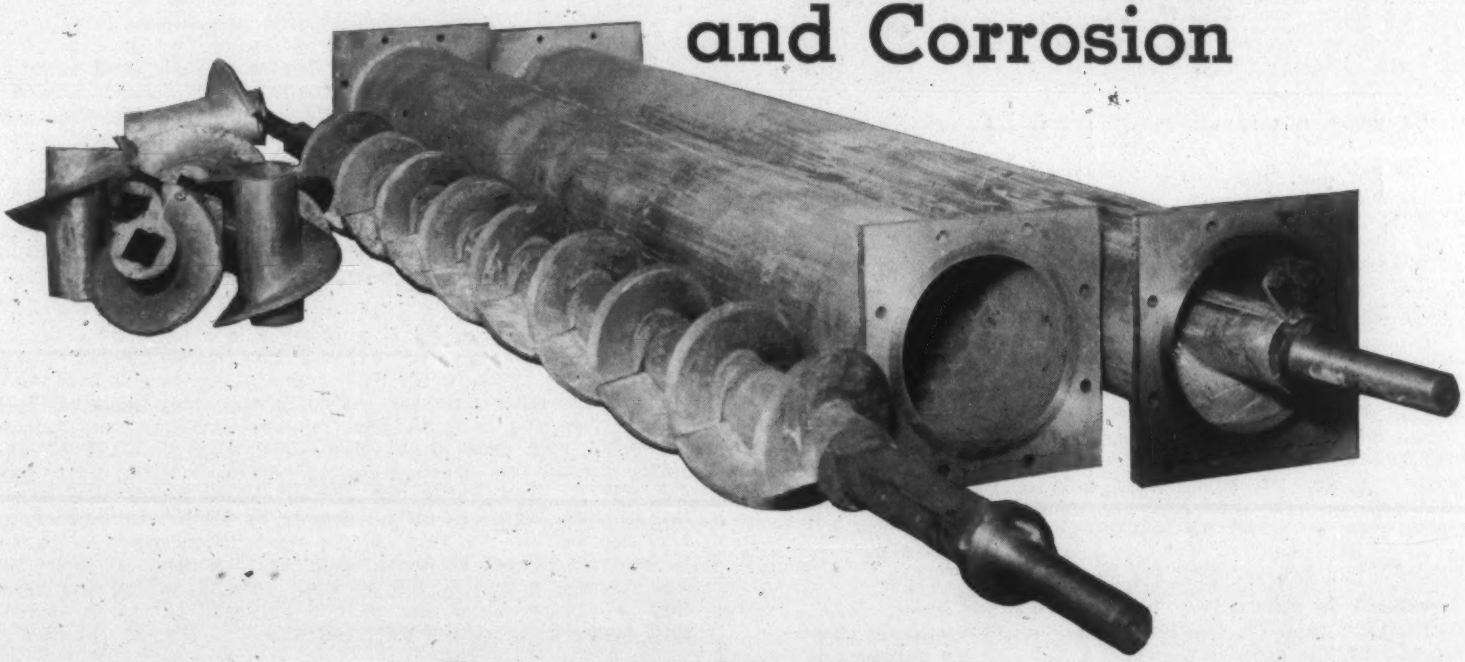
DURALOY

FORGINGS
CENTRIFUGAL CASTINGS
SAND CASTINGS

Assembled with Welding to Form SCREW CONVEYORS to Resist Heat and Corrosion

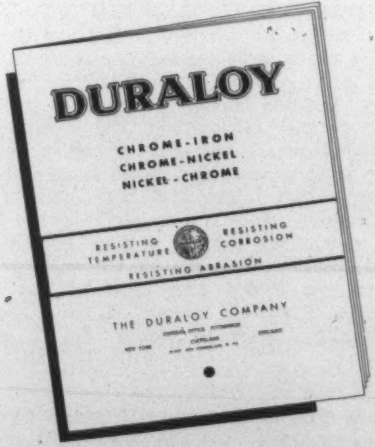


Three interesting facts are disclosed by these Screw Conveyors recently made in our foundry.

1 . . . of the many available DURALOY Chrome-Iron and Chrome-Nickel analyses, one was found that met this problem of heat and corrosion in a zinc smelter.

2 . . . three different forms were used: a forging, a centrifugal casting and sand castings.

3 . . . all the necessary machining and assembling with welding was done in our shop.



Send for our General Catalogue

Duraloy Metallurgists have had fifteen years experience in applying Chrome-Iron and Chrome-Nickel Alloys to problems of corrosion, abrasion and high temperatures. They have the necessary foundry experience and skill to turn out sound castings. They have facilities for complete machining and assembling. In short, Duraloy Metallurgists are in position to serve you 100%.

. . . .

The Duraloy Company makes all kinds of castings of Chrome-Iron and Chrome-Nickel; also centrifugal castings, formed shapes, bars, sheets, plates, bolts, nuts, fittings, etc.

13. CORROSION AND WEAR

V. V. KENDALL, SECTION EDITOR

Observations on the Oxidation of Steel. M. Baeyertz. *Transactions American Society for Metals,* Vol. 24, June 1936, pages 420-450. Paper presented and discussed at Chicago Convention of the Society, 1935. Study of the oxidation of plain C steels, S.A.E. 2330 and Cr steels with 5, 12, 17 and 27% Cr, 18-8 and 18-8 with 2.75% Mo shows oxidation to take place in a discontinuous manner caused by preferential oxidation of Si and Cr before oxidation of Fe. Stainless steels show the same general pattern of oxide forms as occur in other alloys but these similar oxide forms appear at different temperatures depending upon Cr content. The resistance of stainless steels to oxidation at high temperatures appears to be due to formation of 2 or more oxides high in Cr. WLC (13)

Galvanized Tank Corrosion on Automatic Water Heaters. A. F. Craver. *American Gas Journal,* Vol. 144, Apr. 1936, pages 29-32, 56; May 1936, pages 27-28. Causes of corrosion are divided into 3 groups: simple deterioration, external corrosion and contact corrosion. The presence of free O_2 in the H_2O leads to simple corrosion. External corrosion is caused by outside factors such as stray currents of radio grounds, etc. Contact corrosion results from the potential differences between unlike metals in contact with the same solution. Zn is electronegative to both Fe and Cu in the electrochemical series and is corroded when contact is made. A galvanized storage tank with brass and Cu fittings is therefore a galvanic cell. Agitation increases corrosion by causing more O_2 to be brought to the surface of the corrosing metal, by washing off the protecting film of H_2, and by loosening the protective coatings of alkaline salt and rust formations. Increase in temperature drives out the dissolved O_2 as nascent O_2 free to attack the corroding surface or to combine with the protecting film of H_2. Temperature also increases the electrical conductivity and produces greater localization of corrosion resulting in pitting. CBJ (13)

Metals in the Chemical Industry. Cecil H. Desch. *Chemistry & Industry,* Vol. 55, June 26, 1936, pages 169T-174T. An excellent treatise on the development of special metals and alloys for industrial use, brought about by increased corrosion problems in modern industry. Practically every metal and alloy is discussed, and the industry in which it is used to advantage. Corrosion fatigue and the impairment of physical properties, due to corrosion is fully explained and illustrated by graphical date. The otherwise well treated section on the effect of purity of metals on corrosion is marred by the misstatement of fact, viz., "99.99 Zn and Al when tested prove to be hardly attacked by HCl." AAA (13)

Electrochemical Mechanism of Corrosion (Der elektrochemische Mechanismus der Korrosion) U. R. Evans. *Korrosion & Metallschutz,* Vol. 12, May-June 1936, pages 105-107. At ordinary temperatures, the electrical current is the determining factor in corrosion by liquids. A direct chemical attack takes place only rarely. At high temperatures other conditions prevail as here the diffusion of O through the oxide layer must be considered. Recent experiments are reviewed which prove conclusively the electrochemical mechanism of corrosion. 16 references. Ha (13)

Corrosion Protection Value of Paint Films Indicated by Electrical Device. *Steel,* Vol. 98, June 29, 1936, pages 44, 46. Megohmeter is used for indicating effectiveness of organic finishes in excluding moisture. A lead from the instrument is connected to the bare side of a metal panel coated on the other side with a known thickness of paint to be tested. A drop of H_2O is placed on paint and a stop-watch is started. Other lead point is put into drop. Closing of circuit by penetration of H_2O through film will be indicated by galvanometer deflection. Time taken divided by film thickness in mils serves as an index of the corrosion-resisting ability of the paint film. MS (13)

Process Improves Corrosion Resistance of Zinc Surfaces. *Steel,* Vol. 98, June 1, 1936, page 43. Cronak process involves production of visible protective coating on Zn or Cd and on Zn and Cd plated metals, which materially reduces corrosion rate and prevents formation of white corrosion products. Film is produced by short immersion in an aqueous solution of $Na_2Cr_2O_7$ and H_2SO_4, and gives metal appearance similar to brass with a greenish-brown iridescence. Immersion of 5-10 sec. produces a brown coating on Zn alloy die castings. Immersion of 1-5 sec. produces a lighter iridescent coating. Tests indicate that process extends life of Zn coatings by at least 40%. MS (13)

"Go-Devils" and Radio Play Important Part in Cleaning Gasoline Pipe Line. *Oil & Gas Journal,* Vol. 34, Jan. 9, 1936, pages 28-29. Description of the cleaning of the Susquehanna Pipe Line Co., subsidiary of Sun Oil Co., gasoline pipe line from Marcus Hook, Pa., to Syracuse and to Cleveland. VVK (13)

The Work of the National Physical Laboratory. *Machinery,* London, Vol. 48, May 28, 1936, pages 259-260. Review of N. P. L. report for 1935 on contact corrosion under pressure, oxidation of solid metals, Mg, Al and Ca alloys for higher than room temperature use. WB (13)

Reconditioning An Old Water Main. Alfred B. Anderson. *Journal American Water Works Association,* Vol. 28, Aug. 1936, pages 1013-1016. Description of the cleaning and relining with cement of 5.5 miles of 48″ pipe of the water supply system of Newark, N. J. VVK (13)

Sucker Rod Breakage Can be Reduced by Use of Proper Design and Metal. Austin Allen. *Oil & Gas Journal,* Vol. 34, Feb. 27, 1936, pages 72A, 77A, 79A. Sucker rods are now designed for wells of the following types: (1) common rod for sweet oil only; (2) mild corrosion, medium weight; (3) extra strong for sweet oil only; (4) mild H_2S; and (5) bad H_2S. The various steels for these services are discussed and suggestions given for the care of sucker rods in storage, transportation, pulling and running. VVK (13)

Corrosion of Elektron Alloy AM503 by Leaded Fuels. Part I. Mechanism of Attack. G. D. Bengough & L. Whitby. *Journal Royal Aeronautical Society,* Vol. 39, Dec. 1935, pages 1144-1153. High anti-knock value fuels containing tetraethyl lead, corrode Mg-base alloy tanks so rapidly that such tanks cannot be used for leaded fuels. The mechanism of this corrosion is investigated as a preliminary step to developing protection methods. The alloy used contains max. 2.5% Mn, .2% each of Al, Zn and Cu, .4% Si, and the remainder Mg. The tests have been accelerated by increasing the amount of tetraethyl lead mix added to the gasoline as corroding medium, a procedure justified by the linear relationship between weight loss and volume % of the leaded mix. It is shown that (1) liquid water is essential to attack, (2) the separate constituents of the tetraethyl lead mix i.e. tetraethyl lead and ethylene dibromide, when added alone to gasoline and water, are not destructive. When mixed, however, intense attack occurs, (3) leaded technical benzol mixtures and water cause less attack than leaded straight run paraffin or napthene type aviation gas and water, (4) the dye is without effect on corrosion, (5) with constant water content, corrosion is directly proportional to the amount of tetraethyl lead mixture, (6) with constant tetraethyl lead mixture, corrosion rises to a maximum and then falls with increasing water content. FPP (13)

Corrosion and Protection of Metals in the New Patent Law (Korrosion und Metallschutz im neuen Patengesetz) E. Barth. *Korrosion & Metallschutz,* Vol. 12, July 1936, pages 177-178. Legal and technical principles in the new German law are explained. Patentability, procedure and infringement claims are discussed. Ha (13)

Electrolytic Contact Phenomenon of Commercial Steels (Contribution à l'étude des phénomènes électrolytiques de contact des aciers d'emploi courant) Georges Chaudron & Paul Lacombe. *Métaux,* Vol. 11, May 1936, pages 92-115. The improvement on the chemical and mechanical resistance of commercial steels by adding to these steels small amounts of metals such as Cu and Cr was investigated on 6 different steels containing 0.08-0.2% C, 0.5-0.8% Mn, 0.4-0.5% Cu and 0.4% Cr. When these steels were tested without the rolling scale on, the Cu steels were less electronegative than the C steels. With the rolling scale on, the Cu-Cr steels were more electronegative than the C steels. All tested steels have a dissolution potential of 0.7 volt in a 3% NaCl solution. GTM (13)

Motor Fuels and Corrosion (I carburanti e la corrosione) Sandro Doldi. *La Chimica e l'Industria,* Vol. 18, May 1936, pages 226-229. The corrosion of Al, Cu, bronze, Monel metal, mild steel and very hard steel in the presence of the following motor fuels was studied: alcohol, pure denatured, anhydrous, and hydrated; synthetic methanol, pure, denatured, anhydrous, and hydrated; gasoline d_{15}°-0.727; pure, S-free benzol, d_{15}° 0.860; crude benzol, d. 0.856, S-0.650%; spirits distilled from Ragusa shale, d_{15}° 0.840; S 3.0%; 97% distills between 65°-252° C. Results show that aqueous alcohols attack metal much more than the anhydrous; EtOH is not as corrosive as MeOH; the denatured alcohols are more injurious than the pure. Of the metals, Monel shows the highest resistance to corrosion; followed by bronze, brass, and hard steel; Al is the poorest. The least corrosive mixture is that of equal parts of gasoline and absolute EtOH. Next to gasoline, benzol free of S is the best. In general, alcohol gives very little trouble under ordinary conditions. AWC (13)

Report on Protective Coatings for Underground Pipes. A. B. Densham & F. C. Smith. *Institution of Gas Engineers, Copyright Publication* No. 115, 1935, 44 pages; *Gas World,* Vol. 103, Nov. 2, 1935, page 401; *Gas Journal,* Vol. 211, Sept. 11, 1935, pages 567-577. Accelerated methods for testing the efficacy of various protective coatings are described. Steel and wrought Fe service pipes corrode to much the same extent when exposed to electrolytic corrosion, so that both must be protected by a coating. Pitch troughing, bitumen asbestos sheathing, bitumen felt coating, bitumen hessian coating, thin adhesive bandage consisting mainly of hydrocarbon material (proprietary), and a bituminous paint (proprietary) covered with insulation tape all gave good protection against electrolytic corrosion. Pitch troughing in metal or cardboard moulds is an adequate method of protecting joints. Galvanizing, cotton fabric filled with grease (proprietary), cement troughing, and a bituminous paint (proprietary) applied over red Pb gave inadequate protection. The order of merit of the coatings investigated, judged from the electrical resistances, is roughly the same as the order judged from the amount of corrosion by an impressed current after 2½ years exposure. Probably the electrical resistance test gives a reliable measure of the protective power of a coating. 60 references. See also *Metals & Alloys,* Vol. 7, Sept. 1936, page MA 469R/2. AHE + MAB (13)

Mechanism of the Dissolution of Iron and Steel in Nitric Acid of Various Concentrations. Hikozô Endô. *Kinzoku no Kenkyu,* Vol. 13, July 1936, pages 316-332. In Japanese. The mechanism of the dissolution of Fe and steel in HNO_3 of various concentrations was studied. According to the writer's opinion, the dissolution of Fe and steel in HNO_3 takes place in 2 processes, i.e. the electrochemical process, and the direct reaction of oxidation (direct dissolution). In dilute solutions the dissolution of Fe and steel occurs chiefly in the electrolytic process, i.e. the hydrogen evolution type, and subordinately in the direct reaction of oxidation, while in the case of concentrated solutions, it occurs chiefly by the direct reaction of oxidation. The writer conveniently divided the ranges of the concentration into 5 parts from the results of various experiments and the mechanism of the dissolution in each range of concentration was studied. The formation of various dissolution-products, such as NH_2OH, NH_3, N_2, N_2O, NO, HNO_2, NO_2 and complex salt of $[Fe(NO)](NO_3)_2$ in the solution of each range of concentration were also taken into consideration; and the decomposition of the products of HNO_2 and the complex salt were also confirmed from the experiments. In the solution of the concentrated range in which periodic dissolution occurs, the portion of the surface of specimen in contact with glass was markedly attacked in the shape of the glass rod; this was explained by the stability of complex salts formed at that part. KT (13)

Corrosion Mitigation on the West Coast. Lee Holtz. *Gas Age-Record,* Vol. 77, Apr. 18, 1936, pages 403-407, 409. Paper presented before American Gas Association Distribution Conference, Apr., Memphis, Tenn. A general review of the experiences of the Southern California Gas Co. A system of soil survey and analysis which classifies soil into groups according to their corrosive natures has been developed. Detailed soil maps are prepared and careful records kept. Considerable success has been obtained in the use of Cu pipe in heavy alkaline soils, wherein both cast Fe and protected steel have an average life of 9 years. Cu pipe seems to have an indefinite life. No trouble has been experienced at Cu-steel junctions from galvanic action caused by dissimilar metals, when the joint has been properly protected with asphalt for a distance of 3 ft. each side of the junction. Either coal tar or hot asphalts are used for protective coatings; cold applied coatings are considered money wasted since they can not be applied in sufficient thickness, are porous and allow moisture to penetrate the film and contact the pipe and are compounded with materials offering little resistance to the corrosive element of the soil. The latest coating developed consists of (1) one coat primer on sandblasted pipe, (2) one coat asphalt, 175° melting point, 20 normal penetration, 4.5 ductility, (3) two wraps cellulose base paper, (4) one coat asphalt, same as No. 2 above, (5) one wrap Kraft paper. Dehydration of gas removes corrosion trouble from the gas. The methods most commonly used for correcting stray current electrolysis are (1) bonding the pipe to negative return feeders installed by the railway companies, or bonding direct to the negative buss of substations and (2) installation of reversing switches and insulating flanges. VVK (13)

Influence of Light on the Electrode Potential and Corrosion Phenomena of Mild Steel. C. O. Bannister & R. Rigby. *Iron & Coal Trades Review,* Vol. 132, May 8, 1936, pages 852-853. See *Metals & Alloys,* Vol. 7, Sept. 1936, page MA 470R/1. HA (13)

Theory of Corrosion Phenomena. IV. The Application of the Theory of Local Elements to the Problems of Corrosion (Zur Theorie der Korrosionserscheinungen. IV. Ueber die Anwendung der Theorie der Lokalelemente auf die Probleme der Korrosion) W. J. Müller. *Korrosion & Metallschutz,* Vol. 12, May-June 1936, pages 132-138. The correctness of the view that in the corrosion of metals, the formation of local elements between different places of the corroding metal is of primary importance is corroborated by a review of literature and the investigations of the author, and it is shown that the covering layer on a metal (film) plays a determining part. The distribution of the pores in this covering layer is about 10^9 pores/cm.^{2} surface; the metal in these pores is free and forms the anode of a local element in which the current flows back through the pores to the covering layer and the metal. On the strength of these observations, formulas are established by which the current and the amount of metal dissolved can be calculated. The thickness of the covering film is about 10^{-4} cm., and less in concentrated acids. 23 references. Ha (13)

Rapid Testing Method in Corrosion Investigations (Eine Schnellprüfungsmethode bei Korrosionsuntersuchungen) W. Palmaer. *Korrosion & Metallschutz,* Vol. 12, May-June 1936, pages 139-148. After a review of the theory of corrosion and testing methods for the attack of a metal, a new method is described which consists in covering the metal to be examined with a film of electrically good conductors of solutions of hygroscopic salts, as $CaCl_2$ or LiCl. The degreased and polished specimens are dipped in these solutions and suspended in a test tube which contains a few drops of the solution. The progress of corrosion can be observed with the eye and also determined by the loss of weight after certain periods. 14 references. Ha (13)

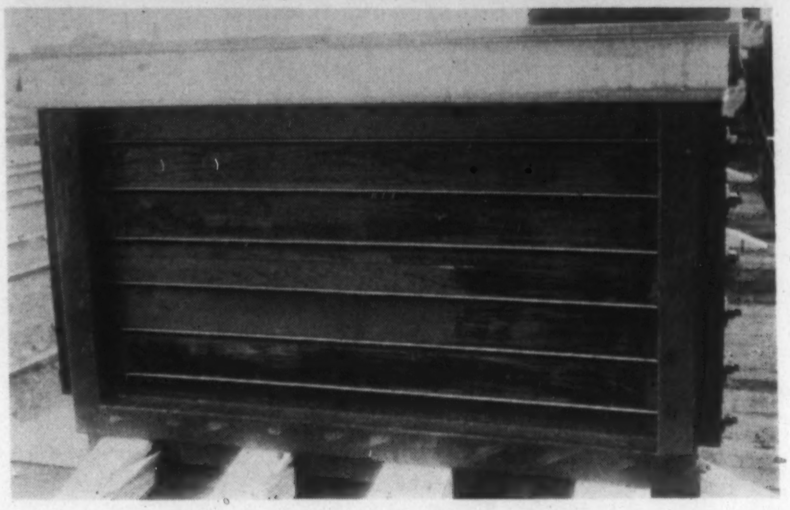
Influence of Oxygen on the Potential of Local Cathodes (Ueber den Einfluss des Sauerstoffs auf das Potential von Lokalkathoden) M. Straumanis. *Korrosion & Metallschutz,* Vol. 12, May-June 1936, pages 148-154. Local elements which are primarily responsible for metallic corrosion have only a low e.m.f. if O does not have free access to the element; however, the e.m.f. increases considerably and with it the corrosion velocity, if the O can get access easily. The reason for the increase is that H is bound to O as H_2O in the element and thus the decrease of H produces a nobler potential. 20 references. Ha (13)

Corrosion Fatigue of Drill Pipe. F. N. Speller. *American Petroleum Institute, Drilling & Production Practice,* 1935, pages 239-246, discussion pages 246-247. An investigation of the effect of mud fluids on the corrosion fatigue of drill pipe was initiated as a result of the exceptionally short life of a 4½″ grade D seamless drill pipe, apparently due to corrosion fatigue. The following conclusions were drawn. To avoid corrosion or corrosion fatigue on the outside of drill pipe, the metal should be protected from transverse scoring. It is also advisable to seal any openings at the joints as has been done by fusion welding. This practice not only prevents access of corrosive fluid, but also stiffens the joint so that it is stronger and there is less tendency for "rubbing" or "frictional" corrosion to develop. Contact effects and changes in velocity at the joints should be avoided as far as possible. The present practice of conditioning fresh-water mud, so that a high and stable colloidal content will be maintained, also protects the metal against corrosion and the chemical formation of notches under stress to a great extent. The alkalinity should be kept near the upper limit required for this purpose. To prevent corrosion, more field experimentation is desirable on the treatment of drilling mud. When soluble salts or other material are encountered that prevent satisfactory mud conditioning by their tendency to break down and flocculate the colloids, the useful life of metal under corrosion fatigue can probably be increased by reducing the free O with an excess of 100 to 200 p.p.m. of Na sulphite. If possible, this excess of sulphite should be maintained at all times and be controlled by tests at suitable intervals. Agitation of the mud-fluid stream in contact with air, and settlement of mud particles, both increase the rate of solution of O from the atmosphere. Therefore, particularly where de-oxidizing materials are added, the mud should not be agitated in contact with air more than is necessary. VVK (13)

Methods of Combating Corrosion and Electrolysis of Underground Lines. V. J. Sittel. *Oil & Gas Journal,* Vol. 34, Apr. 23, 1936, pages 46-47. Paper presented at the Petroleum Industry Electrical Association, Apr. 11, Tulsa, Okla. Any underground pipe line will have electric currents flowing on it caused by galvanic action of soil to iron pipe or by stray currents from railway or industrial power circuits. Protection by coatings is good only as long as the coating does not break down. Cathodic drainage maintained for 50% of the time will definitely check corrosion. .3 volt negative to the soil is necessary. VVK (13)

How many feet of Durimet tie-rod in this tank?

BUILT BY
HAUSER-STANDER
TANK CO.
CINCINNATI
OHIO



This Hauser-Stander pickling tank is approximately 6′ wide, 30′ long, 4′ high.

The tank is completely equipped with low-carbon (0.07%) Durimet ¾″ tie-rods, hex nuts, OG washers. For the tie-rods, four hundred and forty-nine feet, eight inches, was required, and one hundred and ninety each of nuts and washers.

The tank is to be used for a hot pickling solution containing ferric salts. That's why low-carbon Durimet is used—the usual alloy steels and non-ferrous alloys fail under such conditions.

If you have an acid condition that is hard to handle, try Durimet on it. All types of standard equipment is available—pumps, valves, heating jets, ejectors, tank outlets—as well as special forms.

May we assist you as we have others?

Electrolytic Corrosion in Imbedded Cast-iron and Steel Pipes, and Means Adopted to Reduce their Effect. I (Le corrosioni elettrolitiche nelle tubazioni interrate di ghisa e di acciaio, e i metodi adottati nella pratica per diminuirne l'entita. I) O. Scarpa. *La Metallurgia Italiana,* Vol. 28, June 1936, pages 257-267. Car tracks are subject to the corrosive action of stray currents. Varnishes, paints, etc. are not satisfactory protection, because they are readily scratched; coverings, such as with cement are very costly, and must be free of any flaws to protect. A good solution is to use double wires, so that the rail is not used as conductor. Good results have been obtained using a special insulator of bitumen, resin, or bitumen coated fabric between 2 layers of a fibre-containing cement. This insulator is being studied more fully. AWC (13)

Corrosion of Magnesium and Magnesium Alloys. Hachie Sawamoto. *Suiyokwai-Shi,* Vol. 9, July 1936, pages 39-46. The rate of corrosion of Mg and Mg-alloys in dilute acid and aqueous NaCl solutions were compared by the measurement of the gases evolved. From the experiments it is concluded that Cd is a desirable alloying constituent acting as anti-corrosive, but that it is less effective than Mn or Zn as reported in previous paper. HN (13)

Protection Against Corrosion of Iron by means of Arsenic (Korrosionschutz des Eisens durch Arsen) G. Tammann & H. Warrentrup. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 228, July 14, 1936, pages 92-96. As deposits on Fe and other metals are produced by heating in powdered As or by electrolytic methods. Smooth, bright deposit is possible with latter and fair protection against acid corrosion obtained with the As film. On bending, scratching or hammering the Fe plated with As, the As film breaks off and its protective value is lost. WB (13)

Wear Study of Hard Metals, Cast Iron, and Light Metals on the Wear-testing Machine of O. Nieberding (Abnützungsversuche an Hartmetallen, Gusseisen und Leichtmetallen auf der Abnützungsprüfmaschine von O. Nieberding) Reinhard Zimmer. *Forschungsarbeiten über Metallkunde und Röntgenmetallographie,* No. 18, 1935, 68 pages. Hard materials such as WC had a very high wear resistance. Additions of up to 0.5% Cr and 1.3% Ni increased wear resistance of cast irons. Al alloys that age hardened at room temperature had the greatest wear resistance. A given Al alloy had the highest wear resistance in the fully age-hardened condition. Hardness did not vary directly with wear resistance as determined by the Nieberding machine. 14 references. The Corrosion Problem in Steel. Andrew McCance. *Journal West of Scotland Iron & Steel Institute,* Vol. 43, Feb. 1936, pages 79-110. See *Metals & Alloys,* Vol. 7, June 1936, page MA 316R/7. FGN (13)

The Corrosion Problem in Steel. A. McCance. *Transactions Institution of Engineers & Shipbuilders in Scotland,* Vol. 79, Apr.-May 1936, pages 310-381. An excellent review of the nature of the corrosion of steel in the presence of water, with particular reference to the corrosion of ships' hulls. Mild steel, however it is made, and whatever impurities are present, is bound to corrode in aqueous solutions to a degree which depends only on the quantity of O which reaches the surface of the metal. Variations in the corrodibility of various solutions are largely due to differences in their power of dissolving O. Protection can only be afforded by removing dissolved O from the water or, when this is impracticable, by completely protecting the metal by a paint film. Incomplete protection, or the use of steels on which a partially protective film forms, may be very dangerous, as in these circumstances the total corrosion produced by the available O will be concentrated in a few areas and lead to dangerous pitting. The effect of mill scale on the corrosion of ships' plates is discussed and it is considered that the scale acts as such an O shield and this causes enhanced corrosion on the unprotected areas. No electrochemical action is thought to be involved in this case. The belief that modern steel corrodes more readily than pre-war steel is vigorously attacked, but it is pointed out that modern shipbuilding practice does not allow time for complete removal of the mill scale by weathering before painting, and may thus account for a difference in corrosion behavior of the hulls. A lengthy discussion is reported in which U. R. Evans contends that the conditions to which a ship's hull are subjected are different from those of total quiescent immersion and that considerations of corrosion velocities and corrosion probability in moving liquids lead to the conclusion that the tendency of localized corrosion and pitting varies very much from one variety of steel to another. The general opinion, supported by Bengough and others, appears to be against this conclusion. 51 references. See also *Metals & Alloys,* Vol. 7, June 1936, page MA 316R/7. JCC (13)

Topochemical Traits in Corrosion Phenomena (Topochemische Züge in den Korrosionserscheinungen) V. Kohlschütter. *Korrosion & Metallschutz,* Vol. 12, May-June 1936, pages 118-123. The definition of corrosion as "destruction of a solid body which is started on the surface by unintentional chemical and electrochemical attack" is discussed in all its ramifications and characteristics of the different types of corrosion are reviewed. It is attempted to establish a general morphology on the basis of the aggregate forms and disperse bodies as they are found in corrosion of solid bodies and crystals. The reaction of the corrosion products on the original condition of the attacked body is discussed and illustrated by the example of corrosion of Pb by air under pure water or dilute acids, on which the corrosion effects could be studied particularly well. Of special importance in the formation of reaction products are the so-called "somatoids" which are more or less regularly formed structures and can, under certain conditions, also be isolated. Somatoids as found in basic Al sulphite, Cu hydroxide, are reproduced in photographs. 10 references. Ha (13)

The Cast-Aluminum Base Denture. Dayton Dunbar Campbell. *Journal American Dental Association,* Vol. 23, July 1936, pages 1264-1270. The alloy used is one of Al and Mg (3.75% Mg) and designated by the producers as Alcoa No. 214. The author gives 5 reasons for the superiority for Al-Mg alloy denture: (1) Al is the only self-cleansing denture base material, (2) Al ranks highest among the usable metals, (3) Al may be permanently dyed the hue or color closely approximating that of gum tissue, (4) Al is the least expensive of all denture base metals, (5) Al denture base construction presents no greater difficulties than the cast Au inlay. The cost of metal for casting a base is about 5 cents where Au would cost 700 times as much. The author claims higher strength for the cast Al base and that the castings are so accurate swaging is not required. OEH (14a)

Filling Root Canals with Silver Points. Louis I. Grossman. *Dental Cosmos,* Vol. 78, July 1936, pages 679-687. The author finds Ag points more convenient to use than other materials which have been used to fill root canals and at the same time recognizes that it may have a degree of bacterial, inhibition through the oligodynamic effect. As a cementing material, he advocates a silver cement made of a powder containing 2 parts of precipitated Ag, 3 parts of powdered rosin, and 4 parts of ZnO (C.P.) which is mixed with a liquid of 9 parts of eugenol and 1 part of 4% solution of $ZnCl_2$., 35 references. OEH (14a)

Manifold Usefulness of Aluminum Powder (Die vielseitige Anwendbarkeit des Aluminiumpulvers) E. Hermann. *Aluminium,* Vol. 18, Aug. 1936, pages 376-381. The many possibilities of using Al powder in paints, as corrosion protection by tar-Al powder coatings, as light reflecting signs, for decorative purposes, heat-resistant and water-proofing coats, in pyrotechnics, etc., are reviewed and illustrated. Ha (14a)

Silver and its Uses in Chemical Plant. Arthur Haslam. *Metallurgia,* Vol. 14, July 1936, page 59. A brief review. JLG (14a)

Study of the Causes of Discontinuity of Metal in Sprues During Pressure-Casting. Raymond E. Myers. *Journal American Dental Association,* Vol. 23, Apr. 1936, pages 554-568. From many laboratory experiments, the author concludes that the discontinuity of metal in sprues during pressure casting is caused by the following conditions, either separately or in combination: (1) insufficient pressure to complete the casting; (2) insufficient heating of the casting metal, allowing the residue button to solidify before the pattern chamber and sprue are filled; and (3) insufficiency in amount of surplus metal to keep the sprue filled during the casting operation. The metal used in the experiments was a standard inlay gold, 3 to 5 pennyweights being used in each test. Extensive data are given and typical cases are illustrated by photographs. OEH (14a)

M. GENSAMER, SECTION EDITOR

Heat-, Rust- and Acid-resisting Steels. W. H. Hatfield. *Iron & Coal Trades Review,* Vol. 132, June 26, 1936, page 1147. Present types of heat-resisting steels include (1) plain Cr steels (12-30% Cr), (2) Si-Cr steels, (3) austenitic Cr-Ni steels, Cr and Ni each up to 30% with or without W and Ti and (4) higher Ni-Cr alloys, e.g. 60% Ni, 20% Cr. Chemical compositions and mechanical and physical properties of these groups and fields of their application are given in tables. Ha (14b)

Bath Tub Manufacture is Revolutionized. J. B. Nealey. *Industrial Gas,* Vol. 14, June 1936, pages 18-19, 24-25. Bath tubs are pressed of sheets of 99% pure Fe, pickled and coated with vitreous enamel of same expansion as the metal. Weights are thus reduced from 375-425 lbs. to 98-125 lbs./tub. Ha (14b)

Gage of Metal for Enameling. Charles S. Pearce. *Metal Progress,* Vol. 30, July 1936, page 63. Chipping of vitreous enamel on sanitary ware is blamed on the light sheet metal used. All stresses with the metal in service or installation must be within its elastic range. WLC (14b)

Cutlery Industry. D. A. Palmer. *Times [London] Trade & Engineering,* Vol. 38, Apr. 1936, page XVII. Reviews history and development. Pays some attention to use of stainless steel. MS (14b)

Low Carbon, High Chromium Alloy perfected in France. Albert Portevin. *Metal Progress,* Vol. 29, June 1936, page 70. 17-18% Cr steel with less than 0.10% C works very easily for making stampings. WLC (14b)

Machining Both Ends of Cast Iron Pipe in One Operation. I. S. Raidel. *Canadian Machinery,* Vol. 47, May 1936, pages 23-24, 56. Description of method of making precise, metal to metal joint in cast pipe which may then be joined at any angle with good fit due to tapered machining. WB (14b)

Stainless for Aircraft Design and Fabrication. Wilson L. Sutton. *Metal Progress,* Vol. 29, June 1936, pages 40-44. On a weight-strength basis there is little to choose between duralumin and stainless but the latter is more applicable to large structures and heavier loads. Welding technique in aircraft construction is discussed. WLC (14b)

15. GENERAL

RICHARD RIMBACH, SECTION EDITOR

The Chemists' Year Book. 1936. Founded by F. W. Atack. Edited by E. Hope. Chemical Publishing Co., New York, 1936. Fabrikoid, 4 x 6¼ inches, 1,257 pages. Price $6.00.

The editorial control of this British yearbook changes with the present edition from Dr. Atack to Dr. Hope. The sections of the book of special interest to metallurgists are: Thermal Constants of Elements; Physical Constants of Elements and Alloys; Melting Points of Some Special Alloys; Crystallography; Properties of Minerals; Spectrum Analysis; Fuels and Illuminants; Lubricants; and Analysis of Clays, Firebricks and Silica Materials. R. Rimbach (15)—B—

Better Returns from Scrap. E. G. Wertheimer. *Metal Industry,* New York, Vol. 33, Sept. 1935, pages 316-318. Industrial non-ferrous metal scrap can be classified as follows: (1) Scrap from production departments, (2) scrap from maintenance operations, (3) scrap from dismantling operations. Scrap from production includes (a) borings and turnings from machining operations, (b) skeletons, clippings, and short ends from punching and shearing operations, (c) solids found defective during course or completion of all operations, (d) metallic residues, skimming drosses, etc. accumulated through certain meltings or plating operations, and (e) certain classes of non-ferrous metals used to process production items. Items of importance in scrap selection and preparation are discussed. CBJ (15)

Research Activities of Mellon Institute Reach Quarter-Century Mark. E. R. Weidlein. *Steel,* Vol. 98, Apr. 20, 1936, pages 61, 94. Excerpt from 1935-1936 annual report, dealing with advances made at the Institute in heat insulation, refractories, and ferrous metallurgy. MS (15)

Simplify Proposed Color Code for Marking Steel Bars. *Steel,* Vol. 98, June 15, 1936, pages 37, 40. Deals with development of revised code approved by the National Association of Purchasing Agents and tabulates colors and color combinations decided upon to identify various S.A.E. steels. MS (15)

Index and Directory to the Manufacturers of Fabricated Parts and Aircraft Materials. *Aero Digest,* Vol. 29, July 1936, pages 66, 70. WB (15)

Cyanide Poisoning. K. K. Chen, C. L. Rose & G. H. A. Clowes. *Metal Industry,* New York, Vol. 34, Sept. 1936, page 346. Precautions for handling cyanides are listed. CBJ (15)

15a. Economic

Zinc Industry in 1935—Advance Summary. H. M. Meyer. *United States Bureau of Mines, Mineral Market Reports* No. M. M. S. 446, Mar. 31, 1936, 3 pages. Statistical. AHE (15a)

Rolled Zinc in 1935—Advance Summary. H. M. Meyer. *United States Bureau of Mines, Mineral Market Reports* No. M. M. S. 448, Apr. 23, 1936, 2 pages. Statistical. AHE (15a)

Tool Steel. William F. Osborn. *Times [London] Trade & Engineering,* Vol. 38, Apr. 1936, page XXVIII. Discusses briefly adoption of new methods by the tool-steel industry of Sheffield, England, and its part in British national economy. MS (15a)

The Swedish Steel Industry. H. Dahlerus. *Iron & Coal Trades Review,* Vol. 132, Apr. 24, 1936, page 752. After some historical data of the development of the Fe and steel production in Sweden, modern production statistics are given. Charcoal pig Fe is still the fundamental element in the quality of Swedish steel. Fairly poor ores are used which are finely crushed and concentrated; by sintering the concentrates the S content is considerably reduced. As the charcoal pig Fe is practically free from P, S and Cu it is particularly well adapted for steel-making. The acid open hearth is mainly employed for high-grade steels, the basic process is used for the manufacture of commercial steel. Electric furnaces are now used of capacities of 20-25 tons, the principal types being the arc furnace and, lately, the high-frequency furnace. Ha (15a)

The Usurpation of Patents in Spain (La usurpacion de patentes en Espana) Ramon Pella. *Metalurgia y Construccion Mecanica,* Vol. 2, July 1936, page 8. The lawyer explains to the engineer how to proceed to protect his patents in Spain. FPM (15a)

15b. Historical

From the History of Aluminum (Aus der Geschichte des Aluminiums) M. H. Haas. *Aluminium,* Vol. 18, July 1936, pages 332-348. Biography of Martin Kiliani, who developed the electrolytic production of Al in Germany, is given. Ha (15b)

Historic Sources of Foundry Practice. S. O. Birula. *Liteinoe Delo,* Vol. 7, No. 5, 1936, pages 16-23. In Russian. (15b)

Fiftieth Anniversary Marks Progress in Casting Aluminum. H. J. Rowe. *Foundry,* Vol. 64, Feb. 1936, pages 22-24, 63-64, 66, 69. Gives historical review of the Al industry from Charles M. Hall's discovery of the electrolytic process of Al manufacture to the present time. VSP (15b)

FOR SALE

Complete large B & L Metallographic Microscope, inverted type with 8 x 10" Camera, optical equipment No. 12, complete set of additional lenses and items for macro work; stand and shock absorber; outfit is about four years old but hardly used; listed at approximately $1,600, will sell at $750. Write to Spindler & Sauppe, Inc., 86 Third St., San Francisco, Calif.

FREE SERVICE DEPARTMENT

Junior Executive Available—M. I. T. Graduate. General engineering experience, Chase Brass and Copper Company. Purchasing chemicals and equipment, R. H. Macy and Company. Single, christian, references. Box No. MA-4, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

POSITION WANTED: INSPECTOR, SUPERVISOR or INSTRUCTOR of WELDING. Specialized 8 years in arc welding. Knowledge of Metallography, Heat-Treating and Physical Metallurgy. Capable of performing tests and conducting investigations of Weld-Metal. Sales experience. Member of American Welding Socy. and American Socy. for Metals. Good Linguist. Consider position outside U. S. Available July First. Address box MA-6, care of METALS & ALLOYS, 330 W. 42nd Street, New York, N. Y.

MARKET RESEARCH SPECIALIST with a good technical background. Complete developing and marketing experience on electrical and chemical specialties and instruments. Salary or fee basis. Box MA-9, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

AVAILABLE — METALLURGIST — Technical graduate—35 years—8 years metallurgical supervision over all phases of special steel manufacture, including melting. Address Box MA-11, c/o METALS & ALLOYS, 330 West 42nd St., New York, N. Y.

REPRESENTATIVE WANTED: Industrial furnace manufacturer wants experienced sales engineer familiar with middle west territory and with some metallurgical knowledge. Commission basis. Address Box MA-12, c/o METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

WANTED: By large, well-known buyer of Metal Alloys and Residues containing Nickel, Chrome, Etc.—Representatives who are acquainted with the Steel—Chemical—Heat Treating, Heat Resisting, and Automobile Industries. We offer a very attractive proposition to the right man. Reply, giving references and qualifications. Also, cities and states which you cover. All references and qualifications will be kept strictly confidential. Box MA-13, METALS & ALLOYS, 330 West 42nd Street, New York, N. Y.

WELDING ENGINEER, metallurgical experience with sales background. Experience in design, estimating and research, sheet metal and heavy structures. Not actively employed at present. Permanent connection desired. Box MA-14, care of METALS & ALLOYS, 330 West 42nd St., New York, N. Y.

METALLURGIST, immediately available. Technical graduate, studied under Dr. Albert Sauveur and Dr. V. N. Krivobok. 3 years of practical experience in research on failures, development and plant control of alloy and plain carbon steels. Also 3 years of experience in ore dressing and mining engineering. Single, 33 years of age, no preference to location. Address Box MA-15, METALS & ALLOYS, 330 W. 42nd St., New York.

METALLURGIST available. A young Dutch metallurgist, now employed in the laboratory of a machine and chain works in Holland, wants to get a chance in the U. S. A., with opportunities for increased responsibility and salary. Box MA-16, METALS & ALLOYS, 330 W. 42nd St., New York.

METALLURGIST desires position in applied research, ferrous preferred. Thoroughly experienced in metallography, X-rays, physical testing, etc. Experience gained in research laboratories, steel plants, and field. Employed. Box MA-19, METALS & ALLOYS, 330 W. 42nd St., New York.

METALLURGIST, *Physical Chemist*: Ph.D. '31, age 33. Five years' experience in physical metallurgy—corrosion, metallography, heat treatment and finishing of stainless and alloy steels. Practically familiar with newest methods of testing and investigation in metallurgy. Can initiate and direct research. Employed, available on short notice. Box MA-18, METALS & ALLOYS, 330 W. 42nd St., New York.

SALES ENGINEER with an established Chicago office desires a steel and alloy tubing account—for territory covering Illinois, Wisconsin, Indiana and Southern Ohio. Box MA-17, METALS & ALLOYS, 330 W. 42nd St., New York.

MANUFACTURERS' LITERATURE

Oven Furnaces

The line of improved oven furnaces is described in an illustrated leaflet which lists the desirable features to be found in these ovens. American Gas Furnace Co., Elizabeth, N. J. (1260)

Temperature Control

An all electric automatic control which operates on the radio principle is described in an illustrated leaflet. The manufacturer claims that this principle makes possible the most dependable and closest automatic control available today. Wheelco Instruments Co., Chicago, Ill. (1261)

Ajax-Northrup Electric Furnaces

Bulletin No. 10, devoted to the oscillator or spark-gap type converters and furnaces supersedes Bulletin 7. General principles of this equipment are discussed. Illustrated. Ajax Electrothermic Corp., Trenton, N. J. (1262)

A New Motorblower

Type CS Motorblower which was designed to meet the needs of the services requiring air at one-pound pressure in volumes from 325 to 3200 cubic feet per minute is described and illustrated in a pamphlet distributed by Ingersoll-Rand, New York, N. Y. (1263)

High Temperature Insulation

For all types of heated equipment is the subject of an illustrated leaflet issued by Armstrong Cork Products Co., Lancaster, Pa. (1264)

Repeated Stress Machines

These machines for determining the endurance limits of bar, wire and sheet metals are illustrated and described in a pamphlet which claims speed, accuracy, economy and convenience as their chief features. G. N. Krouse, New Kensington, Pa. (1265)

Stainless and Heat-Resisting Steels

A colorful booklet devoted to the Enduro line of steels illustrates many of the applications. Tables of the properties of these steels and laboratory corrosion data are included. Republic Steel Corp., Massillon, O. (1266)

Rapid Grinding Manual

This manual, GM-36, describes and illustrates the complete procedure of the latest technique for rapid, economical grinding of Carboloy tools. It is recommended as a practical instruction booklet for all carbide tool users. Carboloy Co., Inc., Detroit, Mich. (1267)

Scientific Metal Cleaning

Solvent degreasing and alkali cleaning are discussed in this illustrated booklet. Three basic types of degreasing machines—vapor, immersion and spray—are described. Detroit Rex Products Co., Detroit, Mich. (1268)

Ladle Fluxes

The advantages of using fluxes for aluminum, brass, bronze, copper nickel, iron and special alloys are listed in a leaflet of The Maluminum Co., Indianapolis, Ind. (1269)

Vanadium Steels for Locomotive and Car Construction

For each type of steel discussed this comprehensive booklet provides tensile properties under recommended methods of heat treatment and considers the relationships of these properties to the applications suggested. Illustrated. Vanadium Corp. of Amer., New York, N. Y. (1270)

Zinc Alloy Die Castings

This supplement of "A Visual Report of Progress" brings the progress being made in the die casting industry up to date. These photographs were intended as a cross section of die casting ideas. The New Jersey Zinc Co., New York N. Y. (1271)

Silicon-Chromium-Molybdenum Steels

A booklet devoted to Sicromo 1, 2, 3 and 5 steels, gives the analyses of the steels and discusses the effect of both silicon and chromium on the oxidation resistance of steels in which they are used. The Timken Steel & Tube Co., Canton, Ohio. (1272)

Metal Surface Preparation

This manual outlines the procedure to be followed for the various applications of sodium cyanide in the preparation of metal surfaces. E. I. du Pont de Nemours & Co., Inc., Wilmington, Del. (1273)

Combustion Safeguard

A materially improved line of Protectoglo equipment is described in Bulletin No. 90-1. This apparatus includes two separate and distinct types of relays, and a flame sensitive electrode which can also be used as a special spark plug for electric ignition. The Brown Instrument Co., Philadelphia, Pa. (1274)

Molybdenum in Steel

Data on different types of molybdenum steels are given in an illustrated booklet of the Climax Molybdenum Co., New York, N. Y. (1275)

Chain and Belt Conveyors

Bulletin 1-B discusses conveyors for use at high temperature. The advantages of this company's products are described and the capacities of the chain and belt conveyors given in tables. Michigan Steel Casting Co., Detroit, Mich. (1276)

Electric Furnaces

Bulletin No. 51 describes a few of the furnaces manufactured by this company. This equipment, although it covers a fairly wide range of manufacturing requirements, represents only a small portion of this company's furnaces. C. I. Hayes, Inc., Providence, R. I. (1277)

Temperature Control Instruments

Bulletin No. 456 is devoted to this company's pyrometer controllers. Illustrated. The Bristol Co., Waterbury, Conn.

Published by the same firm: Bulletin 457 is devoted to this company's Pyrotrol which is a safety device for gas-fired industrial ovens and furnaces. (1278)

Bearing Bronzes

A leaflet of interest to engineers lists the methods used to eliminate oxides from the finished product. Tables to aid in the choice of the proper alloy are included. The Johnson Bronze Co., New Castle, Pa. (1279)

Where and How to Prevent Corrosion

Bulletin L-36 discusses the use of certain of this company's compounds as rust-preventives and indicates formulae to be used and results obtained. The materials are manufactured from fractions of petroleum by means of a process of controlled oxidation. Alox Corp., Niagara Falls, N. Y. (1280)

Industrial Applications of the X-Ray

The application of X-ray examination to castings, welding and food products and X-ray diffraction are discussed in some detail in the profusely illustrated publication 8A-54 of the General Electric X-Ray Corp., Chicago, Ill. (1281)

Turbo-Compressor Data Book

This Data Book No. 107 was prepared to give accurate and brief information on the engineering characteristics of turbo blowers and exhausters. General information on the application of this company's blowers to gas and oil burners, and miscellaneous applications for other types of work are included, as well as rating tables. Illustrated. The Spencer Turbine Co., Hartford, Conn. (1282)

Testing Machines

Catalog 50, Part L, features Olsen Universal testing machines. Complete descriptions and illustrations. Tinius Olsen Testing Machine Co., Philadelphia, Pa. (1283)

Heat in Industry

A well illustrated booklet entitled "Wherever Heat is Used in Industry" gives a picture of this company's products and service. According to this booklet their equipment is being used, and giving the highest degree of efficiency in heat treatment of metals, manufacturing glass, enameling, etc. Surface Combustion Corp., Toledo, O. (1284)

Forging Rolls

Bulletin No. 91 claims that these wide adjustment forging rolls are completely modernized machines with improved mechanical operation, increased economy and efficiency of this forging method and improved quality of the product. Ajax Manufacturing Co., Cleveland, O. (1285)

Micromax Thermocouple Pyrometers

A new catalog, N-33A, explains the potentiometer method of measurement, the operation of the mechanisms through which this balance method is made available to industry. The complete line of instruments is set forth. Leeds & Northrup Co., Philadelphia, Pa. (1286)

Polishing Machines

A portable model and a floor model of these new metallographic machines are described and illustrated in a pamphlet from Eberbach & Son Co., Inc., Ann Arbor, Mich. (1287)

Heavy-Duty Black

Triple-A No. 20 heavy-duty black is the full name of this coating for steel which, according to the manufacturer, resists acids, alkalies, brine, moisture, abrasion and sulphurous fumes. Quigley Co., Inc., New York, N. Y. (1288)

Furnace Element Construction

Bulletin HD-636 describes the development of the Hevi Duty element construction in furnaces. Some of the features of these elements are: freely radiated heat from the heating coils; coils are free to expand and contract; and tolerances are allowed for the free expansion of the radiant plates and tee supports and for normal growth of the coils. Hevi Duty Electric Co., Milwaukee, Wis. (1289)

MANUFACTURERS' LITERATURE

Finishes for Aluminum

Characteristics of aluminum, mechanical finishes, chemical dip finishes and electrolytic oxide finishes are among the features of an attractively illustrated booklet. Aluminum Co. of America, Pittsburgh, Pa. (1290)

X-Ray and the Foundry

Interesting treatise on this subject setting forth how the X-ray has now come to the fore as a tool of the testing laboratory. Kelley-Koett Mfg. Co., Inc., Covington, Ky. (1291)

Cor-Ten and Man-Ten

Pamphlet describing high-tensile steels developed to meet the needs of the transportation industry. United States Steel Corp., Pittsburgh, Pa. (1292)

Extensometer

The Kenyon-Burns-Young extensometer is described and illustrated in Bulletin 128. It is claimed that this equipment determines the deep drawing qualities of sheet metal accurately. Illustrated. Baldwin-Southwark Corp., Philadelphia, Pa. (1293)

What Scientists Say of Leitz Ultropak

Bulletin No. 17 describes the personal experiences and applications to which Ultropak has been placed by scientific workers in various fields. E. Leitz, Inc., New York, N. Y. (1294)

Heat and Corrosion Resistant Alloys Heated By Gas

Bulletin C1-A illustrates a number of complex castings made from Q-Alloys which are recommended for pipe fittings, furnace parts, etc. General Alloys Co., South Boston, Mass. (1295)

Special Atmospheres in the Heat Treatment and Brazing of Metals

A reprint of the above article by C. L. West, Research Engineer, is offered by The Electric Furnace Co., Salem, O. (1296)

Wet Patch

The manufacturer claims that excellent results are obtained when P. B. Sillimanite wet patch is used to patch crucible furnaces, electric furnaces, etc., because of its high refractoriness negligible shrinkage and stubborn resistance to slag attack. The Chas. Taylor Sons Co., Cincinnati, O. (1297)

Sand Control in the Foundry

A colorful pamphlet lists the major causes of casting defects and inferiorities and states that they may be avoided by the use of the proper sand control equipment. Illustrated. Harry W. Dietert Co., Detroit, Mich. (1298)

Silico-Manganese Spring Steel

Extreme care is taken in processing this steel to avoid imperfections, in rolling to obtain cold-shearing qualities and in controlling the uniformity of the structure to insure both high inherent fatigue resistance and uniform heat treating characteristics, according to the manufacturer. Illustrated. Bethlehem Steel Co., Bethlehem, Pa. (1299)

Salt Bath Furnace

The Ajax-Hultgren electrically heated salt bath was designed to meet the metallurgical requirements of liquid heat treating operations. Bulletin 103 lists some of the advantages of the furnace. Illustrated. Ajax Electric Co., Inc., Philadelphia, Pa. (1300)

Screw Steel

A recent development in the production process of Union free cut, Bessemer (S.A.E. 1112) largely eliminates abrasive elements associated with wear on cutting tools. Longer tool life and uniformity of the steel are claimed among its advantages. Union Drawn Steel Co., Massillon, O. (1301)

Stainless Steel Castings

An attractive booklet contains useful information on the subject. Typical analyses, characteristics and suggested uses are listed. Joseph T. Ryerson & Son, Inc., Chicago, Ill. (1302)

Heavy Duty Refractories

This handbook contains complete descriptions, applications, tables and illustrations of standard shapes. Many useful engineering data are included. Norton Company, Worcester, Mass. (1303)

Braze-Rite Furnace

This furnace, developed principally for brazing sintered carbide cutting tools, provides for localized heat to be applied only to the portion of the tool to be brazed. Illustrated. Firth-Sterling Steel Co., McKeesport, Pa. (1304)

The New Arc Welding Technique

The new "Shield-Arc S.A.E." Welder which is described and illustrated in a colorful pamphlet gives an arc to suit every application according to the manufacturer. At any desired value of welding current, a wide variation in penetration can be secured, permitting the desired quality of weld with greater welding speed. The Lincoln Electric Company, Cleveland, O. (1305)

Fluxing, Deoxidizing and Hardening Alloys

Ajax alloys (phosphor copper, phosphor tin, nickel copper, manganese copper and silicon copper) are the subjects of a new leaflet issued by the Ajax Metal Co., Philadelphia, Pa. (1306)

Electromet Review

This publication, whose purpose is to bring "News and Views of Alloy Steels and Irons" to the reader, contains interesting items. Electro Metallurgical Co., New York, N. Y. (1307)

Cable Accessories

Publication GEA-1839 lists and describes the materials required for work involving the jointing and terminating of insulated cable. Illustrated. General Electric Company, Schenectady, N. Y. (1308)

Properties of OFHC Copper

An attractive booklet contains reprints of three papers relating to the above subject. Photographs, diagrams and photomicrographs are used to illustrate them. United States Metals Refining Co., New York, N. Y. (1309)

Finish Baking and Drying Ovens

Ovens for various finishing processes are featured in two new bulletins, pages 101-104 of Section A-5, which have been issued by the Despatch Oven Co., Minneapolis, Minn. (1310)

Gas Fired Furnace

The manufacturer of the gas fired Lindberg Cyclone furnace for heating at temperatures from 250 deg. F. to 1400 deg. F. claims that the heating rate is remarkably fast, and either open or extremely dense charges are handled with equal facility. Illustrations. Lindberg Engineering Co., Chicago, Ill. (1311)

3300 Deg. Super Refractory

An illustrated catalog devoted to "Shamva" Mullite contains information regarding its background, characteristics and uses. Mullite Refractories Co., Shelton, Conn. (1312)

Electro-Granodizing

This process which, according to the manufacturers, provides a rust-proof, paint-receptive surface combining the advantages and eliminating the disadvantages of other protective coatings in commercial use today is described in an illustrated leaflet of the American Chemical Paint Co., Ambler, Pa. (1313)

Potentiometer Control Pyrometer

The principles, operating details and methods of application of the Stabilog Potentiometer Control Pyrometer are described in Bulletin 194-1. Related equipment for automatic temperature control is also covered. The Foxboro Co., Foxboro, Mass. (1314)

Alloy Castings

Corrosion resistant and stainless steel castings are the subject of a new booklet. Chemical and metallurgical properties of these castings are included. Illustrated. Michiana Products Corp., Michigan City, Ind. (1315)

MoTung High Speed Steel

An illustrated booklet devoted to the above, contains information under these divisions: working and treatment, surface protection, high heat temperatures, drawing temperatures, effect of treatments, etc. An index is included. Universal Steel Co., Bridgeville, Pa., and Cyclops Steel Co., Titusville, Pa. (1316)

Surface Hardening by Induction

The TOCCO Process which, it is claimed, reduces hours of surface-hardening time to seconds and produces a scientifically regulated, exact result, is discussed in an attractive illustrated leaflet of The Ohio Crankshaft Co., Cleveland, O. (1317)

Electric Welding Products

Catalog No. 101 contains information on welding rods (recommended uses for the different types, physical properties, welding procedure, etc.); miscellaneous apparatus, and Wilson arc welding machines. Air Reduction Sales Co., New York, N. Y. (1318)

Spectrometric Equipment

Catalog D-221 is devoted to the above equipment. Basic theory and designs are described as well as the various types of instruments. Illustrated. Bausch & Lomb Optical Co., Rochester, N. Y. (1319)

Sonittep Products

This booklet discusses heat loss and its control. The advantages of Sonittep insulating cement and its uses are listed. Instructions for its application are included. Graphs. George F. Pettinos, Inc., Philadelphia, Pa. (1320)

High Frequency Electric Power Converters

According to illustrated pamphlets, this company manufactures high frequency electric converters for use in conjunction with numerous industrial induction heating applications such as, the heating of metals for hardening, tempering, drop forging, melting, case hardening, degassing, etc. Lepel High Frequency Laboratories, Inc., New York, N. Y. (1321)

CURRENT NEWS ITEMS

Dr. Jacobus Receives Morehead Medal

The Morehead Medal for the year 1935 has been awarded to Dr. David Schenck Jacobus for his outstanding leadership in the formulation of codes and procedures which have made fusion welding acceptable. The medal was presented to Dr. Jacobus during the opening session of the 37th annual convention of the International Acetylene Association held at Hotel Jefferson in St. Louis Wednesday, Nov. 18.

The Morehead Medal is awarded annually by the International Acetylene Association to the person or persons who, in the judgment of its officers and board of directors, have done most to advance the industry or the art of producing or utilizing calcium carbide or its derivatives. The award was established in 1922 by the Hon. John Motley Morehead, formerly United States Minister to Sweden, in honor of his father, the late James Turner Morehead who, in 1892, sponsored the experiment which lead to the discovery of the electric furnace method of producing calcium carbide.

Perkin Medal Award

Dr. Thomas Midgley, Jr. has been elected to receive the Perkin Medal of the Society of Chemical Industry for 1937. The medal is awarded annually for valuable work in applied chemistry and will be presented this year to Dr. Midgley for his work in the development of antiknock motor fuels, safe refrigerants, etc. The selection is made by a committee representing the five chemical societies in the United States. The medal will be presented on January 8 at a meeting to be held at The Chemists' Club. Details will be announced later.

Symposium on High-Strength Constructional Metals

This symposium comprises five extensive technical papers and discussion presented at the 1936 A. S. T. M. regional meeting. The papers cover the chemical and physical properties and manufacturing and fabricating properties of metals and alloys applied for various constructional applications including buildings, ships, automobile bodies, airplane wings, tanks, etc.

The papers give the latest information and data on the following: Carbon and low-alloy steels, corrosion-resisting steels, alloys of copper, alloys of nickel, and alloys of aluminum and magnesium. There are a great many charts and tables of data in the symposium, thus presenting much of the valuable and extensive information in condensed form.

Copies of the publication of 126 pages can be obtained from A. S. T. M. Headquarters, 260 S. Broad St., Philadelphia, at $1.25 heavy paper binding; $1.50, cloth binding.

New Research Laboratory for Armco

Construction of a modern research laboratory to replace the research building which was leveled by an explosion in December, 1935, was announced today by The American Rolling Mill Co.

As a result of an extensive research program of long standing, Armco has developed many special grades of iron and steel sheets which comprises a large part of the company's production. Since the demolition of the laboratories, the management has been studying the problem and has now decided to proceed with the construction of a new building with proper and modern facilities to house this most important function.

This building, to be erected in Middletown of porcelain enameled sheets, other decorative metal products, and glass blocks, will cost approximately $260,000, exclusive of equipment. A multiple-story building of equal floor space but of conventional construction, would cost about $400,000, the announcement said.

The laboratory, a single-story building designed and to be erected by The Austin Co., national organization of industrial engineers and builders, is the outgrowth of extensive research which led to the use of sheet iron and steel as building materials. The American Rolling Mill Co.'s development of the continuous process for rolling sheets is of far-reaching interest to the building trade because this method of rolling sheets greatly widened the use of sheet metal through the substantial reduction in cost.

Fritz Medal to A. N. Talbot

Arthur Newell Talbot, professor emeritus of engineering in the University of Illinois, has been awarded the 1937 John Fritz Gold Medal, highest of American engineering honors. Prof. Talbot, who is 79, was cited as "molder of men, eminent consultant on engineering projects, leader of research, and outstanding educator in civil engineering." The award is made annually for notable scientific or industrial achievement by a board composed of 16 past-presidents of the four national societies of civil, mining and metallurgical, mechanical, and electrical engineers.

Prof. Talbot has been president of the American Society of Civil Engineers, the Society for the Promotion of Engineering Education, and the American Society of Testing Materials, and is a member of many other professional organizations. He received the Washington Award in 1924, the Turner Medal in 1928, the Henderson Medal of the Franklin Institute in 1931, and the Lamme Medal of the Society for the Promotion of Engineering Education in 1932. He is the author of many technical articles, and has contributed to professional journals.

Among the recipients of the Medal have been Lord Kelvin, Thomas Edison, Guglielmo Marconi, Elihu Thomson, John R. Freeman, John F. Stevens, Elmer A. Sperry, Daniel C. Jackling, M. I. Pupin, J. J. Carty, J. Waldo Smith, Frank Julian Sprague, and William Frederick Durand.

Aircraft Tubing Data

Those interested in aircraft engineering will be rewarded in studying a publication recently issued by the Summerill Tubing Co., Bridgeport, Pa. It is entitled "Aircraft Tubing Data" and contains "a great deal of information that is absolutely new." This is particularly true of the column strength curves which are plotted for the first time to cover 75,000 lbs. and 55,000 lbs. per sq. in. minimum yield. The data on properties of steel tubing are also assembled in a more commercial form for quick reference. There are 40 pages of data and charts. It is available at a cost of $1.00.

Luncheons by General Motors

Prior to and during the National Automobile Exposition in New York, Nov. 11 to 18, two luncheons were given by the General Motors Corp. which were of unusual interest.

On Nov. 10, in the Empire Room of the Waldorf-Astoria Hotel, a luncheon was tendered to Charles F. Kettering, vice president in charge of research of General Motors, by Alfred P. Sloan, Jr., president, in honor of the invention 25 yrs. ago by Mr. Kettering of the electric self-starter. Some 200 business executives, editors and professional men were in attendance.

A de-luxe Cadillac touring car of 1911 was exhibited on the stage and a self-starter of that vintage was unveiled during the post-prandial speeches. These were delivered not only by Mr. Sloan and Mr. Kettering, but also by Edwin C. Hill, E. V. ("Eddie") Rickenbacker, Daniel H. Cox and W. A. Harriman, all associated with subsidiary units to General Motors.

The other luncheon was tendered to editors of trade and professional papers at the University Club, Friday, November 13, at which about 75 sat down. The after-luncheon discussion was in charge of O. E. Hunt, chief engineer, who solicited questions which were interestingly answered by Mr. Kettering, the honor guest, and by Mr. Hunt and other representatives of the organization.

The permanent exhibition on the third floor of the International Building, Rockefeller Center, New York City, will hereafter be known as the Metals and Plastics Bureau. Diversification of the displays which constantly show new developments in the metals industry and the plastic industry, has resulted in a sustained demand for a name to indicate the scope of its activities.

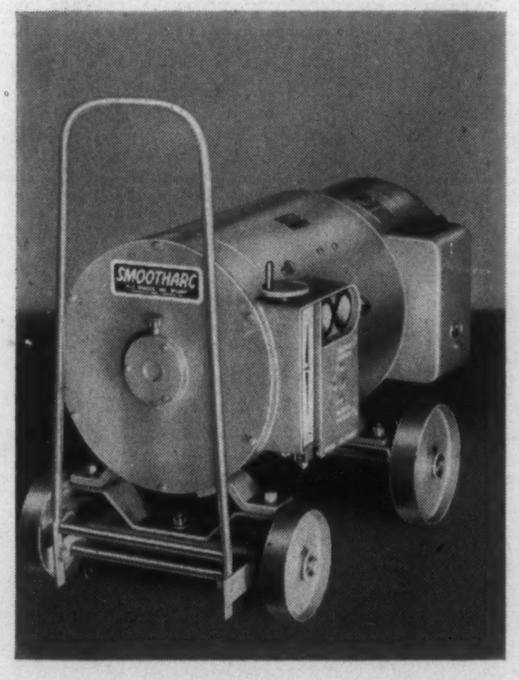
Establishing a permanent center for the display of metals, alloys, plastics and finishes, so that improved products and new applications could be examined at leisure, was a service rendered by its predecessor and the Metals and Plastics Bureau continues unaltered such activities.

NEW EQUIPMENT AND MATERIALS

New Line of P&H "Smootharc" Welders

The Harnischfeger Corp. of Milwaukee announces a new line of "Smootharc" welders featuring simplified design not only in outward appearance, but in operation as well with single current control, self-excitation and internal stabilization. These new welders are built in both vertical and horizontal types for stationary or portable mounting. The vertical units, compactly and uniformly designed, come in three sizes, 75, 100 and 150 amps. The horizontal units in 200, 300, 400 and 600-amp. capacities, are streamlined to minimize projecting parts, and present a neat compact appearance, all of which assure easy portability.

All sizes of the new P&H-Hansen Welders are provided with single current control, made possible by the patented design of shifting generator brushes. Through the medium of a micrometer screw device the brush shifting gives an infinite number of current settings. Open circuit voltage is maintained at a desirable high value at all current settings through the exclusive P&H design. The voltage regulation is automatic and requires but a turn of the hand wheel control to adjust the welding current. All of which permits easier, faster and better welding.



Self-excitation, an additional feature, is accomplished through a set of auxiliary brushes placed ahead of the main brushes and connected to an auxiliary shunt winding. By means of the specially designed generator, the auxiliary brushes operate in a magnetic field independent of the main field. The auxiliary brushes attached to the main brush ring are shifted simultaneously with the main brushes, thus regulating the proper amount of excitation made available at each current setting.

Through the use of interpole winding extended to the main pole shoes in such a manner that it serves the dual function of interpole winding, all "Smootharc" Welders are internally stabilized. Speedy arc recovery is secured through the combination of short circuit winding and the magnetic bridge located in the main field magnetic circuit.

In this new line of welders the generator instruments are concentrated in a single control panel built into the side of the generator frame. The a.c. motor starting box is built into the side of the motor housing. The streamlined appearance is accomplished through the use of all rolled steel and arc welded construction. All steel parts, field ring, pole shoe, etc., are annealed to give the highest possible quality magnetic field for generator fluxes.

New Low Temperature Brazing Alloy Sizes

The intense interest in low temperature brazing, together with the wide and growing variety of purposes for which silver brazing alloys are being used, have made it necessary for Handy & Harman, 82 Fulton St., New York, makers of "Sil-Fos" and "Easy-Flo," to add new sizes and forms to their standard price list to more promptly meet the increasing requirements.

Prices of these two alloys have not changed but additions to the standard sizes formerly carried in stock have now been included in a new combined price list covering Sil-Fos and Easy-Flo as well as Handy Flux, the use of which is necessary if full advantage is to be taken of the brazing alloys' low melting points. The new price list became effective Monday, Nov. 2.

To the former stock sizes of Sil-Fos—used for joining non-ferrous metals—a new strip thickness, 0.005 in. has been added in widths of ¼ in. or more. To the wire forms standard with Easy-Flo until now, a new wire size 3/64 in. has been added and four new gages of strip 0.020, 0.010, 0.005 and 0.003 in.-¼ in. or more in width, which should meet practically all requirements. For special applications, additional forms and sizes including washers, circles, rings and filed or powdered forms are still available and prices can be obtained on application.

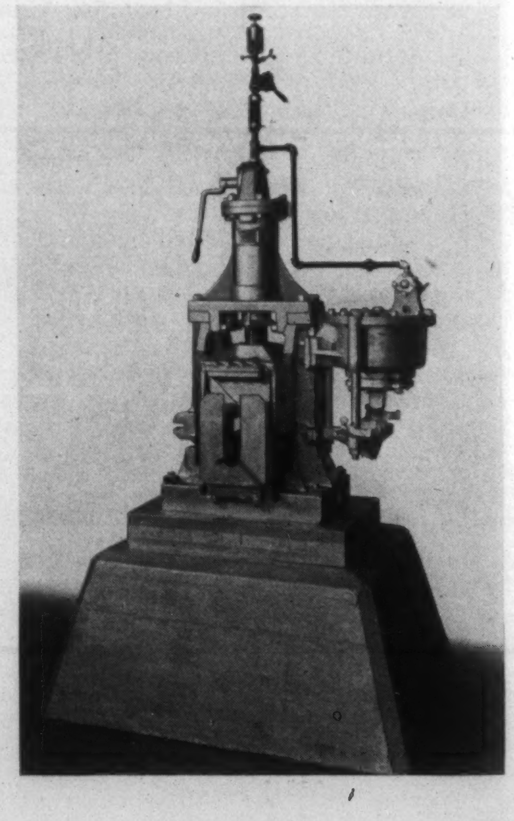
The increased use of these alloys is attributed to their exceptionally low melting points and the strong, ductile joints they make. Sil-Fos, free flowing at 1300 deg. F., joins copper, brass and bronze permanently and at low cost while Easy-Flo requires only 1175 deg. F., the lowest melting point of any brazing alloy giving high strength. The latter is used with both ferrous and non-ferrous metals and especially for joining steel, stainless steel, Monel metal and other Cu-Ni and Cr-Ni alloys as well as dissimilar metals such as copper to steel. Both alloys, because of their low flow points and the speed with which they can be applied, join metals without damaging physical qualities. Because Handy Flux is entirely fluid and active at 1200 deg. F., full advantage can be taken of the low melting points of these two brazing alloys.

In keeping with the growing use of low temperature brazing alloys, distributing and servicing facilities have been arranged throughout this country and Canada. Standard sizes can be obtained promptly from Handy & Harman with plants in New York, Bridgeport, Providence and Toronto, Canada, and from distributors located in all of the principal industrial centers in the country.

Improved Rod Straightener and Shear Machine

An improved rod straightener and shear machine is announced by The American Foundry Equipment Co., 555 S. Byrkit St., Mishawaka, Ind. The "American Rod Straightener and Shearer" was designed for reclamation of rods, bolts, wire and nails. It will reduce scrap piles, save labor and materials and pay profits through salvaged materials which formerly constituted waste. Laborers, formerly occupied in straightening rods by hand, can be put to more profitable work in other capacities. Rapidity of operation in both straightening and shearing is limited only by the speed of the operator in feeding stock into the machine.

The American Rod Straightener and Shear machine is made in all sizes from a small hand operated model with a maximum straightening capacity of ¼-in. rods to a large compressed air unit with maximum straightening capacity of 2½-in. rods. With the exception of the hand operated model, all of the machines are operated by compressed air, 60 lbs. being the minimum pressure for satisfactory operation.



The straightening mechanism is composed of manganese steel dies which close as a contracting square on the rod or bar and deliver an impact on four sides simultaneously. Operation is controlled and the force of the blow is regulated by a hand control lever which actuates the air throttle valve. A gagger attachment is obtainable on several of the models.

The machine is constructed of cast steel with the exception of cylinder parts which are cast iron. Maintenance expense is practically eliminated because of the sturdy construction. Operating expenses are negligible as the machine does not require skilled labor.

Armco Galvanized "Paintgrip" Sheets

Full commercial production of a new kind of galvanized sheet that assures a good paint bond on iron and steel products has been announced by The American Rolling Mill Co., of Middletown, Ohio. Introduction of "Armco Galvanized Paintgrip" sheets follows several years of intensive research on the part of Armco's metallurgists and the technicians of the Parker Rust-Proof Co. This new kind of galvanized sheet metal can be painted without special treatment of the surface by the user.

Armco Paintgrip sheets, the manufacturers say, are chemically treated to produce a fine crystalline phosphate coating which in itself is neutral to paint (being neither acid nor alkaline) and keeps the paint from direct contact with the zinc surface. This coating is an integral part of the sheet and is slightly granular in nature.

Armco Paintgrip sheets are available in any of the grades of galvanized sheets manufactured by the company. Analysis of the base metal can be that of Armco Ingot Iron, plain or copper-bearing steel. When it is required, all grades of these sheets can be supplied stretcher leveled. Forming qualities of Armco Paintgrip sheets are the same as untreated galvanized sheets. They may be soldered satisfactorily with the use of hydrochloric acid as a flux.

Formation of a Paintgrip coating on metal is dependent upon the fact that phosphoric acid solutions will dissolve zinc phosphate within certain definite limits. Passing zinc coated iron or steel products through such a solution results in the formation of the Paintgrip coating which becomes an integral part of the metal surface at the point of solution. Reaction takes place with the evolution of hydrogen, continuing until the metal surface is completely converted to a crystalline phosphate coating.

Mechanical Device for Handling Heat-Treated Materials

A cooperative arrangement has been effected between the Ajax Electric Co., Inc., Philadelphia, and Continental Engineers, Inc., Chicago, which should be of considerable interest to prospective furnace purchasers. The Ajax Electric Co., Inc., has developed an extremely economical and low maintenance salt bath known as the Ajax-Hultgren furnace, which may be used for liquid heat treating, case hardening or other metal heating operations. It is regarded as a large step in advance of the present art, and is fully covered by broad patents. Continental Industrial Engineers, Inc., have developed and patented a comprehensive system which mechanically moves materials being heat treated through a predetermined cycle, as for example, preheating in cyanide pots, quenching, rinsing, washing and drawing.

Because of the many advantages of the Ajax-Hultgren furnace, it fits in ideally into the Continental system. The Continental system makes possible very economical and uniform heat treating and practically eliminates handling. Since all operations are timed and mechanically controlled, both as to temperature and speed, each part must be exactly like the other parts.

It is anticipated that this cooperative agreement will be very much to the interest of furnace users as they may purchase this type of equipment with the assurance that the two outstanding companies in this field are cooperating to see that the resultant product is the best obtainable.

Acitrol 100, a New Inhibitor

Based on the acknowledged principle of setting up an electrolytic insulating film where steel is attempting to dissolve, E. F. Houghton & Co., Philadelphia, introduces a new inhibitor, "Acitrol 100." This exerts an electrolysis control which differentiates between the productive and nonproductive galvanic couples present in a pickling solution. It is especially designed to include high dielectric strength, great cathodic affinity and freedom from breakdown.

Acitrol 100 is a synthetically manufactured, pure chemical powder inhibitor which dissolves rapidly in either strong or weak acid solutions, and leaves no greasy residue or stain on the steel. The loss of an inhibitor due to breakdown determines its ultimate cost and the economy of Acitrol 100 is proven in its showing of practically no breakdown at boiling temperatures over long periods of time. Acitrol 100 costs less to use per ton of steel both because of its initial strength which is far above the average, and its stability.

A New Coated Electrode

Metal & Thermit Corp., 120 Broadway, New York, announces an addition to its line of Murex heavy coated electrodes for arc welding. The new electrode, known as "Murex Type N," is designed for bridging gaps where fit-up between plates is poor and, in the smaller sizes, may be used on vertical and overhead work, or to make rapid, single pass welds on light gage materials. In addition, it will produce clean, sound, single or multiple pass fillets.

The physical properties of the metal deposited by the Murex Type N electrode are said to range from 74,000 to 84,000 lbs. per sq. in. in tensile strength with 26 to 24 per cent ductility. The new electrode is also said to work equally well with either d.c. or a.c. and may be used either with straight or reversed polarity.

Cements *that* Stand Up!

"SHAMVA" MULLITE
Shamva Products

The same high temperature performance as "Shamva" Mullite bricks and shapes

If you wish the best grade of cement it is possible to get, for bonding brick work—for a wash to resist flame cutting, and slag, gas and dust penetration—for ramming linings—and for repairs of every kind, you will find it in one of the following "Shamva" products:

SM40—*Mortar Cement*—Stubbornly resists flame cutting and the penetration of corrosive and dust-laden gases. A high quality bond for brick work.

SM50 — *Dry Patching Cement* — Air setting. Sets cold and forms a very strong bond. Excellent for small patching, coating walls, or pointing up cracks. An ideal wash for brick work.

SM60—*Plastic Patching Cement* — Molds to any shape, for furnace interiors and doors or monolithic structures. Perfect for filling holes or for replacing entire brick sections.

SM70—*Ramming Cement* —For ramming furnace linings, special shapes or monolithic walls with air hammers. Sets readily, does not shrink, giving long service.

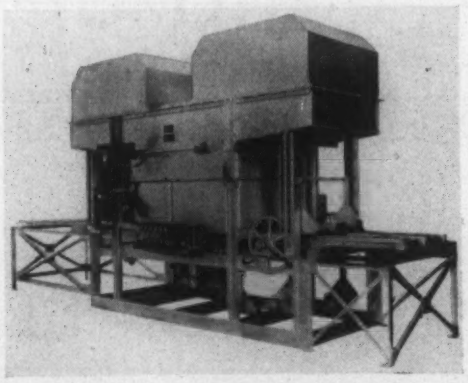
MULLITE
THE 3300° SUPER-REFRACTORY

Automatic, Vapor-Type Degreaser

The automatic, conveyorized, vapor-type of Detrex Degreaser has been recently designed and built by the Detroit Rex Products Co., 13005 Hillview Ave., Detroit, for the cleaning of heavy gage metal parts. This machine is equipped with a 2-strand, cross-rod type of conveyor, which has a variable speed drive. There are 17 special fixtures suspended from this conveyor on 30 in. chain centers to handle the work baskets through the degreaser. Roller-type gravity conveyors at each end of the machine provide automatic loading and unloading. Electric immersion heaters, and thermostatically controlled magnetic relay and line switch are used. The machine is also equipped with a full automatic vapor level control device.

This model of degreaser is built in various sizes to accommodate production requirements. The particular machine shown is 20 ft. long, 6 ft. 3 in. wide by 9 ft. 8 in. high. It has a rated production capacity of over 6,000 lbs. of heavy gage metal parts per hr. at a conveyor speed of 1 ft. per min. Parts are received on this gravity roller conveyor loaded in grill-type metal baskets having perforated plate separators. These work baskets are automatically lifted from the conveyor fixtures and carried through the machine. While in the machine, the parts are subjected to vapor cleaning in pure solvent vapor—either "Perm-A-Clor" or "Triad Safety Solvents" being used. The baskets of work on being conveyed out the opposite end of the machine are automatically transferred onto the gravity rolls at the exit end. From here they are conveyed to the following heat treating or finishing operations (depending upon the requirements of the work). The complete cycle of vapor cleaning requires only about 4½ min. The work is removed from the machine perfectly free of oil and dry.



Despatch Convected Air Gas Fired

A radical departure from the conventional present day tempering and drawing furnace, the new "Despatch Dense Load Convected Air Gas Fired Furnace" of the Despatch Oven Co., Minneapolis, Minn., sets new high standards for performance.

The new design incorporates numerous features which assure positive uniformity of tempering and drawing results, precise temperature control, high production capacity, genuine operating economies, rapid heat transfer and many other operating advantages.

Operating uniformity is guaranteed to be plus or minus 5 deg. F. at 1200 deg. F. Preheating is rapid because large volumes of air under high pressure are driven through the loads. Without the use of complicated step-down control systems, Despatch Dense Load Furnaces maintain the set operating temperature within 5 deg. F. plus or minus at 1200 deg. F. There is no overshoot of temperature. They offer greater production per unit because the heat transfer rate is high and the furnace operates with high efficiency.

Gas is an economical and low priced fuel. Naturally the cost of drawing and tempering is lower per pound of material processed than when using a more expensive heating medium, such as electricity. High capacity high pressure blower forces heated air uniformly through every portion of the load. Parts are always drawn and tempered uniformly no matter how dense the load.

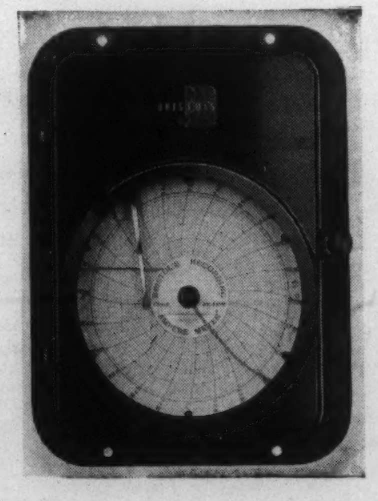
Low working height, top loading system, and minimum floor space requirements make the furnace ideal for the crowded commercial shops and production departments. Recessing of units is not required. All furnaces are designed for floor mounting. They are arranged for temperatures up to 1200 deg. F. Quick changes from one temperature to another when required to smoothly handle various production demands eliminate wasted time and bring about increased production.

Ruggedness of the design and construction of this furnace assures uniformly and thoroughly tempered and drawn parts with a minimum of operating cost, time, and maintenance expense.

New Line of Round Chart Recording Voltmeters and Ammeters

A new line of "Round Chart Recording Voltmeters and Ammeters" is announced by The Bristol Co., Waterbury, Conn. These new instruments have been developed to take care of the requirements of electric utilities for accurate, rugged instruments that are easy to use and service. They also are intended to fill the requirements of industrial plants, especially for process work where voltage and current affect the quality and cost of manufacture of the product.

The new electric recorders are offered in models for wall, switchboard, flush panel, and pole mounting, and for portable use. These instruments are housed in a very practical moisture-, fume-, and dust-proof case made of an aluminum alloy. In the design of this case, attention was paid to beauty so that it would harmonize with other modern fixtures and pieces of apparatus.



The measuring element is a separate unit that can be easily replaced by removing only three screws from the mounting. The pen-arm is inverted and is pivoted at the top in such a way that the pen pressure against the chart is delicately controlled by gravity. This eliminates any possibility of sluggishness due to the pen arm becoming bent. The pen arm is equipped with a convenient micrometer zero adjustment and also a replaceable chromium plated tip, which may be removed by loosening only one screw. These new electric recorders are offered with spring-driven and other electric Telechron clocks.

Welding Robot Uses Standard Rods

New impetus was given to the development of arc welding in all kinds of metal fabrication work with the announcement of an entirely new automatic welding head; the first of its kind to use standard coated rods, thus putting welding on a mass production basis with the uniform high-speed results obtainable only with this type of electrode. This new automatic welding machine, developed and perfected by the Harnischfeger Corp. of Milwaukee is a true robot operated by remote control. By eliminating the hand-operated electrode holder, this automatic machine makes it possible to use a higher current with welding heats as much as 60 per cent higher, increasing tremendously the speed of producing welding pieces.

Up to 50 standard welding rods are loaded in a magazine and then fed automatically to the welding position. As one electrode is consumed, the remaining butt is ejected and a new, full-length rod is fed into place. The renewing operation takes less than a split second. During this feeding operation, the work table stops and then starts again automatically as the new electrode makes the electric contact. The action is so swift that no break in the welded bead is evident. The arc length is automatically regulated at a constant point during the welding operation. Though the working surface be irregular, there is no apparent variation in the penetration or appearance of the bead.

This new machine can be used on flat work of any length, on circular pieces and, with pantograph attachment, to any shape. It is adaptable for use on lathes, planers, rotating tables, boring mills and with wall cranes, for welding long girders, etc. In addition to its greater speed and accuracy it substantially reduces the cost of many welded pieces.

"Hackett K-Copper"—A New Copper Alloy

A new copper alloy, that will be especially interesting to manufacturers and users of welding equipment, is being marketed under the name of "Hackett K-Copper" by its producers, the Hackett Brass Foundry, Detroit.

Hackett K-Copper is claimed to combine the physical properties of steel and bronze with the high electrical and heat conductivity of copper. Compared with pure copper it has equal corrosion resistance, the same coefficient of expansion, coefficient of resistivity and modulus of elasticity. It has a hardness of 70 to 80 Rockwell B (125 to 150 Brinell), ultimate strength of 70,000 lbs. per sq. in., elongation approximately 20 per cent, reduction in area 50 per cent. In drawn rod 83 per cent, it has the electrical conductivity of pure drawn copper, in forged form 75 to 85 per cent that of forged copper.

The alloy is available in bars, forgings and castings and is being widely used for welding tips and holders. The producer uses it in the manufacture of a wide range of standard and special designs of spot welding tips which have demonstrated important savings for operations of welding machines. The Hackett K-Copper tips are reported to mushroom less easily than pure copper, require dressing less frequently and deliver a greater number of welds per tip.

New Sintered Carbide Plant

The Firth-Sterling Steel Co., McKeesport, Pa., has announced that it will erect at its local plant a new building as a result of increasing production demands. The building is to be two stories in height and will be erected so that more floors can be added. It is to be used for the manufacture of tungsten carbide tools and dies, merchandising under the trade names of "Firthaloy" and "Firthite." It is to be 210 ft. long, 95 ft. wide and will be located adjacent to the existing buildings at Demmler in such a manner that it can be extended in three directions.

The construction of the new building has started and is designed in an ultra-modern style, in keeping with the Firthite-tungsten carbide process which is something new in the field of metallurgy. The building is to be equipped with dust removal and recovery system, and parts of it, where the manufacturing process is particularly noisy, are to be sound-proofed. As the manufacturing process of tungsten carbide necessitates extremely hard wearing surfaces, as well as clean working space, the interior walls and floors will be given special finishes to meet these requirements and air will be filtered and conditioned. The Rust Engineering Co., Pittsburgh, has been awarded the contract for the building and expects to complete the work the latter part of this year.

New Corrosion Resistant Specialties for Use in Plants Handling Corrosive Agents

Two new products designed to meet corrosive problems in a variety of plants where acid, alkali and other corrosive agents are encountered have just been announced by manufacturers. One of these is a Monel caster for trucks, hampers and wheeled conveyors of all kinds. Available in both the stationery and swivel roller type, it is adapted to use in chemical, processing plants, laundries, dry cleaning and similar establishments where the corrosive materials are liable to spill over on the floor.

Metal parts of the caster are entirely of Monel, including bearings, shaft and spacers. Wheels are of a special rubber composition. The casters are manufactured by the Bassick Co., Bridgeport, Conn.

The second piece of equipment is designed for use in similar plants and is a special adaptation of an earlier piece of equipment. This is the Whitehead graduated type Monel pail, now made available in standard sizes of 12, 14 and 16 qts. Its development follows the general acceptance of the non-graduated type of Monel pail which has been on the market for several years.

Bottom and sides are of 0.037 in. Monel electrically seam welded. The chime also seam welded is 0.078 in. thick and is seam welded to project ½ in. below the bottom. Monel ears are spot welded to the sides. The handle is 5/16 in. Monel rod and the rim is rolled over a 3/16 in. wire. The seam cannot break open and there are no rivets at which leaks can start.

AT RIGHT—*Triple-Control Hump hardening furnace, made by Leeds and Northrup Company, Philadelphia, Pa. Armstrong's EF-22 Insulating Fire Brick guard the highly important "filler ring" (indicated by a broken line on the photograph.)*

ARMSTRONG'S High Temperature Products meet the insulation requirements of every type of furnace. Whether insulation is needed for a large open hearth furnace, or for use at a critical point in a small hardening furnace, there's an Armstrong Brick to do the job efficiently!

Armstrong's complete line of High Temperature Products includes: Armstrong's N-16, N-20, and A-25 Insulating Brick for temperatures up to 1600°, 2000°, and 2500° F., respectively, behind the refractory; and Armstrong's EF-22 and EF-26 Insulating Fire Brick for use without fire brick protection up to 2200° and 2600° F., respectively. These brick are made with technical expertness and care which assure uniformity and accurate sizing. Moreover, repeated testing keeps them consistently up to Armstrong's rigid specifications for quality.

Use of Armstrong's Brick provides accurate temperature control, savings in fuel, and speeding up of production. Write today for the free, illustrated booklet, "Armstrong's High Temperature Products." Armstrong Cork Products Co., Building Materials Division, 982 Concord St., Lancaster, Penna.

A troublesome job done easily by EASY-FLO PATENTED

BRASS
STEEL
EASY-FLO

—the low-temperature brazing alloy for low-cost joining of dissimilar metals

A ¾″ yellow brass tube, a stamped circular body of steel only .015″ thick—and a joint which must withstand constant vibration at temperatures up to 300 deg. F.—this was the problem in manufacturing this auto engine oil float.

The right answer was found in EASY-FLO Brazing Alloy. As in many other jobs, EASY-FLO in this case is producing sound, ductile joints without damage to the physical qualities of surrounding metal and does this work at surprisingly low cost.

These joints are made at the rate of 70 per hour per operator. The cost, including EASY-FLO, HANDY FLUX, oxygen, acetylene and labor, totals 1.69 cents per joint—a little over one and one-half cents for insurance against trouble in a joint where dependable strength is so important.

EASY-FLO offers high strength and economy in joining a wide variety of metals — steel, stainless steel, Monel Metal, Inconel, copper, brass, bronze, nickel and many other copper-nickel and chrome nickel alloys. Its low melting point—1175 deg. F.—makes it easy to guard against damage due to overheating. It flows rapidly, penetrates deeply, and offers good corrosion resistance.

●

Try EASY-FLO on your difficult or troublesome joining problems and on your regular production too. Write us for full information, or send details of your specific brazing job. We will be glad to cooperate with you.

HANDY AND HARMAN 82 Fulton St., New York

THEY'LL FIGURE ALL WEEK

to save a Penny!

WHEN you're turning out a product by the hundred thousands, a saving of even a fraction of a cent on production quickly runs into important money. No wonder engineers, designers, and shopmen burn the midnight oil, sweat over ways and means to trim costs.

In these round-table discussions Carnegie-Illinois Controlled Steels are getting increasingly important consideration. For it is now a matter of record that these steels are accomplishing remarkable savings.

In one plant, for example, they needed a steel that would give uniform response to heat treatment, that would forge readily, machine easily. They gave Controlled Steels a trial. Costs dropped—not one penny . . . not five cents . . . but 78¢ per part—and their production runs close to a quarter of a million parts a year.

What are Carnegie-Illinois Controlled Steels? Briefly, they are steels for forging, forming, heat treating and machining, in which *all* quality factors can be definitely pre-determined . . . steels in which the physical properties are kept consistently uniform in shipment after shipment. Scientific metallurgical control eliminates those "mysterious differences" which make it so difficult to obtain uniform results with ordinary steels.

It costs nothing to find out how they may be used to cut your steel bills or reduce your fabricating cost. We welcome the opportunity to discuss this important matter with you.
